The victory of the free traders was not, however, destined to be of long duration, as the protectionists obtained a majority in both chambers in the next Riksdag (1888). To the First Chamber protectionists were almost exclusively elected, and in the Second all the twenty-two members for Stockholm were disqualified, owing to one of their number not having paid his taxes a few years previously, which prevented his being eligible. Instead, then, of twenty-two free traders representing the majority of the Stockholm electors, twenty-two protectionists, representing the minority, were elected, and Stockholm was thus represented in the Riksdag by the choice of a minority in the capital. This singular way of electing members for the principal city in the kingdom could not fail further to irritate the parties. One result of the Stockholm election came at a convenient time for the Themptauder ministry. The financial affairs of the country were found to be in a most unsatisfactory state. In spite of reduced expenses, a highly estimated revenue, and the contemplated raising of taxes, there was a deficit, for the payment or discharge of which the government would be obliged to demand supplementary supplies. The Themptauder ministry resigned. The king retained, however, for a time several members of the ministry, but it was difficult to find a premier who would be able, during the transition from one system to another, to command sufficient authority to control the parties. At last Baron Gillis Bildt, who, while Swedish ambassador in Berlin, had witnessed the introduction by Prince Bismarck of the agrarian protectionist system in Germany, accepted the premiership, and it was under his auspices that the two chambers imposed a series of duties on necessaries of life. The new taxes, together with an increase of the excise duty on spirits, soon brought a surplus into the state coffers. At a council of state (Oct. 12, 1888) the king declared his wishes as to the way in which this surplus should be used. He desired that it should be applied to a fund for insurance and old age pensions for workmen and old people, to the lightening of the municipal taxes by state contributions to the schools and workhouses, to the abolition of the land taxes and of the obligation of keeping a horse and man for military service, and, lastly, to the improvement of the shipping trade; but the Riksdag decided to devote it to other objects, such as the payment of the deficit in the budget, the building of railways and augmentation of their material, as well as to improvements in the defences of the country.

Baron Bildt resigned as soon as the new system seemed settled, making room for Baron Gustav Akerhjelm. The latter, however, also soon resigned, and was succeeded on the 10th of July 1891 by Erik Gustav Boström, a landed proprietor. The protectionist system gained in favour on the expiry of the commercial treaty with France in 1892, as it could now be extended to articles of industry. The elections of 1890, when the metropolis returned free traders and Liberals to the Second Chamber, certainly effected a change in the latter, as the representatives of the towns and the old "Landtmanna" party joined issue and established a free-trade majority in the chamber, but in the combined meetings of the two chambers the compact protectionist majority in the First Chamber turned the scale. The customs duties were, however, altered several times in accordance with market prices and ruling circumstances. Thus in 1892, when the import duty on unground corn was reduced from 2s. 10d. to 1s. 5d., and that on ground corn from 4s. 9d. to 2s. 10d. for 100 kilogrammes, the same duties were also retained for the following year. They were also retained for 1894 at the request of the government, which desired to keep faith with their promise that while the new organization of the army was going on no increase of duties on the necessaries of life should take place. This measure caused much dissatisfaction, and gave rise to a strong agrarian movement, in consequence of which the government, in the beginning of 1895, before the assembling of the Riksdag, made use of its right of raising the two duties on corn just referred to, 3s. 7d. and 7s. 2d., which were afterwards somewhat reduced as far as seed corn for sowing purposes was concerned.

National Defence.

The question of customs duties now settled, that of national defence was taken up afresh, and in the following year the government produced a complete scheme for the abolition of the land tax in the course of ten years, in exchange for a compensation of ninety days' drill for those liable to military service, proposed to retain the old military system of the country and to strengthen the defences of Norrland, and the government bill for a reorganization of the army was accepted by the Riksdag in an extraordinary session. But it was soon perceived that the new plan was unsatisfactory and required recasting, upon which the minister of war, Baron Rappe, resigned, and was succeeded by Colonel von Crustebjorn, who immediately set to work to prepare a complete reorganization of the army, with an increase of the time of active service on the lines of general compulsory service. The Riksdag of 1900, in addition to grants for the fortifications at Boden, in the province of Norrbotten, on the Russian border, and other military objects, voted a considerable grant for an experimental mobilization, which fully exposed the defects and faults of the old system. In the Riksdag of 1901 E. G. Boström resigned, and was succeeded by Admiral F. W. von Otter, who introduced a new bill for the army reorganization, the most important item of which was the increase of the period of training to 365 days. The cost in connexion with the new scheme was expected to amount to 22 millions of kronor. The Riksdag, however, did not accept the new plan in its full extent. The time of drilling was reduced to 240 days for the infantry, to 300 days for the navy, while for the cavalry and artillery the time fixed was 365 days. The plan, thus modified, was then accepted by the government.

Franchise Reform.

After the elections in 1890, the alliance already mentioned between the old "Landtmanna" party and the representatives of the towns had the result that the Liberals in the Second Chamber, to whom the representatives of the towns mostly belonged, were now in a position to decide the policy which the two united parties should follow. In order to prevent this, it was proposed to readjust the number of the members of the Riksdag. The question was only settled in 1894, when a bill was passed fixing the number of the members of the Riksdag in the First Chamber at 150, and in the Second at 230, of which 150 should represent the country districts and 80 the towns. The question of protection being now considered settled, there was no longer any reason for the continued separation of the two "Landtmanna" parties, who at the beginning of the Riksdag of 1895 joined issue and became once more a compact majority in the Second Chamber, as they had been up to the Riksdag of May 1887. The influence of the country representatives was thus re-established in the Second Chamber, but now the demands for the extension of the franchise came more and more to the front, and the premier, Boström, at last felt bound to do something to meet these demands. He accordingly introduced in the Riksdag of 1896 a very moderate bill for the extension of the franchise, which was, nevertheless, rejected by both chambers, all similar proposals by private members meeting the same fate. When at last the bill for the reorganization of the army, together with a considerably increased taxation, was accepted by the Riksdag of 1901, it was generally acknowledged that, in return for the increased taxation, it would only be just to extend the right of taking part in the political life and the legislative work of the country to those of the population who hitherto had been excluded from it. The government eventually laid a proposal for the extension of the franchise before the Riksdag of 1902, the chief feature of which was that the elector should be twenty-five years of age, and that married men over forty years should be entitled to two votes. The Riksdag, however, finally agreed to a proposal by Bishop Billing, a member of the First Chamber, that an address should be presented to the king asking for a full inquiry into the question of extending the franchise for the election of members to the Second Chamber.

In 1897 the Riksdag had received among its members the first socialistic representative in the person of R. H. Brauting, the leader of the Swedish Social Democrats. The Socialists, who had formerly confined their activity to questions affecting the working classes and their wages, took, however, in 1902 an active part in the agitation for the extension of the franchise. Processions of many thousands of workmen were organized, in Stockholm and in other towns of the kingdom, just before the Riksdag began the discussion on the above-mentioned bill of the government, and when the bill was introduced in the chambers a general and well-organized strike took place and continued during the three days the debate on the bill lasted. As this strike was of an exclusively political kind, and was intended to put pressure on the chambers, it was generally disapproved, and failed in its object. The prime minister, Admiral von Otter, resigned shortly after the end of the session, and was succeeded by Boström, the ex-premier, who at the request of the king again assumed office.

Labour Movement.

The relations with Norway during King Oscar's reign had great influence on political life in Sweden, and more than once it seemed as if the union between the two countries was on the point of being wrecked. The dissensions chiefly had their origin in the demand by Norway for separate consuls and foreign ministers, to which reference is made under NORWAY. At last, after vain negotiations and discussions, the Swedish government in 1895 gave notice to Norway that the commercial treaty which till then had existed between the two countries and would lapse in July 1897 would, according to a decision in the Riksdag, cease, and as Norway at the time had raised the customs duties, a considerable diminution in the exports of Sweden to Norway took place. The Swedish minister of foreign affairs, Count Lewenhaupt, who was considered as too friendly disposed towards the Norwegians, resigned, and was replaced by Count Ludvig Douglas, who represented the opinion of the majority in the First Chamber. When, however, the Norwegian Storthing, for the third time, passed a bill for a national or "pure" flag, which King Oscar eventually sanctioned, Count Douglas resigned in his turn and was succeeded by the Swedish minister at Berlin, Lagerheim, who managed to pilot the questions of the union into more quiet waters. He succeeded all the better as the new elections to the Riksdag of 1900 showed clearly that the Swedish people was not inclined to follow the ultra-conservative or so-called "patriotic" party, which resulted in the resignation of the two leaders of that party, Professor Oscar Alin and Count Marschal Patrick Reutersvard as members of the First Chamber. On the other hand, ex-Professor E. Carlson, of the High School of Gothenburg, succeeded in forming a party of Liberals and Radicals to the number of about 90 members, who, besides being in favour of the extension of the franchise, advocated the full equality of Norway with Sweden in the management of foreign affairs. (O. H. D.)

Relations with Norway.

The state of quietude which for some time prevailed with regard to the relations with Norway was not, however, to be of long duration. The question of separate consuls for Norway soon came up again. In 1902 the Swedish government proposed that negotiations in this matter should be opened with the Norwegian government, and that a joint committee, consisting of representatives from both countries, should be appointed to consider the question of a separate consular service without in any way interfering with the existing administration of the diplomatic affairs of the two countries. The result of the negotiations was published in a so-called "communiqué," dated the 24th of March 1903, in which, among other things, it was proposed that the relations of the separate consuls to the joint ministry of foreign affairs and the embassies should be arranged by identical laws, which could not be altered or repealed without the consent of the governments of the two countries. The proposal for these identical laws, which the Norwegian government in May 1904 submitted, did not meet with the approval of the Swedish government. The latter in their reply proposed that the Swedish foreign minister should have such control over the Norwegian consuls as to prevent the latter from exceeding their authority.[1] This proposal, however, the Norwegian government found unacceptable, and explained that, if such control were insisted upon, all further negotiations would be purposeless. They maintained that the Swedish demands were incompatible with the sovereignty of Norway, as the foreign minister was a Swede and the proposed Norwegian consular service, as a Norwegian institution, could not be placed under a foreign authority. A new proposal by the Swedish government was likewise rejected, and in February 1905 the Norwegians broke off the negotiations. Notwithstanding this an agreement did not appear to be out of the question. All efforts to solve the consular question by itself had failed, but it was considered that an attempt might be made to establish separate consuls in combination with a joint administration of diplomatic affairs on a full unionistic basis. Crown Prince Gustaf, who during the illness of King Oscar was appointed regent, took the initiative of renewing the negotiations between the two countries, and on the 5th of April in a combined Swedish and Norwegian council of state made a proposal for a reform both of the administration of diplomatic affairs and of the consular service on the basis of full equality between the two kingdoms, with the express reservation, however, of a joint foreign minister—Swedish or Norwegian—as a condition for the existence of the union. This proposal was approved of by the Swedish Riksdag on the 3rd of May 1905. In order that no obstacles should be placed in the way for renewed negotiations, Mr Boström, the prime minister, resigned and was succeeded by Mr Ramstedt. The proposed negotiations were not, however, renewed.

The Dissolution of the Union with Norway.

On the 23rd of May the Norwegian Storthing passed the government's proposal for the establishment of separate Norwegian consuls, and as King Oscar, who again had resumed the reins of government, made use of his constitutional right to veto the bill, the Norwegian ministry tendered their resignation. The king, however, declared he could not now accept their resignation, whereupon the ministry at a sitting of the Norwegian Storthing on the 7th of June placed their resignation in its hands. The Storthing thereupon unanimously adopted a resolution stating that, as the king had declared himself unable to form a government, the constitutional royal power "ceased to be operative," whereupon the ministers were requested, until further instructions, to exercise the power vested in the king, and as King Oscar thus had ceased to act as "the king of Norway," the union with Sweden was in consequence dissolved.

In Sweden, where they were least of all prepared for the turn things had taken, the action of the Storthing created the greatest surprise and resentment. The king solemnly protested against what had taken place and summoned an extraordinary session of the Riksdag for the 20th of June to consider what measures should be taken with regard to the question of the union, which had arisen suddenly through the revolt of the Norwegians on the 7th of June. The Riksdag declared that it was not opposed to negotiations being entered upon regarding the conditions for the dissolution of the union if the Norwegian Storthing, after a new election, made a proposal for the repeal of the Act of Union between the two countries, or, if a proposal to this effect was made by Norway after the Norwegian people, through a plebiscite, had declared in favour of the dissolution of the union. The Riksdag further resolved that 100 million kroner (about £555,000) should be held in readiness and be available as the Riksdag might decide. On the resignation of the Ramstedt ministry Mr Lundeberg formed a coalition ministry consisting of members of the various parties in the Riksdag, after which the Riksdag was prorogued on the 3rd of August.

The First Extraordinary Riksdag, 1905.

After the plebiscite in Norway on the 13th of August had decided in favour of the dissolution of the union and after the Storthing had requested the Swedish government to co-operate with it for the repeal of the Act of Union, a conference of delegates from both countries was convened at Karlstad on the 31st of August. On the 23rd

The Karlstad Convention.

[1] For further details see NORWAY: *History*.

of September the delegates came to an agreement, the principal points of which were: that such disputes between the two countries which could not be settled by direct diplomatic negotiations, and which did not affect the vital interests of either country, should be referred to the permanent court of arbitration at the Hague, that on either side of the southern frontier a neutral zone of about fifteen kilometres width should be established, and that within eight months the fortifications within the Norwegian part of the zone should be destroyed. Other clauses dealt with the rights of the Laplanders to graze their reindeer alternatively in either country, and with the question of transport of goods across the frontier by rail or other means of communication, so that the traffic should not be hampered by any import or export prohibitions or otherwise.

The Second Extra-ordinary Riksdag.

From the 2nd to the 19th of October the extraordinary Riksdag was again assembled, and eventually approved of the arrangement come to by the delegates at Karlstad with regard to the dissolution of the union as well as the government proposal for the repeal of the Act of Union and the recognition of Norway as an independent state. An alteration in the Swedish flag was also decided upon, by which the mark of union was to be replaced by an azure-blue square. An offer from the Norwegian Storthing to elect a prince of the Swedish royal house as king in Norway was declined by King Oscar, who now on behalf of himself and his successors renounced the right to the Norwegian crown. Mr Lundeberg, who had accepted office only to settle the question of the dissolution of the union, now resigned and was succeeded by a Liberal government with Mr Karl Staaff as prime minister.

The Franchise Question.

The question of the extension of the franchise, which was a burning one, was to be the principal measure of the Staaff government. It brought in a bill for manhood suffrage at elections for the Second Chamber, together with single member constituencies and election on the absolute majority principle. The bill was passed by the Second Chamber on the 15th of May 1906, by 134 to 94 votes, but it was rejected by the First Chamber by 126 to 18. The latter chamber instead passed a bill for manhood suffrage at elections for the Second Chamber, on the condition that the elections for both chambers should take place on the basis of proportional representation. Both chambers thereupon decided to ask the opinion of the king with regard to the simultaneous extension of the franchise to women at elections for the Second Chamber. The government bill having, however, been passed by the Second Chamber, the prime minister proposed to the king that the Riksdag should be dissolved and new elections for the Second Chamber take place in order to hear the opinion of the country, but as the king did not approve of this Mr Staaff and his government resigned.

A Conservative government was then formed on the 29th of May by Mr Lindman, whose principal task was to find a solution of the suffrage question which both chambers could accept. A government bill was introduced, proposing the settlement of the question on the basis of the bill carried by the First Chamber in the Riksdag of the preceding year. A compromise, approved of by the government, was adopted by the First Chamber on the 14th of May 1907 by 110 votes against 29 and in the Second Chamber by 128 against 98. By this act proportional representation was established for both chambers, together with universal manhood suffrage at elections for the Second Chamber, a reduction of the qualifications for eligibility for the First Chamber and a reduction of the electoral term of this chamber from nine to six years, and finally payment of members of the First Chamber, who hitherto had not received any such emolument.

King Oscar II. died on the 9th of December 1907, sincerely regretted by his people, and was succeeded as king of Sweden by his eldest son, Prince Gustaf. During King Oscar's reign many important social reforms were carried out by the legislature, and the country developed in all directions. In the Riksdag of 1884 a new patent law was adopted, the age at which women should be held to attain their majority was fixed at twenty-one years and the barbarous prison punishment of "bread and water" abolished. In order to meet the cost of the new army organization the Riksdag of 1902 increased the revenue by progressive taxation, but only for one year. Bills for the improvement of the social conditions of the people and in the interests of the working classes were also passed. During the five years 1884–1889 a committee was occupied with the question of workmen's insurance, and thrice the government made proposals for its settlement, on the last occasion adopting the principle of invalidity as a common basis for insurance against accidents, illness or old age. The Riksdag, however, delayed coming to a decision, and contented itself by earmarking money for an insurance fund. At last the Riksdag of 1901 accepted a Bill for insurance against accidents which also extended to agricultural labourers, in connexion with the establishment of a state institution for insurance. The bill for protection against accidents, as well as for the limitation of working hours for women and children, was passed, together with one for the appointment of special factory inspectors. When in 1897 King Oscar celebrated his jubilee of twenty-five years as king, the exhibition which had been organized in Stockholm offered a convincing proof of the progress the country had made in every direction.

SWEDISH LITERATURE

Swedish literature, as distinguished from compositions in the common *norraena tunga* of old Scandinavia, cannot be said to exist earlier than the 13th century. Nor until the period of the Reformation was its development in any degree rapid or copious. The oldest form in which Swedish exists as a written language (see SCANDINAVIAN LANGUAGE) is the series of manuscripts known as *Landskapslagarne*, or "The Common Laws." These are supposed to be the relics of a still earlier age, and it is hardly believed that we even possess the first that was put down in writing. The most important and the most ancient of these codes is the "Elder West Göta Law," reduced to its present form by the law-man Eskil about 1230. Another of great interest is Magnus Eriksson's "General Common Law," which was written in 1347. These ancient codes have been collected and edited by the learned jurist, K. J. Schlyter (1795–1888) as *Corpus juris Sveo-Gotorum antiqui* (4 vols., 1827–1869). The chief ornament of medieval Swedish literature is *Um styrilse kununga ok höfdinga* ("On the Conduct of Kings and Princes"), first printed by command of Gustavus II. Adolphus, in 1634. The writer is not known; it has been conjecturally dated 1325. It is a handbook of moral and political teaching, expressed in terse and vigorous language. St Bridget, or Birgitta (1303–1373), an historical figure of extraordinary interest, has left her name attached to several important religious works, in particular to a collection of *Uppenbarelser* ("Revelations"), in which her visions and ecstatic meditations are recorded, and a version, the first into Swedish, of the five books of Moses. This latter was undertaken, at her desire, by her father-confessor Mattias (d. 1350), a priest at Linköping. The translation of the Bible was continued a century later by a monk named Johannes Budde (d. 1484).

In verse the earliest Swedish productions were probably the folk-song.[1] The age of these, however, has been commonly exaggerated. It is doubtful whether any still exist which are as old, in their present form, as the 13th century. The bulk are now attributed to the 15th, and many are doubtless much later still. The last, such as "Axel och Valborg," "Liten Karin," "Kämpen Grimborg," and "Habor och Signild," deal with the adventures of romantic medieval romance. Almost the only positive clue we hold to the date of these poems is the fact that one of the most characteristic of them, "Engelbrekt," was written by Thomas, bishop of Strengnäs, who died in 1443. Thomas, who left other poetical pieces, is usually called the first Swedish poet. There are three rhyming chronicles in medieval Swedish, all anonymous. The earliest, *Erikskronikan*,[2] is attributed to 1320; the romance of Karl Magnus, *Nya Karlskrönikan*, describing the period between 1387 and 1452, which is sometimes added to the earlier work, dates from the middle of the 15th century; and the third, *Sturekrönikorna*, was probably written about 1500. The collection of rhymed romances which bears the name of *Queen Euphemia's Songs* must have been written before the death of the Norwegian queen in 1312. They are versions of three medieval stories taken from French and German sources, and dealt with the Chevalier au lion, of Chrestien de Troyes, with Duke Frederick of Normandy, and with Flores and Blancheflor. They possess very slight poetic merit in their Swedish form. A little later the romance of *King Alexander*[3] was translated by, or at the command of, Bo Jonsson Grip; this is more meritorious. Bishop Thomas, who died in 1443, wrote many political songs; and a number of narrative poems date from the close of the century. A brilliant and pathetic relic of the close of the medieval period exists in the *Love Letters* addressed in 1498 by Ingrid Persdotter, a nun of Vadstena, to the young knight Axel Nilsson. The first book printed in the Swedish language appeared in 1495.

The 16th century added but little to Swedish literature, and that little is mostly connected with the newly-founded university of Upsala. The Renaissance scarcely made itself felt in Scandinavia, and even the Reformation failed to waken the genius of the country. Psalms and didactic spiritual poems were the main products of Swedish letters in the 16th century. Two writers, the brothers Petri, sons of a smith at Orebro, take an easy prominence in so barren a period. Olaus Petri (1493–1552) and Laurentius Petri (1499–1573) were Carmelite monks who adopted the Lutheran doctrine while studying at Wittenberg, and came back to Sweden in 1518 as the apostles of the new faith. Olaus, who is one of the noblest figures in Swedish annals, was of the executive rather than the meditative class. He became chancellor to Gustavus Vasa, but his reforming zeal soon brought him into disgrace, and in 1540 he was condemned to death. Two years later he was pardoned, and allowed to resume his preaching in Stockholm. He found time, however, to write a *Swedish Chronicle*, which is the earliest prose history of Sweden, a mystery-play, *Tobiae comedia*, which is the first Swedish drama, and three psalm-books, the best known being published in 1530 under the title of *Några gudhelige vijsor* ("Certain Divine Songs"). His *Chronicle* was based on a number of sources, in the treatment of which he showed a discrimination which makes the work still useful. Laurentius Petri, who was a man of calmer temperament, was archbishop of all Sweden, and edited or superintended the translation of the

The Petri.

[2] See Cederschiöld, *Om Erikskrönikan* (1899).

[3] Editions of these chronicles and romances have been issued by the "Svenska Fornskrift Sällskapet" (Stockholm): *Ivan Lejonriddaren* (ed. Stephens), *Hertig Fredrik of Normandie* (ed. Ahlstrand) *Flores och Blancheflor* (ed. G. E. Klemming), Alexander (ed. Klemming), Carl Magnus (ed. Klemming, in *Prosadikter från medeltiden*).

Bible published at Upsala in 1540. He also wrote many psalms. Laurentius Andreae, 1552, had previously prepared a translation of the New Testament, which appeared in 1526. He was a polemical writer of prominence on the side of the Reformers. Finally, Petrus Niger (Peder Svart), bishop of Vesterås (d. 1562), wrote a chronicle of the life of Gustavus I. up to 1533, in excellent prose. The same writer left unpublished a history of the bishops of Vesterås, his predecessors. The latter half of the 16th century is a blank in Swedish literature.

Buraeus.

With the accession of Charles IX., and the consequent development of Swedish greatness, literature began to assert itself in more vigorous forms. The long life of the royal librarian, Johannes Bure or Buraeus (1568–1652), formed a link between the age of the Petri and that of Stjernhjelm. Buraeus studied all the sciences then known to mankind, and confounded them all in a sort of Rabbinical cultus of his own invention, a universal philosophy in a multitude of unreadable volumes.[4] But he was a patient antiquary, and advanced the knowledge of ancient Scandinavian mythology and language very considerably. He awakened curiosity and roused a public sympathy with letters; nor was it without significance that two of the greatest Swedes of the century, Gustavus Adolphus and the poet Stjernhjelm, were his pupils. The reign of Charles IX. saw the rise of secular drama in Sweden. The first comedy was the *Tisbe* of Magnus Olai Asteropherus (d. 1647), a coarse but witty piece on the story of Pyramus and Thisbe, acted by the schoolboys of the college of Arboga in 1610. This play is the *Ralph Roister Doister* of Swedish literature. A greater dramatist was Johannes Messenius (1579–1636), who was the son of a miller near Vadstena and had been carefully educated abroad by the Jesuits. Being discovered plotting against the government during the absence of Gustavus in Russia, he was condemned to imprisonment for life—that is, for twenty years. Before this disaster he had been professor of jurisprudence in Upsala, where his first historical comedy *Disa* was performed in 1611 and the tragedy of *Signill* in 1612. The design of Messenius was to write the history of his country in fifty plays; he completed and produced six. These dramas[5] are not particularly well arranged, but they form a little body of theatrical literature of singular interest and value. Messenius was a genuine poet; the lyrics he introduces have something of the charm of the old ballads. He wrote abundantly in prison; his magnum opus was a history of Sweden in Latin, but he has also left, in Swedish, two important rhyme-chronicles. Messenius was imitated by a little crowd of playwrights. Nikolaus Holgeri Catonius (d. 1655) wrote a fine tragedy on the Trojan War, *Troijenborgh*, in which he excelled Messenius as a dramatist. Andreas Prytz, who died in 1655 as bishop of Linköping, produced several religious chronicle plays from Swedish history. Jacobus Rondeletius (d. 1662) wrote a curious "Christian tragi-comedy" of *Judas redivivus*, which contains some amusing scenes from daily Swedish life. Another good play was an anonymous *Holofernes and Judith* (edited at Upsala, 1895, by O. Sylwan). These plays were all acted by schoolboys and university youths, and when they went out of fashion among these classes the drama in Sweden almost entirely ceased to exist. Two historians of the reign of Charles IX., Erik Göransson Tegel (d. 1636) and Aegidius Girs (d. 1639), deserve mention. The chancellor Magnus Gabriel de la Gardie (1622–1686) did much to promote the study of Swedish antiquities. He founded the College of Antiquities at Upsala in 1667, and bought back the Gothic *Codex argenteus* which he presented to the university library.

Stjernhjelm.

The reign of Gustavus Adolphus was adorned by one great writer, the most considerable in all the early history of Sweden. The title of "the Father of Swedish poetry" has been universally awarded to Göran Lilja, better known by his adopted name of Georg Stjernhjelm (*q.v.*; 1598–1672). Stjernhjelm was a man of almost universal attainment, but it is mainly in verse that he has left his stamp upon

[4] Selections from his writings were edited by G. E. Klemming, (Upsala, 1883–1885).

[5] Edited for a learned society (Upsala, 1886, &c.) by H. Schück.

the literature of his country. He found the language rough and halting, and he moulded it into perfect smoothness and elasticity. His master, Buraeus, had written a few Swedish hexameters by way of experiment. Stjernhjelm took the form and made it national.

The claim of Stjernhjelm to be the first Swedish poet may be contested by a younger man, but a slightly earlier writer, Gustaf Rosenhane (1619–1684), who was a reformer on quite other lines. If Stjernhjelm studied Opitz, Rosenhane took the French poets of the Renaissance for his models, and in 1650 wrote a cycle of one hundred sonnets, the earliest in the language; these were published under the title *Venerid* in 1680. Rosenhane printed in 1658 a "Complaint of the Swedish Language" in thirteen hundred rattling rhyming lines, and in 1682 a collection of eighty songs. He was a metrist of the artistic order, skilful, learned and unimpassioned. His zeal for the improvement of the literature of his country was beyond question. Most of the young poets, however, followed Stjernhjelm rather than Rosenhane. As personal friends and pupils of the former, the brothers Columbus deserve special attention. They were sons of a musician and poet, Jonas Columbus (1586–1663). Each wrote copiously in verse, but Johan (1640–1684), who was professor of poetry at Upsala, almost entirely in Latin, while Samuel (1642–1679), especially in his *Odae sveticae*, showed himself an apt and fervid imitator of the Swedish hexameters of Stjernhjelm, to whom he was at one time secretary, and whose *Hercules* he dramatized. His works were included by P. Hanselli in vol. ii. of *Samlade vitterhets arbeten*, &c.

Rosenhane.

Of a rhyming family of Hjärne, it is enough to mention one member, Urban Hjärne (1641–1724), who introduced the new form of classical tragedy from France, in a species of transition from the masques of Stjernhjelm to the later regular rhymed dramas. His best play was a *Rosimunda*. Lars Johansson (1642–1674), who called himself "Lucidor the Unfortunate," has been the subject of a whole tissue of romance, most of which is fabulous. It is true, however, that he was stabbed, like Marlowe, in a midnight brawl at a tavern. His poems were posthumously collected as *Flowers of Helicon, Plucked and Distributed on various occasions by Lucidor the Unfortunate*. Stripped of the myth which had attracted so much attention to his name, Lucidor proves to be an occasional rhymester of a very low order. Haquin Spegel (1645–1714), the famous archbishop of Upsala, wrote a long didactic epic in alexandrines, *God's Labour and Rest*, with an introductory ode to the Deity in rhymed hexameters. He was also a good writer of hymns. Another ecclesiastic, the bishop of Skara, Jesper Svedberg (1653–1735), wrote sacred verses, but is better remembered as the father of Swedenborg. Peter Lagerlöf (1648–1699) cultivated a pastoral vein in his ingenious lyrics *Elisandra* and *Lycillis*; he was professor of poetry, that is to say, of the art of writing Latin verses, at Upsala. Olof Wexionius (1656–1690?) published his *Sinne-Afvel*, a collection of graceful miscellaneous pieces, in 1684, in an edition of only 100 copies. Its existence was presently forgotten, and the name of Wexionius had dropped out of the history of literature, when Hanselli recovered a copy and reprinted its contents in 1863.

Dahlstjerna.

We have hitherto considered only the followers of Stjernhjelm; we have now to speak of an important writer who followed in the footsteps of Rosenhane. Gunno Eurelius, afterwards ennobled with the name of Dahlstjerna (*q.v.*; 1661–1709), early showed an interest in the poetry of Italy. In 1690 he translated Guarini's *Pastor Fido*, and in or just after 1697 published, in a folio volume without a date, his *Kunga-Skald*, the first original poem in *ottava rima* produced in Swedish. This is a bombastic and vainglorious epic in honour of Charles XI., whom Eurelius adored; it is not, however, without great merits, richness of language, flowing metre, and the breadth of a genuine poetic enthusiasm. He published a little collection of lamentable sonnets when his great master died. Johan Paulinus Liljenstedt (1655–1732), a Finn, was a graceful imitator of Ronsard and Guarini. Johan Runius (1679–1713), called the "Prince of Poets," published a collection entitled *Dudaim*, in which there is nothing to praise, and with him the generation of the 17th century closes. Talent had been shown by certain individuals, but no healthy school of Swedish poetry had been founded, and the latest imitators of Stjernhjelm had lost every vestige of taste and independence.

Rudbeck.

In prose the 17th century produced but little of importance in Sweden. Gustavus Adolphus (1594–1632) was the most polished writer of its earlier half, and his speeches take an important place in the development of the language. The most original mind of the next age was Olof Rudbeck (1630–1702), the famous author of *Atland eller Manhem*. He spent nearly all his life in Upsala, building anatomical laboratories, conducting musical concerts, laying out botanical gardens, arranging medical lecture rooms—in a word, expending ceaseless energy on the practical improvement of the university. He was a genius in all the known branches of learning; at twenty-three his physiological discoveries had made him famous throughout Europe. His *Atland* (or *Atlantika*) appeared in four folio volumes, in Latin and Swedish, in 1675–1698; it was an attempt to summon all the authority of the past, all the sages of Greece and the bards of Iceland, to prove the inherent and indisputable greatness of the Swedish nation, in which the fabulous Atlantis had been at last discovered. It was the literary expression of the majesty of Charles XI., and of his autocratical dreams for the destiny of Sweden. From another point of view it is a monstrous hoard or cairn of rough-hewn antiquarian learning, now often praised, sometimes quoted from, and never read. Olof Verelius (1618–1682) had led the way for Rudbeck, by his translations of Icelandic sagas, a work which was carried on with greater intelligence by Johan Peringskjöld (1654–1720), the editor of the *Heimskringla* (1697), and J. Hadorph (1630–1693). The French philosopher Descartes, who died at Christina's court at Stockholm in 1650, found his chief, though posthumous, disciple in Andreas Rydelius (1671–1738), bishop of Lund, who was the master of Dalin, and thus connects us with the next epoch. His chief work, *Nödiga förnuftsöfningar . . .* (5 vols.) appeared in 1718. Charles XII., under whose special patronage Rydelius wrote, was himself a metaphysician and physiologist of merit.

A much more brilliant period followed the death of Charles XII. The influence of France and England took the place of that of Germany and Italy. The taste of Louis XIV., tempered by the study of Addison and Pope, gave its tone to the academical court of Queen Louise Ulrica, who founded in 1758 the academy of literature, which developed later into the academy of literature, history and antiquities.

Dalin.

Sweden became completely a slave to the periwigs of literature, to the unities and graces of classical France. Nevertheless this was a period of great intellectual stimulus and activity, and Swedish literature took a solid shape for the first time. This Augustan period in Sweden closed somewhat abruptly about 1765. Two writers in verse connect it with the school of the preceding century. Jacob Frese (1692?–1728?), a Finn, whose poems were published in 1726, was an elegiacal writer of much grace, who foreshadowed the idyllic manner of Creutz. Atterbom pronounces Frese the best Swedish poet between Stjernhjelm and Dalin. Samuel von Triewald (1688–1743) played a very imperfect Dryden to Dalin's Pope. He was the first Swedish satirist, and introduced Boileau to his countrymen. His *Satire upon our Stupid Poets* may still be read with entertainment.[1] Both in verse and prose Olof von Dalin (*q.v.*; 1708–1763) takes a higher place than any writer since Stjernhjelm. He was inspired by the study of his great English contemporaries. His *Swedish Argus* (1733–1734) was modelled on Addison's *Spectator*, his *Thoughts about Critics* (1736) on Pope's *Essay on Criticism*, his *Tale of a Horse* on Swift's *Tale of a Tub*. Dalin's style,

[1] The works of the chief writers between Sternhjelm and Dalin were edited by P. Hanselli (Upsala, 1856, &c.) as *Samlade vitterhets-arbeten-af svenska författare*.

whether in prose or verse, was of a finished elegance. As a prose writer Dalin is chiefly memorable for his *History of the Swedish Kingdom* (4 vols., 1746–1762). His great epic, *Swedish Freedom* (1742) was written in alexandrines of far greater smoothness and vigour than had previously been attempted. When in 1737 the new Royal Swedish Theatre was opened, Dalin led the way to a new school of dramatists with his *Brynhilda*, a regular tragedy in the style of Crébillon *père*. In his comedy of *The Envious Man* he introduced the manner of Molière, or more properly that of Holberg. His songs, his satires, his occasional pieces, without displaying any real originality, show Dalin's tact and skill as a workman with the pen. He stole from England and France, but with the plagiarism of a man of genius; and his multifarious labours raised Sweden to a level with the other literary countries of Europe. They formed a basis upon which more national and more scrupulous writers could build their various structures. A foreign critic, especially an English one, will never be able to give Dalin so much credit as the Swedes do; but he was certainly an unsurpassable master of *pastiche*. His works were collected in 6 vols., 1767.

Fru Nordenflycht.

The only poet of importance who contested the laurels of Dalin was a woman. Hedvig Charlotta Nordenflycht (1718–1763) was the centre of a society which took the name of *Tankebyggare Orden* and ventured to rival that which Queen Louise Ulrica created and Dalin adorned. Both groups were classical in taste, both worshipped the new lights in England and France. Fru Nordenflycht wrote with facility and grace; her collection of lyrics, *The Sorrowing Turtledove* (1743), in spite of its affectation, enjoyed and merited a great success; it was the expression of a deep and genuine sorrow—the death of her husband after a very brief and happy married life. It was in 1744 that she settled in Stockholm and opened her famous literary salon. She was called "The Swedish Sappho," and scandal has been needlessly busy in giving point to the allusion. It was to Fru Nordenflycht's credit that she discovered and encouraged the talent of two very distinguished poets younger than herself, Creutz and Gyllenborg, who published volumes of poetry in collaboration.

Creutz.

Count Gustaf Philip Creutz (*q.v.*; 1731–1785) was a Finlander who achieved an extraordinary success with his idyllic poems, and in particular with the beautiful pastoral of *Atis och Camilla*, long the most popular of all Swedish poems. His friend Count Gustaf Fredrik

Gyllenborg.

Gyllenborg (1731–1808) was a less accomplished poet, less delicate and touching, more rhetorical and artificial. His epic *Tåget öfver Bält* ("The Expedition across the Belt") (1785) is an imitation, in twelve books, of Voltaire's *Henriade*, and deals with the prowess of Charles X. He wrote fables, allegories, satires, and a successful comedy of manners, *The Swedish Fop*. He outlived his chief contemporaries so long that the new generation addressed him as "Father Gyllenborg." Anders Odel (1718–1773) wrote in 1739 the famous "Song of Malcolm Sinclair," the *Sinclairsvisa*. The writers of verse in this period were also exceedingly numerous.

Prose Writers.

In prose, as was to be expected, the first half of the 18th century was rich in Sweden as elsewhere. The first Swedish novelist was Jakob Henrik Mörk (1714–1763). His romances have some likeness to those of Richardson; they are moral, long-winded, and slow in evolution, but written in an exquisite style, and with much knowledge of human nature. *Adalrik och Göthilda*, which went on appearing from 1742 to 1745, is the best known; it was followed, between 1748 and 1758, by *Thecla*. Jakob Wallenberg (1746–1778) described a voyage he took to the East Indies and China under the very odd title of *Min son på galejan* ("My Son at the Galleys"), a work full of humour and originality.

Johan Ihre (1707–1780), a professor at Upsala, edited the *Codex argenteus* of Ulfilas, and produced the valuable *Svenskt Dialect Lexicon* (1766) based on an earlier learned work, the *Dialectologia* of Archbishop Erik Benzelius (d. 1743). He settled for some time at Oxford. Ihre's masterpiece is the *Glossarium sueogothicum* (1769), a historical dictionary with many valuable examples from the ancient monuments of the language. In doing this he was assisted by the labours of two other grammarians, Sven Hof (d. 1786) and Abraham Sahlstedt (d. 1776). The chief historians were Sven Lagerbring (1707–1787), author of a still valuable history of Sweden down to 1457 (*Svea Rikes historia*, 4 vols., 1769–1783); Olof Celsius (1716–1794), bishop of Lund, who wrote histories of Gustavus I. (1746–1753) and of Eric XIV. (1774); and Karl Gustaf Tessin (1695–1770) who wrote on politics and on aesthetics. Tessin's *Old Man's Letters to a young Prince* were addressed to his pupil, afterwards Gustavus III. Count Anders Johan von Höpken (1712–1789), the friend of Louise Ulrica, was a master of rhetorical compliment in addresses and funeral orations.

In spite of all the encouragement of the court, drama did not flourish in Sweden. Among the tragic writers of the age we may mention Dalin, Gyllenborg, and Erik Wrangel (1686–1765). In comedy Reinhold Gustaf Modée (d. 1752) wrote three good plays in rivalry of Holberg.

In science Linnaeus, or Karl von Linné (1707–1778), was the name of greatest genius in the whole century; but he wrote almost entirely in Latin. The two great Swedish chemists, Torbern Olof Bergman (1735–1784) and Karl Vilhelm Scheele (1742–1786), flourished at this time. In pathology a great name was left by Nils Rosén von Rosenstein (1706–1773), in navigation by Admiral Fredrik Henrik af Chapman (d. 1808), in philology by Karl Aurivillius (d. 1786). But these and other distinguished savants whose names might be enumerated scarcely belong to the history of Swedish literature. The same may be said about that marvellous and many-sided genius, Emanuel Swedenborg (1688–1772), who, though the son of a Swedish poet, preferred to prophesy to the world in Latin.

The Gustavian period.

What is called the Gustavian period is supposed to commence with the reign of Gustavus III. in 1771 and to close with the abdication of Gustavus IV. in 1809. This period of less than forty years was particularly rich in literary talent, and the taste of the people in literary matters widened to a remarkable extent. Journalism began to develop; the Swedish Academy was founded; the drama first learned to flourish in Stockholm; and literature began to take a characteristically national shape. This fruitful period naturally divides itself into two divisions, equivalent to the reigns of the two kings. The royal personages of Sweden have commonly been protectors of literature; they have strangely often been able men of letters themselves. Gustavus III. (1746–1792), the founder of the Swedish Academy and of the Swedish theatre, was himself a playwright of no mean ability. One of his prose dramas, *Siri Brahe och Johan Gyllenstjerna*, held the stage for many years. But his best work was his national drama of *Gustaf Vasa* (1783), written by the king in prose, and afterwards versified by Kellgren. In 1773 the king opened the national theatre in Stockholm, and on that occasion an opera of *Thetis och Pelée* was performed, written by himself. In 1786 Gustavus created the Swedish Academy, on the lines of the French Academy, but with eighteen members instead of forty. The first list of immortals, which included the survivors of a previous age and such young celebrities as Kellgren and Leopold, embraced all that was most brilliant in the best society of Stockholm; the king himself presided, and won the first prize for an oration. The works of Gustavus III. in six volumes were printed at Stockholm in 1802–1806.

Bellman.

The principal writers of the reign of Gustavus III. bear the name of the academical school. But Karl Mikael Bellman (*q.v.*; 1740–1795), the most original and one of the most able of all Swedish writers, an improvisatore of the first order, had nothing academical in his composition. The riot of his dithyrambic hymns sounded a strange note of nature amid the conventional music of the Gustavians. Of the academical poets Johan Gabriel Oxenstjerna (1750–1818), the nephew of Gyllenborg, was a descriptive idyllist of grace.

He translated *Paradise Lost.* A writer of far more power and versatility was Johan Henrik Kellgren (*q.v.*; 1751–1795), the leader of taste in his time.

Kellgren.

He was the first writer of the end of the century in Sweden, and the second undoubtedly was Karl Gustaf af Leopold[1] (1756–1829), "the blind seer Tiresias-Leopold," who lived on to represent the old school in the midst of romantic times.

Leopold.

Leopold attracted the notice of Gustavus III. by a volume of *Erotic Odes* (1785). The king gave him a pension and rooms in the palace, admitting him on intimate terms. He was not equal to Kellgren in general poetical ability, but he is great in didactic and satiric writing. He wrote a satire, the *Enebomiad,* against a certain luckless Per Enebom, and a classic tragedy of *Virginia.* Gudmund Göran Adlerbeth (1751–1818) made translations from the classics and from the Norse, and was the author of a successful tragic opera, *Cora och Alonzo* (1782). Anna Maria Lenngren (1754–1817) was a very popular sentimental writer of graceful domestic verse, chiefly between 1792 and 1798. She was less French and more national than most of her contemporaries; she is a Swedish Mrs Hemans. Much of her work appeared anonymously, and was generally attributed to her contemporaries Kellgren and Leopold.

Two writers of the academic period, besides Bellman, and a generation later than he, kept apart, and served to lead up to the romantic revival.

Lidner.

Bengt Lidner (1759–1793), a melancholy and professedly elegiacal writer, had analogies with Novalis. He interrupted his studies at the university by a voyage to the East Indies, and only returned to Stockholm after many adventures. In spite of the patronage of Gustavus III. he continued to lead a disordered, wandering life, and died in poverty. A short narrative poem, *The Death of the Countess Spastara* (1783), has retained its popularity. Lidner was a genuine poet, and his lack of durable success must be set down to faults of character, not to lack of inspiration. His poems appeared in 1788. Thomas Thorild (1759–1808) was a much stronger nature, and led the revolt against prevailing taste with far more vigour.

Thorild.

But he is an irregular and inartistic versifier, and it is mainly as a prose writer, and especially as a very original and courageous critic, that he is now mainly remembered. He settled in Germany and died as a professor in Greifswald. Karl August Ehrensvärd (1745–1800) may be mentioned here as a critic whose aims somewhat resembled those of Thorild. The creation of the Academy led to a great production of aesthetic and philosophical writing. Among critics of taste may be mentioned Nils Rosén von Rosenstein (1752–1824); the rhetorical bishop of Linköping, Magnus Lehnberg (1758–1808); and Count Georg Adlersparre (1760–1809). Rosén von Rosenstein embraced the principles of the encyclopaedists while he was attached to the Swedish embassy in Paris. On his return to Sweden he became tutor to the crown prince, and held in succession a number of important offices. As the first secretary of the Swedish Academy he exercised great influence over Swedish literature and thought. His prose writings, which include prefaces to the works of Kellgren and Lidner, and an eloquent argument against Rousseau's theory of the injurious influence of art and letters, rank with the best of the period. Kellgren and Leopold were both of them important prose writers.

The excellent lyrical poet Frans Mikael Franzén (*q.v.*; 1772–1847) and a belated academician Johan David Valerius (1776–1852), fill up the space between the Gustavian period and the domination of romantic ideas from Germany.

Hammarsköld.

It was Lorenzo Hammarsköld (1785–1827) who in 1803 introduced the views of Tieck and Schelling by founding the society in Upsala called "Vitterhetens Vänner," and by numerous critical essays. His chief work was *Svenska vitterheten* (1818, &c.) a history of Swedish literature. Hammarsköld's society was succeeded in 1807 by the famous "Aurora förbundet," founded by two youths of genius, Per Daniel Amadeus Atterbom (1790–1855) and Vilhelm Fredrik Palmblad (1788–1852).

Atterbom.

These young men had at first to endure bitter opposition and ridicule from the academic writers then in power, but they supported this with cheerfulness, and answered back in their magazines *Polyfem* and *Fosforos* (1810–1813). They were named "Fosforisterna" ("Phosphorists") from the latter. Another principal member of the school was Karl Frederik Dahlgren (*q.v.*; 1791–1844), a humorist who owed much to the example of Bellman. Fru Julia Nyberg (1785–1854), under the title of Euphrosyne, was their tenth Muse, and wrote agreeable lyrics. Among the Phosphorists Atterbom was the man of most genius. On the side of the Academy they were vigorously attacked by Per Adam Wallmark (1777–1858), to whom they replied in a satire which was the joint work of several of the romanticists, *Markall's Sleepless Nights.* One of the innovators, Atterbom, eventually forced the doors of the Academy itself.

In 1811 certain young men in Stockholm founded a society for the elevation of society by means of the study of Scandinavian antiquity.

Gothic Society.

This was the Gothic Society, which began to issue the magazine called *Iduna* as its organ. Of its patriotic editors the most prominent was Erik Gustaf Geijer (*q.v.*; 1783–1847), but he was presently joined by a young man slightly older than himself, Esaias Tegnér (*q.v.*; 1782–1846), afterwards bishop of Vexiö, the greatest of Swedish writers.

Geijer.

Tegnér.

Even more enthusiastic than either in pushing to its last extreme the worship of ancient myths and manners was Per Henrik Ling (1776–1839), now better remembered as the father of gymnastic science than as a poet. The Gothic Society eventually included certain younger men than these—Arvid August Afzelius (1785–1871), the first editor of the Swedish folk-songs; Gustaf Vilhelm Gumaelius (1789–1877), who has been somewhat pretentiously styled "The Swedish Walter Scott," author of the historical novel of *Tord Bonde*; Baron Bernhard von Beskow (*q.v.*; 1796–1868), lyrist and dramatist; and Karl August Nicander (1799–1839), a lyric poet who approached the Phosphorists in manner. The two great lights of the Gothic school are Geijer, mainly in prose, and Tegnér, in his splendid and copious verse. Johan Olof Wallin (1779–1839) may be mentioned in the same category, although he is really distinct from all the schools.

Wallin.

He was archbishop of Upsala, and in 1819 he published the national hymn-book of Sweden; of the hymns in this collection, 126 are written by Wallin himself.

From 1810 to 1840 was the blossoming-time in Swedish poetry, and there were several writers of distinguished merit who could not be included in either of the groups enumerated above.

Stagnelius.

Second only to Tegnér in genius, the brief life and mysterious death of Erik Johan Stagnelius (1793–1823) have given a romantic interest to all that is connected with his name. His first publication was the epic of *Vladimir the Great* (1817); to this succeeded the romantic poem *Blanda.* His singular dramas, *The Bacchantes* (1822), *Sigurd Ring,* which was posthumous, and *The Martyrs* (1821), are esteemed by many critics to be his most original productions. His mystical lyrics, entitled *Liljor i Saron* ("Lilies in Sharon"; 1820), and his sonnets, which are the best in Swedish, may be recommended as among the most delicate products of the Scandinavian mind. Stagnelius has been compared, and not improperly, to Shelley.[2] Erik Sjöberg, who called himself "Vitalis" (1794–1828), was another gifted poet whose career was short and wretched.

Sjöberg.

A volume of his poems appeared in 1820; they are few in number and all brief. His work divides itself into two classes—the one profoundly melancholy, the other witty or boisterous. Two humorous poets of the same period who deserve mention are Johan Anders Wadman (1777–1837), an improvisatore of the same class as Bellman, and Christian Erik Fahlcrantz (*q.v.*; 1790–1866).

Among the poets who have been mentioned above, the

[1] His works were edited by C. R. Nyblom (2 vols., 1873).

[2] His collected works were edited by C. Eichhorn (2 vols., Stockholm, 1867–1868). Several of Stagnelius' poems were translated into English by Edmund Gosse 1886).

majority distinguished themselves also in prose. But the period was not one in which Swedish prose shone with any special lustre. The first prosaist of the time was, without question, the novelist, Karl Jonas Ludvig Almqvist, (*q.v.*; 1793–1866), around whose extraordinary personal character and career a mythical romance has already collected (see ALMQVIST). He was encyclopaedic in his range, although his stories preserve most charm; on whatever subject he wrote his style was always exquisite. Fredrik Cederborgh (1784–1835) revived the comic novel in his *Uno von Trasenberg* and *Ottar Tralling*. The historical novels of Gumaelius have already been alluded to. Swedish history supplied themes for the romances of Count Per Georg Sparre (1790–1871) and of Gustaf Henrik Mellin (1803–1876). But all these writers sink before the sustained popularity of the Finnish poet Fredrika Bremer (*q.v.*; 1801–1865), whose stories reached farther into the distant provinces of the world of letters than the writings of any other Swede except Tegnér. She was preceded by Sofia Margareta Zelow, afterwards Baroness von Knorring (1797–1848), who wrote a long series of aristocratic novels.

Almqvist.

Fredrika Bremer.

A polemical writer of great talent was Magnus Jakob Crusenstople (1795–1865), of whose work it has been said that "it is not history and it is not fiction, but something brilliant between the one and the other." As an historian of Swedish literature Per Wieselgren (1800–1877) composed a valuable work, and made other valuable contributions to history and bibliography. In history we meet again with the great name of Geijer, with that of Jonas Hallenberg (1748–1834), and with that of Anders Magnus Strinnholm (1786–1862), whose labours in the field of Swedish history were extremely valuable. Geijer and Strinnholm prepared the way for the most popular of all Swedish historians, Anders Fryxell (1795–1881), whose famous *Berättelser ur svenska historien* appeared in parts during a space of nearly sixty years, and awakened a great interest in Swedish history and legend.

In 1850 the first poet of Sweden, without a rival, was Johan Ludvig Runeberg (*q.v.*; 1804–1877), whose reputation rivals that of Tegnér. Bernhard Elis Malmström (1816–1865), who was a professor of aesthetics at the university of Upsala, was the author of many important books on artistic and literary history, notably a monograph on Franzén. His poetry, although small in volume, gives him a place beside Runeberg. A volume of elegies, *Angelika* (1840), established his fame, and two volumes of poems published in 1845 and 1847 contain a number of ballads, romances and lyrics which keep their hold on Swedish literature. He was an exact and discriminating critic, and inclined to severity in his strictures on the romanticists. The other leading verse-writers were Karl Vilhelm Böttiger (1807–1878), the son-in-law and biographer of Tegnér, who, in addition to his lyrical poetry, chiefly of the sentimental kind, wrote an admirable series of monographs on Swedish men of letters; Johan Börjesson (1790–1866), the last of the Phosphorists, author of various romantic dramas; Vilhelm August Detlof von Braun (1813–1860), a humorous lyrist; "Talis Qualis," whose real name was Karl Vilhelm August Strandberg (1818–1877); Oscar Patrick Sturzen-Becker (1811–1869), better known as "Orvar Odd," a lyrical poet who was also the author of a series of amusing sketches of everyday life; and August Teodor Blanche (1811–1868), the popular dramatist. Blanche produced a number of farces and comedies which were announced as pictures from real life. His pieces abound in comic situations, and some of them, *Magister Bläckstadius* (1844), *Rika Morbror* (1845), *En tragedi i Vimmerby* (1848) and others, maintain their reputation. Fredrik August Dahlgren (1816–1895) gained a great reputation as a dramatist by his national opera, *Vermländingarne* (1846). He is also the author of translations from Shakespeare and Calderon, and of considerable historical works. Other notable plays of the period were the *En Komedi* of J. C. Jolin (1818–1884) and the *Bröllopet på Ulfåsa* (1865) of Frans Hedberg (1828–1908). But Runeberg is the only great poetic name of this period.

Runeberg.

In prose there was not even a Runeberg. The best novelist of the time was Emilie Flygare-Carlén (1807–1892). The art was sustained by Karl Anton Wetterbergh (1804–1889), who called himself "Onkel Adam," by August Blanche the dramatist, and by Marie Sofie Schwartz (1819–1892). Fru Schwartz (née Birat) wrote novels demonstrating the rights of the poor against the rich, of which *The Man of Birth and the Woman of the People* (Eng. trans., 1868) is a good example. Lars Johan Hierta (1801–1872) was the leading journalist, Johan Henrik Thomander, bishop of Lund (1798–1865), the greatest orator, Matthias Alexander Castrén (1813–1852) a prominent man of science, and Karl Gustaf af Forsell (1783–1848), the principal statistician of this not very brilliant period. Elias Lönnrot (*q.v.*; 1802–1884) is distinguished as the Finnish professor who discovered and edited the *Kalevala*.

The most popular poet at the close of the 19th century was the patriotic Finn, Zakris Topelius (*q.v.*; 1818–1898). Of less importance were Karl Herman Sätherberg (1812–1897), a romantic poet who was also a practising physician of distinction; the elegiac poet Johan Nybom (1815–1889); and the poet, novelist, and dramatist Frans Hedberg (d. 1908), who in his old age made many concessions to the modern taste. The posthumous poems of the bishop of Strängnäs, Adam Teodor Strömberg (1820–1889), were collected by Wirsén, and created some sensation. A typical academician was the poet, antiquary and connoisseur, Nils Fredrik Sander (1828–1900). The improvisator of *Gluntarne*, Gunnar Wennerberg (*q.v.*; 1817–1901) survived as a romantic figure of the past. Still older was the poetess Wilhelmina Nordström (1815–1902), long a schoolmistress in Finland. The aesthetic critic and poet, Carl Rupert Nyblom (1832–1907), continued the studies, translations and original pieces which had created him a reputation as one of the most accomplished general writers of Sweden. His wife, Helene Nyblom, was well known as a novelist. A. T. Gellerstedt (b. 1836), an architect of position, was known as a poet of small range but of very fine quality. Among writers of the earlier generation were Achatius Johan Kahl (1794–1888), the biographer of Tegnér; Per Erik Bergfalk (1798–1890), the critic and supporter of Geijer; the distinguished historian and academician, Karl Johan Schlyter (1795–1888) and the historical writers, Fredrik Ferdinand Carlson (1811–1887), Vilhelm Erik Svedelius (1816–1889), and Martin Weibull (1835–1902). The work of King Oscar II. (*q.v.*) himself had given him a worthy place among the intellectuals of the country. But the interest of such veteran reputations is eclipsed by the more modern school.

The serenity of Swedish literature was rudely shaken about 1884 by an incursion of realism and by a stream of novel and violent imaginative impulse. The controversy between the old and the new schools raged so fiercely, and the victory has remained so obviously in the hands of the latter, that it is difficult, especially for a foreigner, to hold the balance perfectly even. It will therefore be best in this brief sketch to say that the leader of the elder school was Viktor Rydberg (*q.v.*; 1828–1895) and that he was ably supported by Carl Snoilsky (*q.v.*; 1841–1904) who at the beginning of the 20th century was the principal living poet of the bygone generation in Sweden. Snoilsky was prominent for the richness of his lyrical style, his cosmopolitan interests and his great width of culture. Carl David af Wirsén (b. 1842) distinguished himself, and made himself very unhappy, by his dogged resistance to every species of renaissance in Swedish thought, or art, or literature. A man of great talent, he was a violent reactionary, and suffered from the consequences of an attitude so unpopular. He found a vehicle for his criticism in the *Post och Inrikes Tidningar*, of which he was editor. He published his *Lyrical Poems* in 1876; *New Lyrical Poems* in 1880; *Songs and Sketches* in 1885.

The Modern Movement.

Four influences may be mentioned as having acted upon young Sweden, and as having combined to release its literature from the old hard-bound conventions. These are English philosophy in the writings of Herbert Spencer, French realism in the practice and the preaching of Zola, Norwegian drama mainly through Ibsen, and Danish criticism in the essays and monographs of Georg Brandes. Unquestionably the greatest name in recent Swedish literature is that of Johan August Strindberg (*q.v.*; b. 1849). His drama of *Master Olof* in 1878 began the revolutionary movement. In 1879 the success of his realistic novel, *The Red Room*, fixed universal attention upon his talent. It was the sensation caused in 1884 by the lawsuit brought against Strindberg's *Married* (a collection of short stories dealing realistically with some of the seamy sides of marriage) which brought to a head the rebellion against the elegant and superficial conventions which were strangling Swedish literature. He affronts every canon of taste, more by a radical absence, it would seem, of the sense of proportion than by any desire to shock. His diatribes against woman suggest a touch of madness, and he was in fact at one time seized with an attack of insanity. He writes like a man whose view is distorted by physical or mental pain. His phraseology and his turns of invention are too empirically pseudoscientific for the simplicity of nature. With all these faults, and in spite of a terrible vulgarity of mind, an absence of humour, and a boundless confidence in the philosophy of Nietzsche, Strindberg is a writer of very remarkable power and unquestionable originality. His mind underwent singular transformations. After devoting himself wholly to realism of the coarsest kind, he began in 1889 his series of mystico-pathological novels about life in the archipelago of Stockholm. This led him to a *culte du moi*, of which the strangest result was an autobiography of crude invective, *A Fool's Confession* (1893), the printing of which in Swedish was forbidden. He rapidly passed on, through books like *Inferno* (1897), the diary of a semi-lunatic, up into the sheer mysticism of *To Damascus* (1898), where he reconciles himself at last to Christianity. His best work is classic in its breadth of style, exquisite in local colour and fidelity to the national characteristics of Sweden.

A curious antidote to the harsh pessimism of Strindberg was offered by the delicate and fantastic temperament of Ola Hansson (b. 1860), whose poems came prominently before the public in 1884, and who, in *Sensitiva amorosa* (1887), preached a gospel of austere self-restraint. Hansson has been as ardent in the idolatry of woman as Strindberg has been in his hostility to the sex. Of those who have worked side by side with Strindberg, the most prominent and active was Gustaf af Geijerstam (b. 1858), in his curious and severely realistic studies of country life in his *Poor People* (1884) and other books. In 1885 he produced a gloomy sketch of student life at Upsala, *Erik Grane*, which made a great sensation. Since then Geijerstam has published more than forty volumes, and has become one of the most popular writers of the north of Europe. A melancholy interest surrounds the name of Victoria Benedictsson (Ernst Ahlgren, 1850–1889), who committed suicide in Copenhagen after achieving marked success with her sketches of humble life in *Från Skåne*, and with the more ambitious works *Money* and *Marianne*. She was perhaps the most original of the many women writers of modern Sweden, and *Money* was hailed by Swedish critics as the most important work of fiction since Strindberg's *Red Room*. Her biography, a most affecting narrative, was published by Ellen Key, and her autobiography by Axel Lundegård (b. 1861), who, after some miscellaneous writing, produced in 1889 a curious novel of analysis called *The Red Prince*, and who, becoming a devout clerical, published a number of popular stories in a neo-romantic manner. In 1898–1900 he produced a historical trilogy, *Struensee*, tracing the career of the minister from his early years as a doctor in Altona to his final downfall. In 1904 appeared the first volume of a second historical trilogy, *The Story of Queen Philippa*. Fru Alfhild Agrell (née Martin), who was born in 1849, produced a series of plays dealing with the woman question, *Rescued* (1883) and others. She also showed great ability as a novelist, among the best of her books being a series of sketches of country life (1884–1887). An historical novelist of unequal powers, but great occasional merit, is Matilda Malling, née Kruse (b. 1864), whose romance about Napoleon (1894) enjoyed a huge success. Tor Hedberg (b. 1861) also began as a decided realist, and turned to a more psychological and idealist treatment of life. His most striking work was *Judas* (1886); he has written some excellent dramas. Late successes in the novel has been those of Hilma Angered-Strandberg (*On the Prairie*, 1898) and Gustaf Janson (*Paradise*, 1900). The most remarkable of the novelists of the latest group is Selma Lagerlöf (b. 1858), who achieved a great success with *Gösta Berlings Saga* in 1891–1892. She employs the Swedish language with an extraordinary richness and variety, and stands in the front rank of Swedish novelists. But perhaps the most cosmopolitan recent novelist of Sweden is Per Hallström (b. 1866), who spent much of his youth in America, and appeared as an imaginative writer first in 1891. He has published volumes of ballads, short stories and sketches, fantastic and humoristic, all admirable in style. His play, *A Venetian Comedy*, enjoyed a substantial success in 1904.

Among the recent lyrical poets of Sweden, the first to adopt the naturalistic manner was Albert Ulrik Bååth (b. 1853), whose earliest poems appeared in 1879. In his rebellion against the sweetness of Swedish convention he proved himself somewhat indifferent to beauty of form, returned to "early national" types of versification, and concentrated his attention on dismal and distressing conditions of life. He is a resolute, but, in his early volumes, harsh and rocky writer. From 1882 onwards Bååth was steadily productive. Karl Alfred Melin (b. 1849) has described in verse the life in the islands of the Stockholm archipelago. Among lyrists who have attracted attention in their various fields are Oskar Levertin (1862–1906) and Emil Kléen (1868–1898). Of these Levertin is the more highly coloured and perfumed, with an almost Oriental richness; Kléen has not been surpassed in the velvety softness of his language. But by far the most original and enjoyable lyrical genius of the later period is that of Gustaf Fröding (b. 1860), whose collection of poems, called *Guitar and Accordion*, humorous, amatory and pathetic, produced a great sensation in 1891. Three other volumes followed in 1894, 1895 and 1897, each displaying to further advantage the versatility and sensuous splendour of Fröding's talent, as well as its somewhat scandalous recklessness. In 1897 he was struck down with insanity, and after three months' confinement in the asylum at Upsala, although he recovered his senses, all his joyousness and wildness had left him. He became gloomily religious, and in a new volume of poems he denounced all that he valued and enjoyed before his conversion. A younger poet is K. G. Ossian-Nilssen (b. 1875), the author of several volumes of vigorous dramatic and satiric verse.

The writer who was exercising most influence in Sweden at the opening of the 20th century was Verner von Heidenstam (b. 1859). He started authorship with a book of verse in 1888, after which time he led a reaction against realism and pessimism, and has turned back to a rich romantic idealism in his novels of *Endymion* (1889) and *Hans Alienus* (1892), and in his stories (1897) of the time of Charles XII. Heidenstam also published interesting volumes of literary criticism, and he is a lyrical poet of very high attainment. Miss Ellen Key (b. 1849), a secularist lecturer of great fervour, became an author in biographical and critical studies of remarkable originality. She is distinguished from Selma Lagerlöf, who is simply an artist, by her exercise of pure intellect; she is a moral leader; she has been called "the Pallas of Sweden." She published in 1897 a biography of the Swedish author, Almqvist; in 1899 she collected her finest essays in the volume called *Thought Pictures*; in 1900 appeared, under the title *Human Beings*, studies of the Brownings and of Goethe; but the finest of Ellen Key's books is *The Century of Childhood* (1901), a philosophical survey of the progress of elementary education in the last hundred years. She exercises a very remarkable power over the minds of the latest generation in Sweden. A polemical essayist of elaborate delicacy of style is Hjalmar Söderberg (b. 1869), who has been influenced by Strindberg and by Anatole

France. His ironic romance, *Martin Birck's Youth*, created a sensation in 1901. Karl Johan Warburg (b. 1852) has done good work both as an essayist and as an historian of literature. But in this latter field by far the most eminent recent name in Swedish literature is that of Professor Johan Henrik Schück (b. 1855), who has made great discoveries in the 16th and 17th centuries, and who has published, besides a good book about Shakespeare, studies in which a profound learning is relieved by elegance of delivery. Warburg and Schück have written an excellent history of Swedish literature down to 1888. The poet Levertin, who was also a distinguished critic, wrote a good book about the Swedish theatre. Drama has rarely flourished in Sweden, but several of the poets mentioned above have written important plays, and, somewhat earlier, the socialistic problem-pieces of Anne Charlotte Edgren-Leffler, duchess of Cajanello (1849–1893), possessed considerable dramatic talent, working under a direct impulse from Ibsen; but her greatest gift was as a novelist. The plays of Harald Johan Molander (1858–1900) have been popular in the theatres of Sweden and Finland since his first success with *Rococo* in 1880. Altogether a remarkable revival of belles-lettres has taken place in Sweden after a long period of inertness and conventionality. It is regrettable, for its own sake, that the Swedish Academy, which in earlier generations had identified itself with the manifestations of original literary genius, has closed its doors to the new writers with an almost vindictive pertinacity.

Swedish Philosophy.—Swedish philosophy proper began in the 17th century with the introduction of Cartesianism. The protagonist of the movement was J. Bilberg (1646–1717), who, in various theses and discussions, defended the new ideas against the scholastic Aristotelianism of the orthodox churchmen. A. Rydelius (1671–1738), an intimate friend of Charles XII., endeavoured to find a common ground for the opposing schools, and the Leibnitzio-Wolffian philosophy was maintained by N. Wallerius (1706–1764). Towards the close of the 18th century, a number of thinkers began to expound the philosophy of the Enlightenment under the influence of English and French ideas—J. H. Kellgren (1751–1795), K. G. af Leopold (1756–1829), T. Thorild (1759–1808), K. A. Ehrensvärd (1745–1800); while the Kantian dialectic was worthily defended by D. Boëthius (1751–1810), whose work paved the way for a great idealistic speculative movement headed by B. Höijer (1767–1812), the poet P. D. A. Atterbom (1790–1855), a follower of Schelling, and J. J. Borelius (b. 1823), the great Swedish exponent of Hegelianism.

All the above thinkers reflected the general development of European thought. There exists, however, a body of thought which is the product of the peculiar genius of the Swedish people, namely, the development of the individual soul in accordance with a coherent social order and a strong religious spirit. This *Personal Philosophy* owes its development to K. J. Boström (*q.v.*), and, though traceable ultimately to Schelling's idealism, received its distinctive character from the investigations of N. F. Biberg (1776–1827), S. Grubbe (1786–1853) and E. G. Geijer (*q.v.*) (1783–1847), all professors at Upsala. Boström's philosophy is logically expressed and based on the one great conception of a spiritual, eternal, immutable Being, whose existence is absolute, above and external to the finite world of time and space. It has for a long time exercised almost unquestioned authority over Swedish thought, religious and philosophical. It is strong in its unequivocal insistence on personal purity and responsibility, and in the uncompromising simplicity of its fundamental principle. Boström wrote little, but his views are to be found in the works of two groups of thinkers. The older group includes S. Ribbing (1816–1899), C. Y. Sahlin (b. 1824), K. Claëson (1827–1859), H. Edfeldt (b. 1836), the editor of Boström's works, A. Nyblaeus (1821–1899) and P. J. H. Leander (b. 1831); the younger writers, less in agreement with one another, but adhering in the main to the same tradition, are E. O. Burman (b. 1845), K. R. Geijer (b. 1849), L. H. Åberg (1851–1895), F. v. Schéele (b. 1853), J. V. A. Norström (b. 1856), of Gothenburg, and P. E. Liljeqvist (b. 1865), of Lund. Of these, Nyblaeus compiled a lucid account of Swedish philosophy from the beginning of the 18th century up to and including Boström; Ribbing (*Platos Ideelära* and *Socratische Studien*) showed how closely Swedish idealism is allied to Greek. P. Wikner (1837–1888) broke away from the Boströmian tradition and followed out a path of his own in a more essentially religious spirit. V. Rydberg (*q.v.*) (1828–1895) closely followed Boström, and in his numerous and varied writings did much to crystallize and extend the principles of idealism. Among prominent modern writers may also be mentioned H. Larsson and A. Herrlin at Lund, and A. Vannerus in Stockholm.

Authorities.—The *Svecia litterata* (1680) of J. Schefferus (1621–1679) is the first serious attempt at a bibliography of Swedish literature. The *Svenska siare och skalder* (Upsala, 1841–1855) contains an admirable series of portraits of Swedish writers up to the end of the reign of Gustavus III.; many of Atterbom's judgments are reversed in the *Grunddragen af Svenska vitterhetens historia* (1866–1868) of B. E. Malmström; and a body of excellent criticism of the subsequent period was supplied by G. Ljunggren in his *Svenska vitterhetens häfder från Gustaf död* (1818–1819; new ed. by Sondén III.'s. 1833), which remains a classic exposition of the views of the romanticists. The history of Swedish letters as it reflects the life of the nation is dealt with by C. R. Nyblom, *Estetiska studier* (Stockholm, 1873–1884). Among general works on the subject, see H. Schück, *Svensk literaturhistoria* (1885, &c.) Schück and Warburg, *Illustrerad Svensk literatur historia* (1896); H. Paul, *Grundriss der germanischen Philologie* (new ed., Strassburg, 1901, &c.). The official handbook of *Sweden* prepared by the Swedish Central Bureau of Statistics for the Paris Exhibition (English ed., Stockholm, 1904); Ph. Schweitzer, *Geschichte der skandinavischen Litteratur*, forming vol. viii. of *Geschichte der Welt Litteratur in Einzeldarstellungen* (Leipzig, 3 pts., 1886–1889); Oscar Levertin, *Svenska Gestalter* 1904. (E. G.)

SWEDENBORG (or Swedberg), **EMANUEL** (1688–1772), Swedish scientist, philosopher and mystic, was born at Stockholm on the 29th of January 1688. His father, Dr Jesper Swedberg, subsequently professor of theology at Upsala and bishop of Skara, was a pious and learned man, who did not escape the charge of heterodoxy, seeing that he placed more emphasis on the cardinal virtues of faith, love and communion with God than on the current dogmas of the Lutheran Church. Having completed his university course at Upsala, in 1710, Swedenborg undertook a European tour, visiting England, Holland, France and Germany, studying especially natural philosophy and writing Latin verses, a collection of which he published in 1710. In 1715 he returned to Upsala, and devoted himself to natural science and various engineering works. From 1716 to 1718 he published a scientific periodical, called *Daedalus hyperboreus*, a record of mechanical and mathematical inventions and discoveries. In 1716 he was introduced to Charles XII., who appointed him assessor-extraordinary on the Swedish board of mines. His reports on smelting and assaying were remarkable for their detail and for the comparisons drawn between Swedish and other methods. Two years later he distinguished himself at the king's siege of Frederikshall by the invention of machines for the transport of boats and galleys overland from Stromstadt to Iddefjord, a distance of 14 m. The same year he published various mathematical and mechanical works. At the death of Charles XII. Queen Ulrica elevated him and his family to the rank of nobility, by which his name was changed from Swedberg to Swedenborg, the "en" corresponding to the German "von." In the Swedish House of Nobles his contributions to political discussion had great influence, and he dealt with such subjects as the currency, the decimal system, the balance of trade and the liquor laws (where he was the pioneer of the Gothenburg system) with marked ability. He strongly opposed a bill for increasing the power of the crown. The next years were devoted to the duties and studies connected with his office, which involved the visitation of the Swedish, Saxon, Bohemian and Austrian mines. In 1724 he was offered the chair of mathematics in the university of Upsala, which he declined, on the ground that it was a mistake for mathematicians to be limited to theory. His inquiring and philosophical mind gradually led him to wider studies. As early as 1721 he was seeking to lay the foundation of a scientific explanation of the universe, when he published his *Prodromus principiorum rerum naturalium*, and had already written his *Principia* in its first form. In 1734 appeared in three volumes (*Opera philosophica et mineralia*, the first volume of which (his *Principia*) contained his view of the first principles of the universe, a curious mechanical and geometrical theory of the origin of things. The other volumes dealt with (*a*) iron and steel, (*b*) copper and brass, their smelting, conversion and assaying, and chemical experiments thereon.

There is no doubt that Swedenborg anticipated many scientific facts and positions that are usually regarded as of much more modern date. It was only towards the end of the 19th century that his voluminous writings began to be properly collected and examined, with the result of proving that there was hardly one department of scientific activity in which he was not far ahead of his time. His work on palaeontology shows him the predecessor of all the Scandinavian geologists, and his contributions in this field alone would have been sufficient to perpetuate his fame. He was also a great physicist and had arrived at the nebular hypothesis theory of the formation of the planets and the sun long before Kant and Laplace. His theory of light and theory of the cosmic atoms were equally astonishing. He wrote a lucid account of the phenomena of phosphorescence, and adduced a molecular magnetic theory which anticipated some of the chief features of the hypothesis of to-day. The great French chemist, Dumas, gives him the credit for the first attempt to establish a system of crystallography. He was the first to employ mercury for the air-pump, and devised a method of determining longitude at sea by observations of the moon among the stars. He suggested the use of experimental tanks for testing the powers of ship models, invented an ear-trumpet for the deaf, improved the common house-stove of his native land, cured smoky chimneys, took a lively interest in machine-guns and even sketched a flying machine.

This flying machine consisted of a light frame covered with strong canvas and provided with two large oars or wings moving on a horizontal axis, and so arranged that the upstroke met with no resistance while the downstroke provided the lifting power. Swedenborg knew that the machine would not fly, but suggested it as a start and was confident that the problem would be solved. He said " It seems easier to talk of such a machine than to put it into actuality, for it requires greater force and less weight than exists in a human body. The science of mechanics might perhaps suggest a means, namely, a strong spiral spring. If these advantages and requisites are observed, perhaps in time to come some one might know how better to utilize our sketch and cause some addition to be made so as to accomplish that which we can only suggest. Yet there are sufficient proofs and examples from nature that such flights can take place without danger, although when the first trials are made you may have to pay for the experience, and not mind an arm or leg."

In 1734 he also published *Prodromus philosophiae ratiocinantis de infinito et causa finali creationis*, which treats of the relation of the finite to the infinite, and of the soul to the body, seeking to establish a nexus in each case as a means of overcoming the difficulty of their relation. From this time he applied himself to the problem of discovering the nature of soul and spirit by means of anatomical studies. In all his researches he acknowledged and contended for the existence and the supremacy of the spiritual and the divine. He travelled in Germany, France and Italy, in quest of the most eminent teachers and the best books dealing with the human frame, and published, as the results of his inquiries among other works, his *Oeconomia regni animalis* (London, 1740–1741) and *Regnum animale* (the Hague, 1744–1745; London, 1745). In no field were Swedenborg's researches more noteworthy than in those of physiological science. In 1901, Professor Max Neuberger of Vienna called attention to certain anticipations of modern views made by Swedenborg in relation to the functions of the brain. The university of Vienna appealed to the Royal Swedish Academy for a complete issue of the scientific treatises, and this resulted in the formation of a committee of experts who have been entrusted with the task. It is clear that Swedenborg showed (150 years before any other scientist) that the motion of the brain was synchronous with the respiration and not with the action of the heart and the circulation of the blood, a discovery the full bearings of which are still far from being realized. He had arrived at the modern conception of the activity of the brain as the combined activity of its individual cells. The cerebral cortex, and, more definitely, the cortical elements (nerve cells), formed the seat of the activity of the soul, and were ordered into departments according to various functions. His views as to the physiological functions of the spinal cord are also in agreement with recent research, and he anticipated many of the pre-eminent offices of the ductless glands which students of the present time are only beginning to discover.

Up to middle age Swedenborg's position was that of a scholar, a scientist, a practical administrator, a legislator, and a man of affairs. But a profound change was coming over him, which led him to leave the domain of physical research for that of psychical and spiritual inquiry. Neither by geometrical, nor physical, nor metaphysical principles had he succeeded in reaching and grasping the infinite and the spiritual, or in elucidating their relation to man and man's organism, though he had caught glimpses of facts and methods which he thought only required confirmation and development. Late in life he wrote to Oetinger that " he was introduced by the Lord first into the natural sciences, and thus prepared, and, indeed, from the year 1710 to 1745, when heaven was opened to him." This latter great event is described by him in a letter to Thomas Hartley, rector of Winwick, as " the opening of his spiritual sight," " the manifestation of the Lord to him in person," " his introduction into the spiritual world." Before his illumination he had been instructed by dreams, and enjoyed extraordinary visions, and heard mysterious conversations. According to his own account, the Lord filled him with His spirit to teach the doctrines of the New Church by the word from Himself; He commissioned him to do this work, opened the sight of his spirit, and so let him into the spiritual world, permitting him to see the heavens and the hells, and to converse with angels and spirits for years; but he never received anything relating to the doctrines of the church from any angel but from the Lord alone while he was reading the word (*True Christian Religion*, No. 779). He elsewhere speaks of his office as principally an opening of the spiritual sense of the word. His friend Robsahm reports, from Swedenborg's own account to him, the circumstances of the first extraordinary revelation of the Lord, when He appeared to him and said, " I am God the Lord, the Creator and Redeemer of the world. I have chosen thee to unfold the spiritual sense of the Holy Scripture. I will Myself dictate to thee what thou shalt write." From that time he gave up all worldly learning and laboured solely to expound spiritual things. In the year 1747, to the great regret of his colleagues, he resigned his post of assessor of the board of mines that he might devote himself to his higher vocation, requesting only to be allowed to receive as a pension the half of his salary. He took up afresh his study of Hebrew, and began his voluminous works on the interpretation of the Scriptures. His life from 1747 was spent alternately in Sweden, Holland and London, in the composition of his works and their publication, till his death, which took place in London on the 29th of March 1772. He was buried in the Swedish church in Princes Square, in the parish of St George's-in-the-East, and on the 7th of April 1908 his remains were removed at the request of the Swedish government to Stockholm.

Swedenborg was a man who won the respect, confidence and love of all who came into contact with him. Though people might disbelieve in his visions, they feared to ridicule them in his presence. Those who talked with him felt that he was truth itself. He never disputed on matters of religion, and if obliged to defend himself, did it with gentleness and in a few words. His manner of life was simple in the extreme; his diet consisted chiefly of bread and milk and large quantities of coffee. He paid no attention to the distinction of day and night, and sometimes lay for days together in a trance, while his servants were often disturbed at night by hearing what he called his conflicts with evil spirits. But his intercourse with spirits was often perfectly calm, in broad daylight, and with all his faculties awake. Three extraordinary instances are produced by his friends and followers in proof of his seership and admission into the unseen world. But there exists no account at first hand of the exact facts, and Swedenborg's own reference to one of these instances admits of another explanation than the supernatural one. Immanuel Kant was struck by them in 1763, but in 1765, after further inquiries, concluded that two of them had " no other foundation than common report (*gemeine Sage*)." See Kehrbach's edition of Kant's *Träume eines Geistersehers* (Leipzig, 1880).

As a theologian Swedenborg never attempted to preach or to found a sect. He believed that members of all the churches could belong to the New Church without forming a separate organization. His theological writings roughly fall into four groups: (1) books of spiritual philosophy, including *The Divine Love and Wisdom*, *The Divine Providence*, *The Intercourse between the Soul and the Body*, *Conjugial Love*; (2) Expository, including *Arcana Celestia* (giving the spiritual sense of Genesis and Exodus), *The Apocalypse Revealed*, *The Apocalypse Explained*; (3) Doctrinal, including *The New Jerusalem and its Heavenly Doctrines*, *The Four Chief Doctrines*, *The Doctrine of Charity*, *The True Christian Religion*, *Canons of the New Church*; (4) Eschatological, including *Heaven and Hell*, and *The Last Judgment*. About forty volumes are available in English, and many have been translated into most of the European languages as well as into Arabic, Hindi and Japanese.

Swedenborg's theosophic system is most briefly and comprehensively presented in his *Divine Love and Wisdom.* The point of view from which God must be regarded is that of His being the Divine Man. His *esse* is infinite love; His manifestation, form or body is infinite wisdom. Divine love is the self-subsisting life of the universe. From God emanates a divine sphere, which appears in the spiritual world as a sun, and from this spiritual sun again proceeds the sun of the natural world. The spiritual sun is the source of love and intelligence, or life, and the natural sun the source of nature or the receptacles of life; the first is alive, the second dead. The two worlds of nature and spirit are perfectly distinct, but they are intimately related by analogous substances, laws and forces. Each has its atmospheres, waters and earths, but in the one they are natural and in the other spiritual. In God there are three infinite and uncreated "degrees" of being, and in man and all things corresponding three degrees, finite and created. They are love, wisdom, use; or end, cause and effect. The final ends of all things are in the Divine Mind, the causes of all things in the spiritual world, and their effects in the natural world. By a love of each degree man comes into conjunction with them and the worlds of nature, spirit and God. The end of creation is that man may have this conjunction and become the image of his Creator and creation. In man are two receptacles for God—the will for divine love and the understanding for divine wisdom—that love and wisdom flowing into both so that they become human. Before the fall this influx was free and unhindered, and the conjunction of man with God and the creation complete, but from that time the connexion was interrupted and God had to interpose by successive dispensations. At last the power and influence of the spirits of darkness, with whom man associates himself by his sin, became so great that the existence of the human race was threatened, and Jehovah was necessitated to descend into nature to restore the connexion between Himself and man. He could not come in His unveiled divinity, for the "hells" would have then perished, whom he did not seek to destroy but only to subjugate. Another purpose of Jehovah's incarnation was the manifestation of His divine love more fully than ever before. Swedenborg wholly rejects the orthodox doctrine of atonement; and the unity of God, as opposed to his idea of the trinity of the church, is an essential feature of his teaching. Another distinctive feature is that Jehovah did not go back to heaven without leaving behind him a visible representative of Himself in the word of the Scripture. This word is an eternal incarnation, with its threefold sense—natural, spiritual, celestial. And Swedenborg is the divinely commissioned expounder of this threefold sense of the word, and so the founder of the New Church, the paraclete of the last dispensation. That he might perceive and understand the spiritual and the celestial senses of the word he enjoyed immediate revelation from the Lord, was admitted into the angelic world, and had committed to him the key of "correspondences" with which to unlock the divine treasures of wisdom. Swedenborg claimed also to have learnt by his admission into the spiritual world the true states of men in the next life, the scenery and occupations of heaven and hell, the true doctrine of Providence, the origin of evil, the sanctity and perpetuity of marriage and to have been a witness of the "last judgment," or the second coming of the Lord, which is a contemporary event. "All religion," he said, "has relation to life, and the life of religion is to do good." "The kingdom of Heaven is a kingdom of uses." He exercised a great influence over S. T. Coleridge, Robert and Elizabeth Browning, Coventry Patmore, Henry Ward Beecher and Thomas Carlyle. And the attention of modern psychologists is now being drawn to his doctrine of the relation of the elements of the universe to the membranes of the body.

Swedenborgianism, as professed by Swedenborg's followers, is based on the belief of Swedenborg's claims to have witnessed the last judgment, or the second advent of the Lord, with the inauguration of the New Church, through the new system of doctrine promulgated by him and derived from the Scriptures, into the true sense of which he was the first to be introduced. The "doctrines" of the New Church as given in the *Liturgy* (which also contains the "Creed" and "Articles of Faith") are as follows:—

1. That there is one God, in whom there is a Divine Trinity; and that He is the Lord Jesus Christ.
2. That a saving faith is to believe on Him.
3. That evils are to be shunned, because they are of the devil and from the devil.
4. That good actions are to be done, because they are of God and from God.
5. That these are to be done by a man as from himself; but that it ought to be believed that they are done from the Lord with him and by him.

Swedenborgians now constitute a widely spread and considerable society, with a regularly constituted ecclesiastical organization and a zealous missionary activity (see New Jerusalem Church).

See R. L. Tafel, *Documents concerning the Life and Character of Swedenborg*, collected, translated and annotated (3 vols., Swedenborg Society, 1875–1877); J. Hyde, *A Bibliography of the Works of Emanuel Swedenborg* (743 pp., Swedenborg Society). Of English lives the principal are those by J. J. G. Wilkinson (London, 1849); E. Paxton Hood (London, 1854); William White (1856, rewritten in 1867 and in 1868); G. Trobridge (London, 1907); also *Emanuel Swedenborg, the Spiritual Columbus, a Sketch*, by U. S. E. (2nd ed., London, 1877). Some of his writings, *e.g. The Divine Providence* and *Heaven and Hell* have been published in popular editions. A useful handbook of Swedenborg's theology is the *Compendium of the Theological Writings of Emanuel Swedenborg* by the Rev. Samuel Warren (London, 1885). Summaries of his system and writings are given in all the above biographies, also in Edmund Swift, *Manual of the Doctrines of the New Church* (London, 1885); and T. Parsons, *Outlines of Swedenborg's Religion and Philosophy*. Important critiques from independent points of view are "The Mystic," in R. W. Emerson's *Representative Men* (1850); Kant's *Träume eines Geistersehers* (1766; the best edition by Kehrbach, Leipzig, 1880); J. G. Herder's "Emanuel Swedenborg," in his *Adrastea* (*Werke zur Phil. und Gesch.*, xii. 110–125); J. J. von Goerres's *Emanuel Swedenborg, seine Visionen und sein Verhältniss zur Kirche* (1827); A. Dorner's *Geschichte der protestantischen Theologie*, pp. 662–667 (Munich, 1867). See also *Transactions of the International Swedenborg Congress* (London, 1910), summarized in *The New Church Magazine* (August, 1910). (A. J. G.)

SWEETBREAD, a popular term for certain glands of animals, particularly when used as articles of food; these are usually the pancreas, the "stomach-sweetbread" of butchers, and the thymus, or "breast sweetbread." The term is also sometimes used to include the salivary and lymphatic glands (see Ductless Glands, Pancreas and Lymphatic System).

SWEET POTATO. This plant, known botanically as *Ipomaea batatas* (formerly as *Convolvulus batatas*), and a member of the natural order Convolvulaceae, is generally cultivated in most tropical countries for the sake of its tuberous root, which is an article of diet greatly in request. It is a climbing perennial with entire or palmately-lobed leaves very variable in shape borne on slender twining stems. The flowers are borne on long stalks in loose clusters or cymes, and have a white or rosy funnel-shaped corolla like that of the common bindweed of English hedges. The edible portion is the root, which dilates into large club-shaped masses filled with starch. It is ill suited to the climate of the United Kingdom, but in tropical countries it is as valuable as the potato is in higher latitudes. The plant is not known in a truly wild state, nor has its origin been ascertained. A. de Candolle concludes that it is in all probability of American origin, where it has been cultivated from prehistoric times by the aborigines. It is mentioned by Gerard as the "potato," or "potatus" or "potades," in contradistinction to the "potatoes" of Virginia (*Solanum tuberosum*). He grew it in his garden, but the climate was not warm enough to allow it to flower, and in winter it perished and rotted. But as the appellation "common" is applied to them the roots must have been introduced commonly. Gerard tells us he bought those that he planted at "the Exchange in London," and he gives an interesting account of the uses to which they were put, the manner in which they were prepared as "sweetmeats," and the invigorating properties assigned to them. The allusions in the *Merry Wives of Windsor* and other of Shakespeare's plays in all probability refer to this plant, and not to what we now call the "potato." The plants require a warm sunny climate, long season, and a liberal supply of water during the growing season. For an account of the cultivation in North America, where large quantities are grown in the Southern states, see L. H. Bailey, *Cyclopaedia of American Horticulture* (1902). Sir George Watt, *Dictionary of the Economic Products of India* (1890), gives an account of its cultivation in India, where some confusion has arisen by the use of the name batatas for the yam (*q.v.*); the author suggests that the introduction of the sweet potato into India is comparatively recent.

SWEET-SOP, or Sugar Apple, botanical name *Anona squamosa*, a small tree or shrub with thin oblong-ovate leaves, solitary greenish flowers and a yellowish-green fruit, like a shortened pine cone in shape with a tubercle corresponding to each of the carpels from the aggregation of which it has been formed. The fruit is 3 to 4 in. in diameter and contains a sweet creamy-yellow custard-like pulp. It is a native of the West Indies and tropical America; it is much prized as a fruit, and has been widely introduced into the eastern hemisphere.

Another species, *A. muricala*, is the sour-sop, a small evergreen tree bearing a larger dark-green fruit, 6 to 8 in. long and 1 to 5 lb in weight, oblong or bluntly conical in shape, with a rough spiny skin and containing a soft white juicy subacid pulp with a flavour of turpentine. It is a popular fruit in the West Indies, where it is native, and is grown with special excellence in Porto Rico. A drink is made from the juice. *A. reticulata* is the custard apple (*q.v.*) and *A. palustris* the alligator apple.

SWELLENDAM, a town of South Africa, Cape province, in the valley of the Breede River, 192 m. by rail E. by S. of Cape Town. Pop. (1904), 2406, of whom 1139 were white. Swellendam is one of the older Dutch settlements in the Cape, dating from 1745, and was named after Hendrik Swellengrebel (then governor of the Cape) and his wife, whose maiden name was Damme. Early in 1795 the burghers of the town and district rose in revolt against the Dutch East India Company, proclaimed a "free republic," and elected a so-styled national assembly. At the same time the burghers of Graaff Reinet also rebelled against the Cape authorities, who were powerless to suppress the insurrectionary movement. One of the claims of the "free republic" was "the absolute and unconditional slavery of all Hottentots and Bushmen." In September of that year Cape Town surrendered to the British and the "National" party at Swellendam quietly accepted British rule.

The town is a trading centre of some importance, and in the surrounding district are large sheep and ostrich farms. The neighbourhood is noted for its abundance of everlasting flowers.

SWETCHINE, MADAME (1782–1857), Russian mystic, whose maiden name was Soymanof, was born in Moscow, and under the influence of Joseph de Maistre became a member of the Roman Catholic Church in 1815. In the following year she settled in Paris where, until her death, she maintained a famous salon remarkable no less for its high courtesy and intellectual brilliance than for its religious atmosphere. Though not physically beautiful she had a personality of rare spiritual charm, nurtured in the private chapel of her house. Her husband, General Swetchine, was 25 years her senior. Her *Life and Works* (of which the best known are "Old Age" and "Resignation") were published by M. de Falloux (2 vols., 1860) and her *Letters* by the same editor (2 vols., 1861).

SWEYN I., King of Denmark (–1014), son of Harold Bluetooth, the christianizer of Denmark, by his peasant mistress Aesa, according to the Jomsvikinga Saga, though more probably his mother was Queen Gunild, Harold's consort. The lad was a born champion and buccaneer. His first military expedition, in alliance with the celebrated Jomsborg Viking, Palnatoke, was against his own father, who perished during the struggle (*c.* 986). Six years later he conducted a large fleet of warships to England, which did infinite damage, but failed to capture London. During his absence, Denmark was temporarily occupied by the Swedish king, Eric Sersel, on whose death (*c.* 994) Sweyn recovered his patrimony. About the same time he repudiated his first wife Gunild, daughter of duke Mieszko of Poland, and married King Eric's widow, Sigrid. This lady was a fanatical pagan of a disquieting strength of character. Two viceroys, earlier wooers, were burned to death by her orders for their impertinence, and she refused the hand of Olaf Trygvessön, king of Norway, rather than submit to baptism, whereupon the indignant monarch struck her on the mouth with his gauntlet and told her she was a worse pagan than any dog. Shortly afterwards she married Sweyn, and easily persuaded her warlike husband to unite with Olaf, king of Sweden, against Olaf Trygvessön, who fell in the famous sea-fight off Svolde (1000) on the west coast of Rügen, after a heroic resistance immortalized by the sagas, whereupon the confederates divided his kingdom between them. After his first English expedition Sweyn was content to blackmail England instead of ravaging it, till the ruthless massacre of the Danes on St Brice's day, the 3rd of November 1002, by Ethelred the Unready (Sweyn's sister was among the victims) brought the Danish king to Exeter (1003). During each of the following eleven years, the Danes, materially assisted by the universal and shameless disloyalty of the Saxon ealdormen, systematically ravaged England, and from 991 to 1014 the wretched land is said to have paid its invaders in ransoms alone £158,000. Sweyn died suddenly at Gainsborough on the 13th of February 1014. The data relating to his whole history are scanty and obscure, and his memory has suffered materially from the fact that the chief chroniclers of his deeds and misdeeds were ecclesiastics. It was certainly unfortunate that he began life by attacking his own father. It is undeniable that his favourite wife was the most stiff-necked pagan of her day. His most remarkable exploit, Svolde, was certainly won at the expense of Christianity, resulting, as it did, in the death of the saintly Olaf. Small wonder, then, if Adam of Bremen, and the monkish annalists who follow him, describe Sweyn as a grim and bloody semi-pagan, perpetually warring against Christian states. But there is another side to the picture. Viking though he was, Sweyn was certainly a Christian viking. We know that he built churches; that he invited English bishops to settle in Denmark (notably Godibald, who did good work in Scania); that on his death-bed he earnestly commended the Christian cause to his son Canute. He was cruel to his enemies no doubt, but he never forgot a benefit. Thus he rewarded the patriotism of the Danish ladies who sacrificed all their jewels to pay the heavy ransom exacted from him by his captors, the Jomsborg pirates, by enacting a law whereby women were henceforth to inherit landed property in the same way as their male relatives. Of his valour as a captain and his capacity as an administrator there can be no question. His comrades adored him for his liberality, and the frequent visits of Icelandic skalder to his court testify to a love of poetry on his part, indeed one of his own strophes has come down to us. As to his personal appearance we only know that he had a long cleft beard, whence his nickname of *Tiugeskaeg* or Fork-Beard.

See *Danmarks riges historie. Oldtiden og den ældre middelalder*, pp. 364–381 (Copenhagen, 1897–1905). (R. N. B.)

SWIFT, JONATHAN (1667–1745), dean of St Patrick's, Dublin, British satirist, was born at No. 7 Hoey's Court, Dublin, on the 30th of November 1667, a few months after the death of his father, Jonathan Swift (1640–1667), who married about 1664 Abigaile Erick, of an old Leicestershire family. He was taken over to England as an infant and nursed at Whitehaven, whence he returned to Ireland in his fourth year. His grandfather, Thomas Swift, vicar of Goodrich near Ross, appears to have been a doughty member of the church militant, who lost his possessions by taking the losing side in the Civil War and died in 1658 before the restoration could bring him redress. He married Elizabeth, niece of Sir Erasmus Dryden, the poet's grandfather. Hence the familiarity of the poet's well-known "cooling-card" to the budding genius of his kinsman Jonathan: "Cousin Swift, you will never be a poet." The young Jonathan was educated mainly at the charges of his uncle Godwin, a Tipperary official, who was thought to dole out his help in a somewhat grudging manner. In fact the apparently prosperous relative was the victim of unfortunate speculations, and chose rather to be reproached with avarice than with imprudence. The youth was resentful of what he regarded as curmudgeonly treatment, a bitterness became ingrained and began to corrode his whole nature; and although he came in time to grasp the real state of the case he never mentioned his uncle with kindness or regard. At six he went to Kilkenny School, where Congreve was a schoolfellow; at fourteen he entered pensioner at Trinity College, Dublin, where he seems to have neglected his opportunities. He was referred in natural philosophy, including mathematics, and obtained his degree only by a special but by no means infrequent act of indulgence. The patronage of his uncle galled him: he was dull and unhappy. We find in Swift few signs of precocious genius. As with Goldsmith, and so many other men who have become artists of the pen, college proved a stepmother to him.

In 1688 the rich uncle, whose supposed riches had dwindled so much that at his death he was almost insolvent, died, having decayed, it would seem, not less in mind than in body and estate, and Swift sought counsel of his mother at Leicester. After a brief residence with his mother, who was needlessly alarmed at the idea of her son falling a victim to some casual coquette, Swift towards the close of 1689 entered upon an engagement as secretary to Sir William Temple, whose wife (Dorothy Osborne) was distantly related to Mrs Swift. It was at Moor Park, near Farnham, the residence to which Temple had retired to cultivate apricots after the rapid decline of his influence during the critical period of Charles II.'s reign (1679–1681), that Swift's acquaintance with Esther Johnson, the "Stella" of the famous *Journal*, was begun. Stella's mother was living at Moor Park, as servant or *dame de compagnie* of Temple's strong-minded sister, Lady Giffard. Swift was twenty-two and Esther eight years old at the time, and a curious friendship sprang up between them. He taught the little girl how to write and gave her advice in reading. On his arrival at Moor Park, Swift was, in his own words, a raw, inexperienced youth, and his duties were merely those of account-keeper and amanuensis: his ability gradually won him the confidence of his employer, and he was entrusted with some important missions. He was introduced to William III. during that monarch's visit to Sir William's, and on one occasion accompanied the king in his walks round the grounds. In 1693 Temple sent him to try and convince the king of the inevitable necessity of triennial parliaments. William remained unconvinced and Swift's vanity received a useful lesson. The king had previously taught him "how to cut asparagus after the Dutch fashion." Next year, however, Swift (who had in the meantime obtained the degree of M.A. *ad eundem* at Oxford) quitted Temple, who had, he considered, delayed too long in obtaining him preferment. A certificate of conduct while under Temple's roof was required by all the Irish bishops he consulted before they would proceed in the matter of his ordination, and after five months' delay, caused by wounded pride, Swift had to kiss the rod and solicit in obsequious terms the favour of a testimonial from his discarded patron. Forgiveness was easy to a man of Temple's elevation and temperament, and he not only despatched the necessary recommendation but added a personal request which obtained for Swift the small prebend of Kilroot near Belfast (January 1695), where the new incumbent carried on a premature flirtation with a Miss Jane Waring, whom he called "Varina." In the spring of 1696 he asked the reluctant Varina to wait until he was in a position to marry. Just four years later he wrote to her in terms of such calculated harshness and imposed such conditions as to make further intercourse virtually impossible.

In the meantime he had grown tired of Irish life and was glad to accept Temple's proposal for his return to Moor Park, where he continued until Temple's death in January 1699. During this period he wrote much and burned most of what he had written. He read and learned even more than he wrote. Moor Park took him away from brooding and glooming in Ireland and brought him into the corridor of contemporary history, an intimate acquaintance with which became the chief passion of Swift's life. His *Pindaric Odes*, written at this period or earlier, in the manner of Cowley, indicate the rudiments of a real satirist, but a satirist struggling with a most uncongenial form of expression. Of more importance was his first essay in satiric prose which arose directly from the position which he occupied as domestic author in the Temple household. Sir William had in 1692 published his *Essay upon Ancient and Modern Learning*, transplanting to England a controversy begun in France by Fontenelle. Incidentally Temple had cited the letters of Phalaris as evidence of the superiority of the Ancients over the Moderns. Temple's praise of Phalaris led to an Oxford edition of the *Epistles* nominally edited by Charles Boyle. While this was preparing, William Wotton, in 1694, wrote his *Reflections upon Ancient and Modern Learning*, traversing Temple's general conclusions. Swift's *Battle of the Books* was written in 1697 expressly to refute this. Boyle's *Vindication* and Bentley's refutation of the authenticity of Phalaris came later. Swift's aim was limited to co-operation in what was then deemed the well-deserved putting down of Bentley by Boyle, with a view to which he represented Bentley and Wotton as the representatives of modern pedantry, transfixed by Boyle in a suit of armour given him by the gods as the representative of the "two noblest of things, sweetness and light." The satire remained unpublished until 1704, when it was issued along with *The Tale of a Tub*. Next year Wotton declared that Swift had borrowed his *Combat des livres* from the *Histoire poëtique de la guerre nouvellement déclarée entre les anciens et les modernes* (Paris, 1688). He might have derived the idea of a battle from the French title, but the resemblances and parallels between the two books are slight. Swift was manifestly extremely imperfectly acquainted with the facts of the case at issue. Such data as he displays may well have been derived from no authority more recondite than Temple's own essay.

In addition to £100, Temple left to Swift the trust and profit of publishing his posthumous writings. Five volumes appeared in 1700, 1703 and 1709. The resulting profit was small, and Swift's editorial duties brought him into acrimonious relation with Lady Giffard. The dedication to King William was to have procured Swift an English prebend, but this miscarried owing to the negligence or indifference of Henry Sidney, earl of Romney. Swift then accepted an offer from Lord Berkeley, who in the summer of 1699 was appointed one of the lords justices of Ireland. Swift was to be his chaplain and secretary, but upon reaching Ireland Berkeley gave the secretaryship to a Mr Bushe, who had persuaded him that it was an unfit post for a clergyman. The rich deanery of Derry then became vacant and Swift applied for it. The secretary had already accepted a bribe, but Swift was informed that he might still have the place for £1000. With bitter indignation Swift denounced the simony and threw up his chaplaincy, but he was ultimately reconciled to Berkeley by the presentation to the rectory of Agher in Meath with the united vicarages of Laracor and Rathbeggan, to which was added the prebend of Dunlavin in St Patrick's—the total value being about £230 a year. He was now often in Dublin, at most twenty miles distant, and through Lady Berkeley and her daughters he became the familiar and chartered satirist of the fashionable society there. At Laracor, near Trim, Swift rebuilt the parsonage, made a fish-pond, and planted a garden with poplars and willows, bordering a canal. His congregation consisted of about fifteen persons, "most of them gentle and all of them simple." He read prayers on Wednesdays and Fridays to himself and his clerk, beginning the exhortation "Dearly beloved Roger, the Scripture moveth you and me in sundry places." But he soon began to grow tired of Ireland again and to pay visits in Leicester and London. The author of the *Tale of a Tub*, which he had had by him since 1696 or 1698, must have felt conscious of powers capable of far more effective exercise than reading-desk or pulpit at Laracor could supply; and his resolution to exchange divinity for politics must appear fully justified by the result. The *Discourse on the Dissensions in Athens and Rome* (September 1701), written to repel the tactics of the Tory commons in their attack on the Partition Treaties "without humour and without satire," and intended as a dissuasive from the pending impeachment of Somers, Orford, Halifax and Portland, received the honour, extraordinary for the maiden publication of a young politician, of being generally attributed to Somers himself or to Burnet, the latter of whom found a public disavowal necessary. In April or May 1704 appeared a more remarkable work. Clearness, cogency, masculine simplicity of diction, are conspicuous in the pamphlet, but true creative power told the *Tale of a Tub*. "Good God! what a genius I had when I wrote that book!" was his own exclamation in his latter years. It is, indeed, if not the most amusing of Swift's satirical works, the most strikingly original, and the one in which the compass of his powers is most fully displayed. In his kindred productions he relies mainly upon a single element of the humorous—logical sequence and unruffled gravity bridling in an otherwise frantic absurdity, and investing it with an air of sense. In the *Tale of a Tub* he lashes out in all directions. The humour, if less cogent and cumulative, is richer and more varied; the invention, too, is more daringly original and more completely out of the reach of ordinary faculties. The supernatural coats and the quintessential loaf may be paralleled but cannot be surpassed; and the book is throughout a mine of suggestiveness, as, for example, in the anticipation of Carlyle's clothes philosophy within the compass of a few lines. At the same time it wants unity and coherence, it attains no conclusion, and the author abuses his digressive method of composition and his convenient fiction of hiatuses in the original manuscript. The charges it occasioned of profanity and irreverence were natural, but groundless. There is nothing in the book inconsistent with Swift's professed and real character as a sturdy Church of England parson, who accepted the doctrines of his Church as an essential constituent of the social order around him, battled for them with the fidelity of a soldier defending his colours, and held it no part of his duty to understand, interpret, or assimilate them.

In February 1701 Swift took his D.D. degree at Dublin, and before the close of the year he had taken a step destined to exercise a most important influence on his life, by inviting two ladies to Laracor. Esther, daughter of a merchant named Edward Johnson, a dependant, and legatee to a small amount, of Sir William Temple's (born in March 1680), whose acquaintance he had made at Moor Park in 1689, and whom he has immortalized as "Stella,"[1] came over with her companion Rebecca Dingley, a poor relative of the Temple family, and was soon permanently domiciled in his neighbourhood. The melancholy tale of Swift's attachment will be more conveniently narrated in another place, and is only alluded to here for the sake of chronology. Meanwhile the sphere of his intimacies was rapidly widening. He had been in England for three years together, 1701 to 1704, and counted Pope, Steele and Addison among his friends. The success of his pamphlet gained him ready access to all Whig circles; but already his confidence in that party was shaken, and he was beginning to meditate that change of sides which has drawn down upon him so much but such unjustifiable obloquy. The true state of the case may easily be collected from his next publications—*The Sentiments of a Church of England Man*, and *On the Reasonableness of a Test* (1708). The vital differences among the friends of the Hanover succession were not political, but ecclesiastical. From this point of view Swift's sympathies were entirely with the Tories. As a minister of the Church he felt his duty and his interest equally concerned in the support of her cause; nor could he fail to discover the inevitable tendency of Whig doctrines, whatever caresses individual Whigs might bestow on individual clergymen, to abase the Establishment as a corporation. He sincerely believed that the ultimate purpose of freethinkers was to escape from moral restraints, and he had an unreasoning antipathy to Scotch Presbyterians and English Dissenters. If Whiggism could be proved to entail Dissent, he was prepared to abandon it. One of his pamphlets, written about this time, contains his recipe for the promotion of religion, and is of itself a sufficient testimony to the extreme materialism of his views. Censorships and penalties are among the means he recommends. His pen was exerted to better purpose in the most consummate example of his irony, the *Argument to prove that the abolishing of Christianity in England may, as things now stand, be attended with some inconveniencies* (1708). About this time, too (November 1707), he produced his best narrative poem, *Baucis and Philemon*, while the next few months witnessed one of the most amusing hoaxes ever perpetrated against the quackery of astrologers. In his *Almanac* for 1707 a Protestant alarmist and plot vaticinator styled John Partridge warned customers against rivals and impostors. This notice attracted Swift's attention, and in January 1708 he issued predictions for the ensuing year by Isaac Bickerstaff, written to prevent the people of England being imposed upon by vulgar almanac makers. In this brochure he predicts solemnly that on the 29th of March at 11 o'clock at night Partridge the almanac maker should infallibly die of a raging fever. On the 30th of March he issued a letter confirming Partridge's sad fate. Grub Street elegies on the almanac maker were hawked about London. Partridge was widely deplored in obituary notices and his name was struck off the rolls at Stationers' Hall. The poor man was obliged to issue a special almanac to assure his clients and the public that he was not dead: he was fatuous enough to add that he was not only alive at the time of writing, but that he was also demonstrably alive on the day when the knave Bickerstaff (a name borrowed by Swift from a sign in Long Acre) asserted that he died of fever. This elicited Swift's most amusing *Vindication of Isaac Bickerstaff Esq.* in April 1709. The laughter thus provoked extinguished the *Predictions* for three years, and in 1715 Partridge died in fact; but the episode left a permanent trace in classic literature, for when in 1709 Steele was to start the *Tatler*, it occurred to him that he could secure the public ear in no surer way than by adopting the name of Bickerstaff.

From February 1708 to April 1709 Swift was in London, urging upon the Godolphin administration the claims of the Irish clergy to the first-fruits and twentieths ("Queen Anne's Bounty"), which brought in about £2500 a year, already granted to their brethren in England.[2] His having been selected for such a commission shows that he was not yet regarded as a deserter from the Whigs, although the ill success of his representations probably helped to make him one. By November 1710 he was again domiciled in London, and writing his *Journal to Stella*, that unique exemplar of a giant's playfulness, "which was written for one person's private pleasure and has had indestructible attractiveness for every one since." In the first pages of this marvellously minute record of a busy life we find him depicting the decline of Whig credit and complaining of the cold reception accorded him by Godolphin, whose penetration had doubtless detected the precariousness of his allegiance. Within a few weeks he had become the lampooner of the fallen treasurer, the bosom friend of Oxford and Bolingbroke, and the writer of the *Examiner*, a journal established as the exponent of Tory views (November 1710). He was now a power in the state, the intimate friend and recognized equal of the first writers of the day, the associate of ministers on a footing of perfect cordiality and familiarity. "We were determined to have you," said Bolingbroke to him afterwards; "you were the only one we were afraid of." He gained his point respecting the Irish endowments; and, by his own account, his credit procured the fortune of more than forty deserving or undeserving clients. The envious but graphic description of his demeanour conveyed to us by Bishop Kennet attests the real dignity of his position no less than the airs he thought fit to assume in consequence. The cheerful, almost jovial, tone of his letters to Stella evinces his full contentment, nor was he one to be moved to gratitude for small mercies. He had it, in fact, fully in his own power to determine his relations with the ministry, and he would be satisfied with nothing short of familiar and ostentatious equality. His advent marks a new era in English political life, the age of public opinion, created indeed by the circumstances of the time, but powerfully fostered and accelerated by him. By a strange but not infrequent irony of fate the most imperious and despotic spirit of his day laboured to enthrone a power which, had he himself been in authority, he would have utterly detested and despised. For a brief time he seemed to resume the whole power of the English press in his own pen and to guide public opinion as he would. His services to his party as writer of the *Examiner*, which he quitted in July 1711, were even surpassed by those which he rendered as the author of telling pamphlets, among which *The Conduct of the Allies and of the Late Ministry, in beginning and carrying on the Present War, and Remarks on the Barrier Treaty* (November and December 1711) hold the first rank. In truth, however, he was lifted by the wave he seemed to command. Surfeited with glory,

[1] The name "Stella" is simply a translation of Esther. Swift may have learned that Esther means "star" from the *Elementa linguae persicae* of John Greaves or from some Persian scholar; but he is more likely to have seen the etymology in the form given from Jewish sources in Buxtorf's *Lexicon*, where the interpretation takes the more suggestive form "Stella Veneris."

[2] The grant of the first-fruits was to be made contingent on a concession from the Irish clergy in the shape of the abolition of the sacramental test. This Swift would not agree to. He ultimately won his point from Harley, and his success marks his open rupture with the Whigs.

which it began, after Malplaquet, to think might be purchased at too heavy a cost, the nation wanted a convenient excuse for relinquishing a burdensome war, which the great military genius of the age was suspected of prolonging to fill his pockets. The Whigs had been long in office. The High Church party had derived great strength from the Sacheverell trial. Swift did not bring about the revolution with which, notwithstanding, he associated his name. There seems no reason to suppose that he was consulted respecting the great Tory strokes of the creation of the twelve new peers and the dismissal of Marlborough (December 1711), but they would hardly have been ventured upon if *The Conduct of the Allies* and the *Examiners* had not prepared the way. A scarcely less important service was rendered to the ministry by his *Letter to the October Club*, artfully composed to soothe the impatience of Harley's extreme followers. He had every claim to the highest preferment that ministers could give him, but his own pride and prejudice in high places stood in his way.

Generous men like Oxford and Bolingbroke cannot have been unwilling to reward so serviceable a friend, especially when their own interest lay in keeping him in England. Harley by this time was losing influence and was becoming chronically incapable of any sustained effort. Swift was naturally a little sore at seeing the see of Hereford slipping through his fingers. He had already lost Waterford owing to the prejudice against making the author of the *Tale of a Tub* a bishop, and he still had formidable antagonists in the archbishop of York, whom he had scandalized, and the duchess of Somerset, whom he had satirized. Anne was particularly amenable to the influence of priestly and female favourites, and it must be considered a proof of the strong interest made for Swift that she was eventually persuaded to appoint him to the deanery of St Patrick's, Dublin, vacant by the removal of Bishop Sterne to Dromore. It is to his honour that he never speaks of the queen with resentment or bitterness. In June 1713 he set out to take possession of his dignity, and encountered a very cold reception from the Dublin public. The dissensions between the chiefs of his party speedily recalled him to England. He found affairs in a desperate condition. The queen's demise was evidently at hand, and the same instinctive good sense which had ranged the nation on the side of the Tories, when Tories alone could terminate a fatiguing war, rendered it Whig when Tories manifestly could not be trusted to maintain the Protestant succession. In any event the occupants of office could merely have had the choice of risking their heads in an attempt to exclude the elector of Hanover, or of waiting patiently till he should come and eject them from their posts; yet they might have remained formidable could they have remained united. To the indignation with which he regarded Oxford's refusal to advance him in the peerage the active St John added an old disgust at the treasurer's pedantic and dilatory formalism, as well as his evident propensity, while leaving his colleague the fatigues, to engross for himself the chief credit of the administration. Their schemes of policy diverged as widely as their characters: Bolingbroke's brain teemed with the wildest plans, which Oxford might have more effectually discountenanced had he been prepared with anything in their place. Swift's endeavours after an accommodation were as fruitless as unremitting. His mortification was little likely to temper the habitual virulence of his pen, which rarely produced anything more acrimonious than the attacks he at this period directed against Burnet and his former friend Steele. One of his pamphlets against the latter (*The Public Spirit of the Whigs set forth in their Generous Encouragement of the Author of the Crisis*, 1714) was near involving him in a prosecution, some invectives against the Scottish peers having proved so exasperating to Argyll and others that they repaired to the queen to demand the punishment of the author, of whose identity there could be no doubt, although, like all Swift's writings, except the *Proposal for the Extension of Religion*, the pamphlet had been published anonymously. The immediate withdrawal of the offensive passage, and a sham prosecution instituted against the printer, extricated Swift from his danger.

Meanwhile the crisis had arrived, and the discord of Oxford and Bolingbroke had become patent to all the nation. Foreseeing, as is probable, the impending fall of the former, Swift retired to Upper Letcombe, in Berkshire, and there spent some weeks in the strictest seclusion. This leisure was occupied in the composition of his remarkable pamphlet, *Some Free Thoughts on the Present State of Affairs*, which indicates his complete conversion to the bold policy of Bolingbroke. The utter exclusion of Whigs as well as Dissenters from office, the remodelling of the army, the imposition of the most rigid restraints on the heir to the throne—such were the measures which, by recommending, Swift tacitly admitted to be necessary to the triumph of his party. If he were serious, it can only be said that the desperation of his circumstances had momentarily troubled the lucidity of his understanding; if the pamphlet were merely intended as a feeler after public opinion, it is surprising that he did not perceive how irretrievably he was ruining his friends in the eyes of all moderate men. Bolingbroke's daring spirit, however, recoiled from no extreme, and, fortunately for Swift, he added so much of his own to the latter's MS. that the production was first delayed and then, upon the news of Anne's death, immediately suppressed. This incident but just anticipated the revolution which, after Bolingbroke had enjoyed a three days' triumph over Oxford, drove him into exile and prostrated his party, but enabled Swift to perform the noblest action of his life. Almost the first acts of Bolingbroke's ephemeral premiership were to order him a thousand pounds from the exchequer and despatch him the most flattering invitations. The same post brought a letter from Oxford, soliciting Swift's company in his retirement; and, to the latter's immortal honour, he hesitated not an instant in preferring the solace of his friend to the offers of St John. When, a few days afterwards, Oxford was in prison and in danger of his life, Swift begged to share his captivity; and it was only on the offer being declined that he finally directed his steps towards Ireland, where he was very ill received. The draft on the exchequer was intercepted by the queen's death.

These four busy years of Swift's London life had not been entirely engrossed by politics. First as the associate of Steele, with whom he quarrelled, and of Addison, whose esteem for him survived all differences, afterwards as the intimate comrade of Pope and Arbuthnot, the friend of Congreve and Atterbury, Parnell and Gay, he entered deeply into the literary life of the period. He was treasurer and a leading member of the Brothers, a society of wits and statesmen which recalls the days of Horace and Maecenas. He promoted the subscription for Pope's *Homer*, contributed some numbers to the *Tatler*, *Spectator*, and *Intelligencer*, and joined with Pope and Arbuthnot in establishing the Scriblerus Club, writing *Martinus Scriblerus*, his share in which can have been but small, as well as *John Bull*, where the chapter recommending the education of all blue-eyed children in depravity for the public good must surely be his. His miscellanies, in some of which his satire made the nearest approach perhaps ever made to the methods of physical force, such as *A Meditation upon a Broomstick*, and the poems *Sid Hamet's Rod*, *The City Shower*, *The Windsor Prophecy*, *The Prediction of Merlin*, and *The History of Vanbrugh's House*, belong to this period. A more laboured work, his *Proposal for Correcting, Improving and Ascertaining the English Tongue* (1712), in a letter to Harley, suggesting the regulation of the English language by an academy, is chiefly remarkable as a proof of the deference paid to French taste by the most original English writer of his day. His *History of the Four Last Years of the Reign of Queen Anne* is not on a level with his other political writings. To sum up the incidents of this eventful period of his life, it was during it that he lost his mother, always loved and dutifully honoured, by death; his sister had been estranged from him some years before by an imprudent marriage, which, though making her a liberal allowance, he never forgave.

The change from London to Dublin can seldom be an agreeable one. To Swift it meant for the time the fall from unique authority to absolute insignificance. All share in the administration of even Irish affairs was denied him; every politician shunned him; and his society hardly included a single author or wit. He "continued in the greatest privacy" and "began to think of death." At a later period he talked of "dying of rage, like a poisoned rat in a hole"; for some time, however, he was buoyed up by feeble hopes of a restoration to England. So late as 1726 he was in England making overtures to Walpole, but he had no claim on ministerial goodwill, and as an opponent he had by that time done his worst. By an especial cruelty of fate, what should have been the comfort became the bane of his existence. We have already mentioned his invitation of Esther Johnson and Mrs Dingley to Ireland. Both before and after his elevation to the deanery of St Patrick's these ladies continued to reside near him, and superintended his household during his absence in London. He had offered no obstacle in 1704 to a match proposed for Stella to Dr William Tisdall of Dublin, and, with his evident delight in the society of the dark-haired, bright-eyed, witty beauty—a model, if we may take his word, of all that woman should be—it seemed unaccountable that he did not secure it to himself by the expedient of matrimony. A constitutional infirmity has been suggested as the reason, and the conjecture derives support from several peculiarities in his writings. But, whatever the cause, his conduct proved none the less the fatal embitterment of his life and Stella's and yet another's. He had always been unlucky in his relations with the fair sex. In 1695 he had idealized "Varina." Varina was avenged by Vanessa, who pursued Swift to far other purpose. Esther Vanhomrigh (b. February 14, 1690), the daughter of a Dublin merchant of Dutch origin, who died in 1703 leaving £16,000, had become known to Swift at the height of his political influence. He lodged close to her mother, was introduced to the family by Sir A. Fountaine in 1708 and became an intimate of the house. Vanessa insensibly became his pupil, and he insensibly became the object of her impassioned affection. Her letters reveal a spirit full of ardour and enthusiasm, and warped by that perverse bent which leads so many women to prefer a tyrant to a companion. Swift, on the other hand, was devoid of passion. Of friendship, even of tender regard, he was fully capable, but not of love. The spiritual realm, whether in divine or earthly things, was a region closed to him, where he had never set foot. As a friend he must have greatly preferred Stella to Vanessa. Marriage was out of the question with him, and, judged in the light of Stella's dignity and womanliness, this ardent and unreasoning display of passion was beyond comprehension. But Vanessa assailed him on a very weak side. The strongest of all his instincts was the thirst for imperious domination. Vanessa hugged the fetters to which Stella merely submitted. Flattered to excess by her surrender, yet conscious of his binding obligations and his real preference, he could neither discard the one beauty nor desert the other. It is humiliating to human strength and consoling to human weakness to find the Titan behaving like the least resolute of mortals, seeking refuge in temporizing, in evasion, in fortuitious circumstance. He no doubt trusted that his removal to Dublin would bring relief, but here again his evil star interposed. Vanessa's mother died (1714), and she followed him to Ireland, taking up her abode at Celbridge within ten miles of Dublin. Unable to marry Stella without destroying Vanessa, or to openly welcome Vanessa without destroying Stella, he was thus involved in the most miserable embarrassment; he continued to temporize. Had the solution of marriage been open Stella would undoubtedly have been Swift's choice. Some mysterious obstacle intervened. It was rumoured at the time that Stella was the natural daughter of Temple, and Swift himself at times seems to have been doubtful as to his own paternity. There is naturally no evidence for such reports, which may have been fabrications of the anti-deanery faction in Dublin. From the same source sprang the report of Swift's marriage to Stella by Bishop Ashe in the deanery garden at Clogher in the summer of 1716. The ceremony, it is suggested, may have been extorted by the jealousy of Stella and have been accompanied by the express condition on Swift's side that the marriage was never to be avowed. The evidence is by no means complete and has never been exhaustively reviewed. John Lyon, Swift's constant attendant from 1735 onwards, disbelieved the story. It was accepted by the early biographers, Deane Swift, Orrery, Delany and Sheridan; also by Johnson, Scott, Dr Garnett, Craik, Dr Bernard and others. The arguments against the marriage were first marshalled by Monck Mason in his *History of St Patrick's*, and the conjecture, though plausible, has failed to convince Forster, Stephen, Aitken, Hill, Lane Poole and Churton Collins. Never more than a nominal wife at most, the unfortunate Stella commonly passed for his mistress till the day of her death (in her will she writes herself *spinster*), bearing her doom with uncomplaining resignation, and consoled in some degree by unquestionable proofs of the permanence of his love, if his feeling for her deserves the name. Meanwhile his efforts were directed to soothe Miss Vanhomrigh, to whom he addressed *Cadenus* [*Decanus*] *and Vanessa*, the history of their attachment and the best example of his serious poetry, and for whom he sought to provide honourably in marriage, without either succeeding in his immediate aim or in thereby opening her eyes to the hopelessness of her passion. In 1720, on what occasion is uncertain, he began to pay her regular visits. Sir Walter Scott found the Abbey garden at Celbridge still full of laurels, several of which she was accustomed to plant whenever she expected Swift, and the table at which they had been used to sit was still shown. But the catastrophe of her tragedy was at hand. Worn out with his evasions, she at last (1723) took the desperate step of writing to Stella or, according to another account, to Swift himself, demanding to know the nature of the connexion with him, and this terminated the melancholy history as with a clap of thunder. Stella sent her rival's letter to Swift, and retired to a friend's house. Swift rode down to Marley Abbey with a terrible countenance, petrified Vanessa by his frown, and departed without a word, flinging down a packet which only contained her own letter to Stella. Vanessa died within a few weeks. She left the poem and correspondence for publication. The former appeared immediately, the latter was suppressed until it was published by Sir Walter Scott.

Five years afterwards Stella followed Vanessa to the grave. The grief which the gradual decay of her health evidently occasioned Swift is sufficient proof of the sincerity of his attachment, as he understood it. It is a just remark of Thackeray's that he everywhere half-consciously recognizes her as his better angel, and dwells on her wit and her tenderness with a fondness he never exhibits for any other topic. On the 28th of January 1728, she died, and her wretched lover sat down the same night to record her virtues in language of unsurpassed simplicity, but to us who know the story more significantly for what it conceals than for what it tells. A lock of her hair is preserved, with the inscription in Swift's handwriting, most affecting in its apparent cynicism, "Only a woman's hair!" "Only a woman's hair," comments Thackeray; "only love, only fidelity, purity, innocence, beauty, only the tenderest heart in the world stricken and wounded, and passed away out of reach of pangs of hope deferred, love insulted and pitiless-desertion; only that lock of hair left, and memory, and remorse, for the guilty, lonely wretch, shuddering over the grave of his victim." The more unanswerable this tremendous indictment appears upon the evidence the greater the probability that the evidence is incomplete. *Tout comprendre c'est tout pardonner.*

Between the death of Vanessa and the death of Stella came the greatest political and the greatest literary triumph of Swift's life. He had fled to Ireland a broken man, to all appearance politically extinct; a few years were to raise him once more to the summit of popularity, though power was for ever denied him. Consciously or unconsciously he first taught the Irish to rely upon themselves and for many generations his name was the most universally popular in the country. With his fierce hatred of what he recognized as injustice, it was impossible that he should not feel exasperated at the gross misgovernment of Ireland for the supposed benefit of England, the systematic exclusion of Irishmen from places of honour and profit, the spoliation of the country by absentee landlords, the deliberate discouragement of Irish trade and manufactures. An Irish patriot in the strict sense of the term he was not; he was proud of being an Englishman, who had been accidentally "dropped in Ireland"; he looked upon the indigenous population as conquered savages; but his pride and sense of equity alike revolted against the stay-at-home Englishmen's contemptuous treatment of their own garrison, and he delighted in finding a point in which the triumphant faction was still vulnerable. His *Proposal for the Universal Use of Irish Manufactures*, published anonymously in 1720, urging the Irish to disuse English goods, became the subject of a prosecution, which at length had to be dropped. A greater opportunity was at hand. One of the chief wants of Ireland in that day, and for many a day afterwards, was that of small currency adapted to the daily transactions of life. Questions of coinage occupy a large part of the correspondence of the primate, Archbishop Boulter, whose anxiety to deal rightly with the matter is evidently very real and conscientious. There is no reason to think that the English ministry wished otherwise; but secret influences were at work, and a patent for supplying Ireland with a coinage of copper halfpence was accorded to William Wood on such terms that the profit accruing from the difference between the intrinsic and the nominal value of the coins, about 40%, was mainly divided between him and George I.'s favourite duchess of Kendal, by whose influence Wood had obtained the privilege. Swift now had his opportunity, and the famous six letters signed M. B. Drapier (April to Dec. 1724) soon set Ireland in a flame. Every effort was used to discover, or rather to obtain legal evidence against, the author, whom, Walpole was assured, it would then have taken ten thousand men to apprehend. None could be procured; the public passion swept everything before it; the patent was cancelled; Wood was compensated by a pension; Swift was raised to a height of popularity which he retained for the rest of his life; and the only real sufferers were the Irish people, who lost a convenience so badly needed that they might well have afforded to connive at Wood's illicit profits. Perhaps, however, it was worth while to teach the English ministry that not everything could be done in Ireland. Swift's pamphlets, written in a style more level with the popular intelligence than even his own ordinary manner, are models alike to the controversialist who aids a good cause and to him who is burdened with a bad one. The former may profit by the study of his marvellous lucidity and vehemence, the latter by his sublime audacity in exaggeration and the sophistry with which he involves the innocent halfpence in the obloquy of the nefarious patentee.

The noise of the *Drapier Letters* had hardly died away when Swift acquired a more durable glory by the publication of *Travels Into Several Remote Nations of the World*, in four parts. By Lemuel Gulliver, first a surgeon and then a captain of several ships (Benjamin Motto, October 1726). The first hint came to him at the meetings of the Scriblerus Club in 1714, and the work was well advanced, it would seem, by 1720. Allusions show that it was circulated privately for a considerable period before its actual (anonymous) publication, on the 28th of October 1726. Pope arranged that Erasmus Lewis should act as literary agent in negotiating the manuscript. Swift was afraid of the reception the book would meet with, especially in political circles. The keenness of the satire on courts, parties and statesmen certainly suggests that it was planned while Swift's disappointments as a public man were still rankling and recent. It is Swift's peculiar good fortune that his book can dispense with the interpretation of which it is nevertheless susceptible, and may be equally enjoyed whether its inner meaning is apprehended or not. It is so true, so entirely based upon the facts of human nature, that the question what particular class of persons supplied the author with his examples of folly or misdoing, however interesting to the commentator, may be neglected by the reader. It is also fortunate for him that in three parts out of the four he should have entirely missed "the chief end I propose to myself, to vex the world rather than divert it." The world, which perhaps ought to have been vexed, chose rather to be diverted; and the great satirist literally strains his power *ut pueris placeat*. Few books have added so much to the innocent mirth of mankind of the first two parts of Gulliver; the misanthropy is quite overpowered by the fun. The third part, equally masterly in composition, is less felicitous in invention; and in the fourth Swift has indeed carried out his design of vexing the world at his own cost. Human nature indignantly rejects her portrait in the Yahoo as a gross libel, and the protest is fully warranted. An intelligence from a superior sphere, bound on a voyage to the earth, might actually have obtained a fair idea of average humanity by a preliminary call at Lilliput or Brobdingnag, but not from a visit to the Yahoos. While *Gulliver* is infinitely the most famous and popular of Swift's works, it exhibits no greater powers of mind than many others. The secret of success, here as elsewhere, is the writer's marvellous imperturbability in paradox, his teeming imagination and his rigid logic. Grant his premises, and all the rest follows; his world may be turned topsy-turvy, but the relative situation of its contents is unchanged. The laborious attempts that have been made, particularly in Germany, to affiliate the *Travels* only serve to bring Swift's essential originality into stronger relief. He had naturally read Lucian and Rabelais—possibly *Crusoe* and the *Arabian Nights*. He had read as a young man the lunary adventure of Bishop Wilkins, Bishop Godwin and Cyrano de Bergerac. He had read contemporary accounts of Peter the Wild Boy, the *History of Sevarambes* by D'Alais (1677) and Foligny's *Journey of Jacques Sadeut to Australia* (1693). He may have read Joshua Barnes's description of a race of "Pygmies" in his *Gerania* of 1675. He copied the account of the storm in the second voyage almost literally from Sturmy's *Compleat Mariner*. Travellers' tales were deliberately embalmed by Swift in the amber of his irony. Something similar was attempted by Raspe in his *Munchausen* sixty years later.

Swift's grave humour and power of enforcing momentous truth by ludicrous exaggeration were next displayed in his *Modest Proposal for Preventing the Children of Poor People from being a Burden to their Parents or the Country*, by fattening and eating them (1729), a parallel to the *Argument against Abolishing Christianity*, and as great a masterpiece of tragic as the latter is of comic irony. The *Directions to Servants* (first published in 1745) in like manner derive their overpowering comic force from the imperturbable solemnity with which all the misdemeanours that domestics can commit are enjoined upon them as duties. The power of minute observation displayed is most remarkable, as also in *Polite Conversation* (written in 1731, published in 1738), a surprising assemblage of the vulgarities and trivialities current in ordinary talk. As in the *Directions*, the satire, though cutting, is good-natured, and the piece shows more animal spirits than usual in Swift's latter years. It was a last flash of gaiety. The attacks of giddiness and deafness to which he had always been liable increased upon him. Already in 1721 he complains that the buzzing in his ears disconcerts and confounds him. After the *Directions* he writes little beyond occasional verses, not seldom indecent and commonly trivial. He sought refuge from inferior society often in nonsense, occasionally in obscenity. An exception must be made in the case of the delightful *Hamilton's Bawn*, and still more of the verses on his own death (1731), one of the most powerful and also one of the saddest of his poems. In *The Legion Club* of 1736 he composed the fiercest of all his verse satires. He hated the Irish parliament for its lethargy and the Irish bishops for their interference. He fiercely opposed Archbishop Boulter's plans for the reform of the Irish currency, but admitted that his real objection was sentimental: the coins should be struck as well as circulated in Ireland. His exertions in repressing robbery and mendicancy were strenuous and successful. His popularity remained as great as ever (he received the freedom of Dublin in 1729), and, when he was menaced by the bully Bettesworth, Dublin rose as one man to defend him. He governed his cathedral with great strictness and conscientiousness, and for years after Stella's death continued to hold a miniature court at the deanery. But his failings of mind were exacerbated by his bodily infirmities; he grew more and more whimsical and capricious, morbidly suspicious and morbidly parsimonius; old friends were estranged or removed by death, and new friends did not come forward in their place. For many years, nevertheless, he maintained a correspondence with Pope and Bolingbroke, and with Arbuthnot and Gay until their deaths, with such warmth as to prove that an ill opinion of mankind had not made him a misanthrope, and that human affection and sympathy were still very necessary to him. The letters become scarcer and scarcer with the decay of his faculties; at last, in 1740, comes one to his kind niece, Mrs Whiteway, of heartrending pathos:—

"I have been very miserable all night, and to-day extremely deaf and full of pain. I am so stupid and confounded that I cannot express the mortification I am under both of body and mind. All I can say is that I am not in torture; but I daily and hourly expect it. Pray let me know how your health is and your family: I hardly understand one word I write. I am sure my days will be very few; few and miserable they must be. I am, for those few days, yours entirely—JONATHAN SWIFT.

"If I do not blunder, it is Saturday, July 26, 1740.

"If I live till Monday I shall hope to see you, perhaps for the last time."

Account book entries continue until 1742.

In March 1742 it was necessary to appoint guardians of Swift's person and estate. In September of the same year his physical malady reached a crisis, from which he emerged a helpless wreck, with faculties paralysed rather than destroyed—"He never talked nonsense or said a foolish thing." The particulars of his case have been investigated by Dr Bucknill and Sir William Wilde, who have proved that he suffered from nothing that could be called mental derangement until the "labyrinthine vertigo" from which he had suffered all his life, and which he erroneously attributed to a surfeit of fruit, produced paralysis, "a symptom of which was the not uncommon one of aphasia, or the automatic utterance of words ungoverned by intention. As a consequence of that paralysis, but not before, the brain, already weakened by senile decay, at length gave way, and Swift sank into the dementia which preceded his death." In other words he retained his reason until in his 74th year he was struck down by a new disease in the form of a localized left-sided apoplexy or cerebral softening. Aphasia due to the local trouble and general decay then progressed rapidly together, and even then at 76, two more years were still to elapse before "he exchanged the sleep of idiocy for the sleep of death." The scene closed on the 19th of October 1745. With what he himself described as a satiric touch, his fortune was bequeathed to found a hospital for idiots and lunatics, now an important institution, as it was in many respects a pioneer bequest. He was interred in his cathedral at midnight on the 22nd of October, in the same coffin as Stella, with the epitaph, written by himself, "Hic depositum est corpus Jonathan Swift, S.T.P., hujus ecclesiae cathedralis decani; ubi saeva indignatio cor ulterius lacerare nequit. Abi, viator, et imitare, si poteris, strenuum pro virili libertatis vindicem."

The stress which Swift thus laid upon his character as an assertor of liberty has hardly been ratified by posterity, which has apparently neglected the patriot for the genius and the wit. Not unreasonably; for if half his patriotism sprang from an instinctive hatred of oppression, the other half was disappointed egotism. He utterly lacked the ideal aspiration which the patriot should possess: his hatred of villany was far more intense than his love of virtue. The same cramping realism clings to him everywhere beyond the domain of politics—in his religion, in his fancies, in his affections. At the same time, it is the secret of his wonderful concentration of power: he realizes everything with such intensity that he cannot fail to be impressive. Except in his unsuccessful essay in history, he never, after the mistake of his first Pindaric attempts, strays beyond his sphere, never attempts what he is not qualified to do, and never fails to do it. His writings have not one literary fault except their occasional looseness of grammar and their frequent indecency. Within certain limits, his imagination and invention are as active as those of the most creative poets. As a master of humour, irony and invective he has no superior; his reasoning powers are no less remarkable within their range, but he never gets beyond the range of an advocate. Few men of so much mental force have had so little genius for speculation, and he is constantly dominated by fierce instincts which he mistakes for reasons. As a man the leading note of his character is the same —strength without elevation. His master passion is imperious pride—the lust of despotic dominion. He would have his superiority acknowledged, and cared little for the rest. Place and profit were comparatively indifferent to him; he declares that he never received a farthing for any of his works except *Gulliver's Travels*, and that only by Pope's management; and he had so little regard for literary fame that he put his name to only one of his writings. Contemptuous of the opinion of his fellows, he hid his virtues, paraded his faults, affected some failings from which he was really exempt, and, since his munificent charity could not be concealed from the recipients, laboured to spoil it by gratuitous surliness. Judged by some passages of his life he would appear a heartless egotist, and yet he was capable of the sincerest friendship and could never dispense with human sympathy. Thus an object of pity as well as awe, he is the most tragic figure in our literature—the only man of his age who could be conceived as affording a groundwork for one of the creations of Shakespeare. "To think of him," says Thackeray, "is like thinking of the ruin of a great empire." Nothing finer or truer could be said.

Swift inoculated the Scriblerus Club with his own hatred of pedantry, cant and circumlocution. His own prose is the acme of incisive force and directness. He uses the vernacular with an economy which no other English writer has rivalled. There is a masculinity about his phrases which makes him as clear to the humblest capacity as they are capable of being made to anyone. Ironist as he is, there is no writer that ever wrote whose meaning is more absolutely unmistakable. He is the grand master of the order of plain speech. His influence, which grew during the 18th century in spite of the depreciation of Dr Johnson, has shared in the eclipse of the Queen Anne wits which began about the time of Jeffrey. Yet as the author of *Gulliver* he is still read all over the world, while in England discipleship to Swift is recognized as one of the surest passports to a prose style. Among those upon whom Swift's influence has been most discernible may be mentioned Chesterfield, Smollett, Cobbett, Hazlitt, Scott, Borrow, Newman, Belloc.

AUTHORITIES.—Among the authorities for Swift's life the first place is still of course occupied by his own writings, especially the fragment of autobiography now at Trinity College, Dublin, and his Correspondence, which still awaits an authoritative annotated edition. The most important portion is contained in the *Journal to Stella*. Twenty-five of these letters on Swift's death became the property of Dr Lyon. Hawkesworth bought them for his 1766 edition of the *Works* and eventually gave them to the British Museum. Forty additional letters were published by Dean Swift in 1768 (of these only No. 1 survives in the British Museum). Sheridan brought out the complete *Journal* in 1784 in a mangled form, but the text has as far as possible been restored by modern editors such as Forster, Rylands and Aitken. A full annotated edition is in course of preparation by H. Spencer Scott. The Vanessa correspondence was used by Sheridan, but first published in full by Sir Walter Scott, and Swift's letters to his friend Knightley Chetwode of Woodbrook between 1714 and 1731, over fifty in number, were first issued by Dr Birkbeck Hill in 1899. The more or less contemporary lives of Swift, most of which contain a certain amount of apocrypha, are those of Lord Orrery (1751); Dr Delany's *Observations on Orrery* (1754); Dean Swift's *Essay upon the Life of Swift* (1755); and Thomas Sheridan's *Life* (of 1785). Dr. Hawkesworth, in the life prefixed to his edition of the *Works* in 1755, adds little of importance. Dr Johnson's *Life* is marred by manifest prejudice. Dr Barrett produced an *Essay upon the Early Life* of some value (in 1808). Six years later came the useful biography of Sir Walter Scott, and (in 1819) appeared the elaborate *Life* by W. Monck Mason in the form of an appendix to his ponderous *History of St Patrick's*. A new epoch of investigation was inaugurated by John Forster, who began a new scrutiny of the accumulated material and published his first volume in 1875. Invaluable in many respects, it exhibited the process as well as the result of biography, and never got beyond 1711. The *Life* by Sir Henry Craik (1882 and reissues) now holds the field. Valuable monographs have been produced by Sir Leslie Stephen (Men of Letters and the Memoirs, in the *Dict. Nat. Biog.*), by Thackeray, in his *English Humourists*, by W. R. Wilde, in his *Closing Years of Dean Swift's*

Life, by Lecky, in his *Leaders of Public Opinion*, by G. P. Moriarty, J. Churton Collins (1893), Max Simon (1893), Henriette Cordelet (1907) and Sophie Shilleto Smith (1910). The anecdotes of Swift related in Spence, *Laetitia Pilkington*, Wilson's *Swiftiana*, Delany's *Autobiography*, &c., though often amusing, can hardly be accepted as authentic.

The collective editions of Dr Hawkesworth (various issues, 1755–1779), T. Sheridan (1785), John Nichols (1801, 1804, 1808), Scott (1814 and 1821) and Roscoe (2 vols., 1849) have been in most respects superseded by the edition in Bohn's Standard Library in fourteen volumes (including the two subsequently issued volumes of *Poems*) (1897–1910); arranged as follows: I. Biog. Introduction by W. E. H. Lecky; *Tale of a Tub*; *Battle of the Books*; *Critical Essay upon the Faculties of the Mind*; *The Bickerstaff Pamphlets*, &c., ed. Temple Scott. II. *Journal to Stella*, ed. F. Ryland (two portraits of Stella). III. and IV. *Writings on Religion and the Church*, ed. Temple Scott. V. *Historical and Political Tracts—English*, ed. Temple Scott. VI. *Historical and Political Tracts—Irish*, ed. Temple Scott. VII. The *Drapier's Letters*, ed. Temple Scott. VIII. and XI. Literary Essays, including *Gulliver's Travels* (ed. G. R. Dennis); *A Proposal for Correcting, Improving and Ascertaining the English Tongue*; *Hints towards an Essay on Conversation*; *Character*; *Directions to Servants*; and *Autobiographical Fragment*, ed. Temple Scott. IX. Contributions to the *Examiner*, *Tatler*, *Spectator*, &c., ed. Temple Scott. X. Historical Writings, including the *Four Last Years*; *Abstract of English History*; and *Remarks on Burnet*, ed. Temple Scott. XII. Essays on the Portraits, &c., Bibliography by W. Spencer Jackson, and Index. Twelve portraits of Swift are included in the work, in addition to two portraits of Stella and one of Vanessa. XIII. and XIV. Poems, ed. W. Ernst Browning.

Translations and editions of *Gulliver's Travels* have been numerous. "Valuable Notes for a Bibliography of Swift" were published by Dr S. Lane Poole in *The Bibliographer* (November 1884).

(R. G.; T. Se.)

SWIFT, a bird so called from the extreme speed of its flight, which apparently exceeds that of any other British species, the *Hirundo apus* of Linnaeus and *Cypselus apus* or *murarius* of modern ornithologists. Swifts were formerly associated with swallows (*q.v.*) in classification, but whilst the latter are true Passeres, it is now established that swifts are Coraciiform birds (see Birds) and the sub-order *Cypseli* has been formed to include them and their nearest allies, the humming-birds. The four toes are all directed forwards, whereas in the Passeres the hallux is directed backwards and by opposing the other three makes the foot a grasping organ. In the swifts, moreover, the middle and outer digits have only three joints and the metatarsi and even the toes may be feathered. Swifts are divided into three sub-families: *Macropteryginae*, the true swifts, of tropical Asia, which form a nest gummed by saliva to branches of trees; *Chaeturinae*, building in rocks or houses, and with an almost world-wide range: it includes *Chaetura palagica*, the "chimney-swallow" of the United States, *Collocalia fuciphaga* which obtained its specific name from the erroneous idea that its edible nests were formed by partly digested seaweed; *Cypselinae*, also world-wide and containing *Cypselus apus*, the common European swift. All the swifts are migratory. Well known as a summer visitor throughout the greater part of Europe, the swift is one of the latest to return from Africa, and its stay in the country of its birth is of the shortest, for it generally disappears from England very early in August, though occasionally to be seen for even two months later.

The swift commonly chooses its nesting-place in holes under the eaves of buildings, but a crevice in the face of a quarry, or even a hollow tree, will serve it with the accommodation it requires. This, indeed, is not much, since every natural function except sleep, oviposition and incubation, is performed on the wing, and the easy evolutions of this bird in the air, where it remains for hours together, are the admiration of all who witness them. Though considerably larger than a swallow, it can be recognized at a distance less by its size than by its peculiar shape. The head scarcely projects from the anterior outline of the pointed wings, which form an almost continuous curve, at right angles to which extend the body and tail, resembling the handle of the crescentic cutting-knife used in several trades, while the wings represent the blade. The mode of flight of the two birds is also unlike, that of the swift being much more steady, and, rapid as it is, ordinarily free from jerks. The whole plumage, except a greyish white patch under the chin, is a sooty black, but glossy above. Though its actual breeding-places are by no means numerous, its extraordinary speed and discursive habits make the swift widely distributed; and throughout England scarcely a summer's day passes without its being seen in most places. A larger species, *C. melba* or *C. alpinus*, with the lower parts dusky white, which has its home in many of the mountainous parts of central and southern Europe, has several times been observed in Britain, and two examples of a species of a very distinct genus *Chaetura*, which has its home in northern Asia, but regularly emigrates thence to Australia, have been obtained in England (*Proc. Zool. Soc.*, 1880, p. 1).

Among other peculiarities the swifts, as long ago described (probably from John Hunter's notes) by Sir E. Home (*Phil. Trans.* 1817, pp. 332 et seq., pl. xvi.), are remarkable for the development of their salivary glands, the secretions of which serve in most species to glue together the materials of which the nests are composed, and in the species of the genus *Collocalia* form almost the whole substance of the structure. These are the "edible" nests so eagerly sought by Chinese epicures as an ingredient for soup. These remarkable nests consist essentially of mucus, secreted by the salivary glands above mentioned, which dries and looks like isinglass. Their marketable value depends on their colour and purity, for they are often intermixed with feathers and other foreign substances. The swifts that construct these "edible" nests form a genus *Collocalia*, with many species; but they inhabit chiefly the islands of the Indian Ocean from the north of Madagascar eastward, as well as many of the tropical islands of the Pacific so far as the Marquesas—one species occurring in the hill-country of India. They breed in caves, to which they resort in great numbers, and occupy them jointly and yet alternately with bats—the mammals being the lodgers by day and the birds by night. (A.N.)

SWIMMING (from "swim," A.S. *swimman*, the root being common in Teutonic languages), the action of self-support and self-propulsion on or in water; though used by analogy of inanimate objects, the term is generally connected with animal progression and specially with the art of self-propulsion on water as practised by man. Natation (the synonym derived from Lat. *natare*) is one of the most useful of the physical acquirements of man. There have been cases in which beginners have demonstrated some ability in the art upon their first immersion in deep water, but generally speaking it is an art which has to be acquired. For many years Great Britain held the supremacy in this particular form of athletics, but continental, Australian and American swimmers have so much improved and have developed such speedy strokes, that the claim can no longer be maintained. English swimmers have, however, the satisfaction of knowing that in a great measure through them has come about the very great interest which is now taken in the teaching of swimming throughout the world, and more particularly on the continent of Europe, where they have made frequent tours and given instructive displays of swimming, life-saving (see Drowning), and water polo (*q.v.*); the latter a water game entirely British in its origin.

The teaching of swimming has been taken up in schools, and where the work is well done it is customary to use a form of land drill so as to impress upon the pupils some idea of the motions which have to be made in order to progress through the water. This drill is the preliminary practice to the teaching of the *breast stroke*. This stroke is about the most useful of all the known forms of swimming, more particularly when any one is thrown overboard in clothes; and though speed swimmers look upon it as obsolete, it is undoubtedly the best for a long-distance swim, such as across the English Channel, or other similar feats. A knowledge of it, as well as of the *back stroke*, is essential to the effective saving of life.

When learning the *breast stroke*, the first thing to avoid is undue haste and rapidity in the movements. It is this fault, probably born of nervousness, which causes many to aver that though eager to do so, they have never been able to learn to swim. Rapid action of the arms only exhausts the learner, whose breathing then becomes hurried and irregular, and as a consequence he fails to preserve the buoyancy necessary for carrying him along the surface. When starting for the first stroke the beginner should draw the elbows nearly to the side, at the same time bringing up the forearm and hands to the front of the chest with the palms of the hands downwards near to the surface of the water, the fingers being extended and closed and the forefingers and thumbs nearly touching. The hands are then pushed forward in front of the body to the full extent of the arms, the palms of the hands are turned slightly outwards, and the arms swept round until in a right angle with the shoulders, when the elbows are dropped and the hands come up in front of the chest for the next stroke. The arms should not be kept rigid, but allowed to work gracefully. As the arms are swept backwards the legs are drawn up, the knees being turned outward to the right and left and the heels nearly touching. The legs are then kicked outward and swept round as the arms are being pushed forward to their fullest extent, a "flip" being given with each of the feet, which must be kept loose at the ankles and in the same position as when standing. All beginners have the great fault of trying to make the limbs too rigid, thereby causing stiffness and possibly cramp. Another difficulty with them is the question of breathing, but if the learner will remember to inhale when making each backward sweep of the arms, much of the difficulty usually experienced at the start will be overcome. Expiration should be carried out during the other portion of each stroke. The important thing is to keep the body as level along the surface as possible, and at the same time get regular and natural breathing. The holding of the breath for two or three strokes will exhaust the beginner more than anything else.

A knowledge of the *back stroke* can easily be acquired by those who are able to swim on the breast, for the leg action is very similar and the principles relating to the use of the arms are almost the same. The arms, instead of being moved through the water, are lifted in the air and carried out to beyond the head with the palms upwards. The palms are then slightly turned and the arms swept round. Just as this action is being made the legs are drawn up as in the breast stroke, the body being allowed to travel on with the force of the kick as the arms are extended beyond the head. The great difficulty that a back swimmer has to contend with in open water is that of steering, and the best way to overcome it is to take an object for a guide before starting and hold the head slightly to the side so as to steer by it.

At one time the *side stroke* was the great racing stroke; the body being placed on the side, the upper arm worked from the head to the upper side of the body, the lower arm taken downwards through the water to the underside of the body and a scissor-like kick made with the legs; but this has now been generally given up in favour of the *over-arm, trudgen* and *crawl strokes*.

In the *over-arm* stroke the body is usually turned on the right side.. At the start the lower arm is pulled downwards towards the hips, the fingers being kept closed and the hand flat, so as to present a large surface to the water. When the stroke is finished the hand is turned quickly palm upwards, so that together with the lower part of the arm it cuts the water sideways, the arm being almost bent double. Then, as it is shot forward, the hand is gradually turned from palm upwards to palm downwards, until, when it arrives at its position beyond the head, it is ready for the next stroke. The recovery and the pull ought to be effected as quickly as possible. The upper arm stroke is started when the downward stroke of the under or right arm is finished. It is started in front of the forehead, the arm being slightly bent and the fingers pointing downwards. The hand is pulled past the face and chest with the arm bent at right angles and swept back in front of the body, the arm gradually straightening as it leaves the water opposite the hip. When the hand is opposite the hip it should be brought quickly out of the water and sent forward for the next stroke. When the upper arm is opposite the shoulder in its pull through the water the legs are kicked wide apart and closed again at the moment when the hand leaves the water. The kick is completed and the legs straightened before the left hand is replaced ready for the next stroke. As the legs are opened the upper leg is kicked forward with the knee slightly bent, and the foot kept in its ordinary position. The lower leg is bent double until the heel approaches the thigh, which is brought backwards slightly. In the actual kick the upper leg is sent forward, and as it is straightened vigorously the under leg from the knee downward comes forward to meet it with a vicious kick; the swirl of the feet and closing of the legs drives the body forward. This is what has come to be known in Great Britain as the "Northern Kick," by reason of its first being introduced by Lancashire swimmers.

The *trudgen stroke*, more commonly known as the *trudgeon stroke*, and on the continent of Europe as *Spanish swimming*, was first made prominent in England in 1873 by a swimmer named J. Trudgen, who stated that he had acquired a knowledge of it while in South America. It was, however, known to Clias, a writer on swimming, who described it in 1825 as "The Thrust." Trudgen's speed was so great for his time that swimmers quickly copied his style, and it is from this stroke that the *crawl stroke* has been developed. When swimming Trudgen kept on the chest and lifted the upper part of his body at each stroke out of the water, and at each swing of the arms pulled himself forward, a considerable swirl of the water occurring as each movement was finished. The arms were brought forward sideways, each completing a circle on each side of the body, and the head kept completely above water. Those who copied Trudgen soon found it was less laborious and equally as fast to use a double over-arm stroke with the head and chest well down, and thus have the body supported by the water, using the ordinary over-arm leg kick. At first it was considered a stroke only useful for short distances and for water polo where speed is essential, but the idea was quickly dispelled, and several men, as well as women, have swum as far as fifteen miles with this stroke.

The *crawl stroke* is, like the *trudgen*, an adaptation from native swimmers. It was not generally known in Great Britain until 1902, when Mr Richard Cavill came from Australia to compete in the English championships, but it is said to be common with natives of the South Sea Islands, and from there introduced into Australia about the year 1900. From thence it came to Europe, and there Mr C. M. Daniels, the American amateur champion, made so excellent a study of it that he not only so greatly increased his own pace as to be able to win the English championship, and beat the world's record for a hundred yards, but also introduced various improvements upon it. This stroke is distinct from any other form of swimming: the legs from the knee upwards are kept in line with the body and almost closed; there is no opening of the legs or drawing up of the knees as for the breast, back and side strokes. The swimmer lies flat upon his breast on the surface, the lower part of the legs from the knee downward are alternately lifted above the surface up to the middle of the calf and then they are struck down upon the water with the instep with all force possible. This striking is done from an upward to a downward direction, one leg at a time. The arms are used somewhat similarly as in the trudgen stroke, they are bent at the elbows, dipped in just beyond the head and drawn smartly backwards till they come out of the water at the hips. The right arm is dipped in when the left foot strikes downward and vice versa. The result of this movement is that when one or the other of the limbs is pulling or propelling the body through the water at the same moment another limb is being recovered for the next stroke, most of the limbs are recovered through the air, fewer dead or retarding points are produced than in any other stroke, and less resistance is caused in the line of progress. In performing any other stroke most of the limbs are recovered through the water.

One of the most useful accomplishments for a swimmer is that of *floating*, but curiously enough many of them cannot acquire a knowledge of it. It is purely a matter of buoyancy, and requires constant practice before one can become perfect in it. In learning to float the beginner experiences great difficulty in overcoming the tendency of the legs to sink, and if after frequent trials they are still found to sink he should get some one to hold them up or else place them on the steps or behind the rail of the bath, and thus assisted learn to balance the body on the surface. Before doing so he should completely fill his lungs, spread his legs wide, and then lie backwards with the arms extended in a line with the body and beyond the head, with the palms upwards, care being taken to throw as much weight beyond the head as possible. Furthermore he must lie perfectly still and take care not to hollow the back or raise the abdomen above water. One may sink for an instant, but if the breath be held the lips will come above the surface, when easy breathing may be indulged in. Only the face, chest and toes should appear above the surface of the water. If the feet still have a tendency to sink after they have been gently released from the step or rail, more weight should be thrown beyond the head by turning it well back and lifting the hands out of the water, which will raise the feet. A knowledge of floating is of good service to those attempting to save life and is also essential to those desirous of making a study of the many tricks and scientific feats which are performed by swimmers.

The usual method of entering the water is by what is known as *diving*; some think that it should be termed "springing." The best method of learning to dive is to stand on the side of the bath or on the bank of the river, and then stoop down until the body is nearly double, stretch out the arms in front of the head, sink the head between them and gradually fall over into the water. The ability to enter the water head first will then soon be acquired. To begin, the legs should be placed together and the body kept erect, then a few short inspirations should be made and the lungs cleared and inflated, the arms should be swung from the front and a spring made from the diving base. As the feet leave the base they should be thrown upwards, the body straightened and the head placed between the arms, which should be kept at full stretch beyond the head, with the hands palm downwards and the thumbs touching so as to act as a cut-water. Immediately the body has entered the water, the hands should be turned upwards and the body will then come to the surface at once. In *high diving* a leap is made into mid-air, the body straightened almost to horizontal level, the arms and head then declined towards the water and the legs brought up. This action causes the body to shoot towards the water at a proper angle and the dive is thereby made clean and effective. A useful accomplishment is that known as *surface diving*, because it enables you to find and bring an object to the surface. The correct method of performing it is to first swim a few yards on the surface with the breast stroke, take a breath, then suddenly depress the head, look downwards, elevate the body at the hips, and at the same time make a powerful stroke with the legs and an upward stroke with the hands. The impetus thus obtained will suffice to take the swimmer to the bottom in 10 ft. of water. Once under the surface it is only necessary to keep the head depressed and swim by means of the breast stroke in order to find the object of search. When about to rise to the surface, the head should be turned backwards with the eyes upwards, and a vigorous stroke made with arms and legs. *Plunging* is not very generally practised, though there is a championship for it. A plunge is a standing dive made head first from a firm take off, free from spring. The body must be kept motionless face downwards, no progressive movement must be imparted other than the action of the dive. The plunge terminates when the plunger raises his face above the surface of the water. With the idea of preventing long tests without breathing, it was deemed in 1893 advisable by the swimming association to impose a time limit of one minute in all competitions. Yet even with this time limit, over 80 ft. has been plunged. In Sweden and Germany skilled forms of acrobatic and gymnastic diving have been more largely practised than in England, and as a consequence diving in those countries is in a much higher state of perfection than in England, though even in England great improvement has been made owing to a large influx of Swedish teachers.

Most of the principal races are decided in *baths*, but there has been a tendency of late years to revert to open water in the summer and also to encourage long-distance swimming. The first public baths in Great Britain were opened by the corporation of Liverpool in 1828 and the Baths and Washhouses Act was passed in 1846, the first of the London parishes to adopt the act being St Martin's in the Fields, who opened baths in Green Street, Leicester Square in 1846. Since then public baths have been erected all over Great Britain and Ireland, and bath swimming has become, by reason of the lack of reasonable open water accommodation, the principal means of the teaching of the young. But open water swimming, and more particularly swimming in the sea, is the best training and practice for those who really love the art, because they are able to swim under normal climatic conditions, instead of in tepid water. Many persons in England bathe in the open all the year round, notably in the Serpentine in London, on the sea-coast and in various inland waters.

When bathing in the open, care has to be taken to avoid weeds or undercurrents. In the event of accidentally getting hold of a bed of weeds, the swimmer should cease kicking and work with the arms, and the current will then take him through. If he tries to swim the weeds will entangle his legs and put him in an awkward plight. If he be carried away by a current in a river, he should select a spot on either bank and swim diagonally towards it, never minding where he has left his clothes. When in the sea, the conditions are not always the same, though the general rule of swimming diagonally for shore also applies. For sea bathing, however, it is far better, no matter how good a swimmer one may be, to have a boat in attendance. Before bathing in any strange place, the swimmer should make himself acquainted with the currents and the direction of the tide. When the tide is going out the course should be made along the coast, close in shore. In a rough sea the swimmer should not attempt to breast the waves, but as each wave rises he should swim through, thereby saving himself from buffeting, which if long continued would cause insensibility or else great waste of physical power. When using a boat for bathing the best way is to dive from the stern, to which some steps or a rope ladder should be fixed, in order to aid the swimmer when getting in again. Failing these being at hand, the best way is to lay hold of the stern with both hands and then, making a hard rising kick, raise the body till it rests on the edge of the hips. Then smartly slip the hands a little forward, turn to a sitting position and enter the boat.

Speed swimming *records* are so frequently altered, that students had best obtain the Amateur Swimming Association's Annual Handbook, in which are detailed the accepted records up to date. The improvement in speed has been most remarkable. In 1877 the mile amateur record was 29 m. $25\frac{1}{2}$ secs.; and that stood until 1892. The record in 1907 was 24 m. $42\frac{3}{5}$ secs. made by Mr D. Billington. The hundred yards record has been similarly reduced. In 1878 it was 1 m. $16\frac{3}{4}$ secs.; in 1888 it had been lowered by Mr J. Nuttall to 1 m. $6\frac{1}{4}$ secs.; and in 1907 Mr C. M. Daniels, of America, created a world's record of $55\frac{2}{5}$ secs. The records over intermediate distances have also been considerably lowered and many long-distance swimming records have from time to time been created. One of the most remarkable of these long-distance swims is the race which is known as the "Swim through London," from Richmond lock and weir to Blackfriars, which was instituted in 1907 and won by Mr J. A. Jarvis of Leicester, in 3 hours 24 minutes $6\frac{4}{5}$ secs. In this event 34 started, and 21 finished the distance, which goes to show that much attention is being devoted to long-distance trials; in this event Miss Lilian M. Smith finished fourteenth. Much interest has centred in attempts to swim across the English Channel; Captain Webb, D. Dalton and F. Cavill, all claim to have done it, but only the swim of Captain Webb has been accepted as genuine. The first recorded attempt was made on the 24th of August 1872 by J. B. Johnson, who started from Dover, but remained in the water only 65 minutes. It was on the 12th of August 1875 that Captain Matthew Webb made his first attempt. He started from Dover and remained in the water 6 hours 49 m., when the weather became too rough for him to continue. It is estimated that he was about $13\frac{1}{2}$ m.

across when he had to give up. On the 24th–25th of August 1875, he swam across the English Channel, diving from the Admiralty Pier, Dover, and touching Calais sands, France, after swimming for 21 hours 45 m. It is the greatest swim ever recorded, and at the time of the accomplishment created a great sensation in England. Since this great achievement, numerous unsuccessful attempts have been made, the best being those of Montague Holbein, Jabez Wolff and T. W. Burgess, and their efforts created an interest in long-distance swimming in all parts of the world, which has resulted in the accomplishment of trials and tests once thought impossible.

BIBLIOGRAPHY.—The literature of the subject of swimming is considerable; the most useful work of general reference is *Swimming*, by Ralph Thomas (London, 1904), with bibliography. Other chief works on the technic of swimming that may be mentioned are: Thevenot, *The Art of Swimming* (London, 1789); Steedman, *Manual of Swimming* (Melbourne, 1867); W. Wilson, *The Swimming Instructor* (London, 1883); A. Sinclair and W. Henry, *Swimming* (Badminton Library, London, 1893); C. M. Daniels, *How to Swim and Save Life* (Spalding's Library, London, 1907). (W. Hy.)

SWINBURNE, ALGERNON CHARLES (1837–1909), English poet and critic, was born in London on the 5th of April 1837. He was the son of Admiral Charles Henry Swinburne (of an old Northumbrian family) and of Lady Jane Henrietta, a daughter of George, 3rd earl of Ashburnham. It may almost be said to have been by accident that Swinburne owned London for his birthplace, since he was removed from it immediately, and always felt a cordial dislike for the surroundings and influences of life in the heart of a great city. His own childhood was spent in a very different environment. His grandfather, Sir John Edward Swinburne, bart., owned an estate in Northumberland, and his father, the admiral, bought a beautiful spot between Ventnor and Niton in the Isle of Wight, called East Dene, together with a strip of undercliff known as the Landslip. The two homes were in a sense amalgamated. Sir Edward used to spend half the year in the Isle of Wight, and the admiral's family shared his northern home for the other half; so that the poet's earliest recollections took the form of strangely contrasted emotions, inspired on the one hand by the bleak north, and on the other by the luxuriant and tepid south. Of the two, the influences of the island are, perhaps naturally, the stronger in his poetry; and many of his most beautiful pieces were actually written at the Orchard, an exquisite spot by Niton Bay, which belonged to relatives of the poet, and at which he was a constant visitor.

After some years of private tuition, Swinburne was sent to Eton, where he remained for five years, proceeding to Balliol College, Oxford, in 1857. He was three years at the University, but left without taking a degree. Clearly he must have cultivated while there his passionate and altogether unacademic love for the literature of Greece; but his undergraduate career was unattended by university successes, beyond the Taylorian prize for French and Italian, which he gained in 1858. He contributed to the "Undergraduate Papers," published during his first year, under the editorship of John Nichol, and he wrote a good deal of poetry from time to time, but his name was probably regarded without much favour by the college authorities. He took a second class in classical moderations in 1858, but his name does not occur in any of the "Final" honour schools. He left Oxford in 1860, and in the same year published those remarkable dramas, *The Queen Mother* and *Rosamond*, which, despite a certain rigidity of style, must be considered a wonderful performance for so young a poet, being fuller of dramatic energy than most of his later plays, and rich in really magnificent blank verse. The volume was scarcely noticed at the time, but it attracted the attention of one or two literary judges, and was by them regarded as a first appearance of uncommon promise.

It is a mistake to say, as most biographers do, that Swinburne, after leaving Oxford, spent some time in Italy with Walter Savage Landor. The facts are quite otherwise. The Swinburne family went for a few weeks to Italy, where the poet's mother, Lady Jane, had been educated, and among other places they visited Fiesole, where Landor was then living in the house that had been arranged for him by the kindness of the Brownings. Swinburne was a great admirer of Landor, and, knowing that he was likely to be in the same town with him, had provided himself with an introduction from his friend, Richard Monckton Milnes. Landor and Swinburne met and conversed, with great interest and mutual esteem; but the meetings were not for more than an hour at a time, nor did they exceed four or five in number. Swinburne never lived in Italy for any length of time. In 1865 appeared the lyrical tragedy of *Atalanta in Calydon*, followed in the next year by the famous *Poems and Ballads*, and with them the poet took the public gaze, and began to enjoy at once a vogue that may almost be likened to the vogue of Byron. His sudden and imperative attraction did not, it is true, extend, like Byron's, to the unliterary; but among lovers of poetry it was sweeping, permeating and sincere. The *Poems and Ballads* were vehemently attacked, but *Dolores* and *Faustine* were on everyone's lips: as a poet of the time has said, "We all went about chanting to one another these new, astonishing melodies." *Chastelard*, which appeared between *Atalanta* and *Poems and Ballads*, enjoyed perhaps less unstinted attention; but it is not too much to say that by the close of his thirtieth year, in spite of hostility and detraction, Swinburne had not only placed himself in the highest rank of contemporary poets, but had even established himself as leader of a choir of singers to whom he was at once master and prophet.

Meanwhile, his private life was disturbed by troublous influences. A favourite sister died at East Dene, and was buried in the little shady churchyard of Bonchurch. Her loss overwhelmed the poet's father with grief, and he could no longer tolerate the house that was so full of tender memories. So the family moved to Holmwood, in the Thames Valley, near Reading, and the poet, being now within sound of the London literary world, grew anxious to mix in the company of the small body of men who shared his sympathies and tastes. Rooms were found for him in North Crescent, off Oxford Street, and he was drawn into the vortex of London life. The Pre-Raphaelite movement was in full swing, and for the next few years he was involved in a rush of fresh emotions and rapidly changing loyalties. It is indeed necessary to any appreciation of Swinburne's genius that one should understand that his inspiration was almost invariably derivative. His first book is deliberately Shakespearian in design and expression; the *Atalanta*, of course, is equally deliberate in its pursuit of the Hellenic spirit. Then, with a wider swing of the pendulum, he recedes, in *Poems and Ballads*, to the example of Baudelaire and of the Pre-Raphaelites themselves; with the *Song of Italy* (1867) he is drawing towards the revolt of Mazzini; by the time *Songs before Sunrise* are completed (in 1871) he is altogether under the influence of Victor Hugo, while Rome has become to him "first name of the world's names." But, if Swinburne's inspiration was derivative, his manner was in no sense imitative; he brought to poetry a spirit entirely his own, and a method even more individual than his spirit. In summing up his work we shall seek to indicate wherein his originality and his service to poetry has lain; meanwhile, it is well to distinguish clearly between the influences which touched him and the original, personal fashion in which he assumed those influences, and made them his own. The spirit of Swinburne's muse was always a spirit of revolution. In *Poems and Ballads* the revolt is against moral conventions and restraints; in *Songs before Sunrise* the arena of the contest is no longer the sensual sphere, but the political and the ecclesiastical. The detestation of kings and priests, which marked so much of the work of his maturity, is now in full swing, and Swinburne's language is sometimes tinged with extravagance and an almost virulent animosity. With *Bothwell* (1874) he returned to drama and the story of Mary Stuart. The play has fine scenes and is burning with poetry, but its length not only precludes patient enjoyment, but transcends all possibilities of harmonious unity. *Erechtheus* (1876) was a return to the Greek inspiration of *Atalanta*; and then in the second series of *Poems and Ballads* (1878) the French influence is seen to be at work, and Victor Hugo begins to hold alone the place possessed, at different times, by Baudelaire and Mazzini. At this time Swinburne's energy was at fever height; in 1879 he published his eloquent *Study of Shakespeare*, and in 1880 no fewer than three volumes, *The Modern Heptalogia*, a brilliant anonymous essay in parody, *Songs of the Springtides*, and *Studies in Song*. It was shortly after this date that Swinburne's friendship for Theodore Watts-Dunton (then Theodore Watts) grew into one of almost more than brotherly intimacy. After 1880 Swinburne's life remained without disturbing event, devoted entirely to the pursuit of literature in peace and leisure. The conclusion of the Elizabethan trilogy, *Mary Stuart*, was published in 1881, and in the following year *Tristram of Lyonesse*, a wonderfully individual contribution to the modern treatment of the Arthurian legend, in which the heroic couplet is made to assume opulent, romantic cadences of which it had hitherto seemed incapable. Among the publications of the next few years must be mentioned *A Century of Roundels*, 1883; *A Midsummer Holiday*, 1884; and *Miscellanies*, 1886. The current of his poetry, indeed, continued unchecked; and though it would be vain to pretend that he added greatly either to the range of his subjects or to the fecundity of his versification, it is at least true that his melody was unbroken, and his magnificent torrent of words inexhaustible. His *Marino Faliero* (1885) and *Locrine* (1887) have passages of power and intensity unsurpassed in any of his earlier work, and the rich metrical effects of *Astrophel* (1894) and *The Tale of Balin* (1896) are inferior in music and range to none but his own masterpieces. In 1899 appeared his *Rosamund, Queen of the Lombards*; in 1908 his *Duke of Gardia*; and in 1904 was begun the publication of a collected edition of his Poems and Dramas in eleven volumes.

Besides this wealth of poetry, Swinburne was active as a critic, and several volumes of fine impassioned prose testify to the variety and fluctuation of his literary allegiances. His *Note on Charlotte Brontë* (1877) must be read by every student of its subject; the *Study of Shakespeare* (1880)—followed in 1909 by *The Age of Shakespeare*—is full of vigorous and arresting thought, and many of his scattered essays are rich in suggestion and appreciation. His studies of Elizabethan literature are, indeed, full of "the noble tribute of praise," and no contemporary critic did so much to revive an interest in that wonderful period of dramatic recrudescence, the side-issues of which have been generally somewhat obscured by the pervading and dominating genius of Shakespeare. Where his enthusiasm was heart-whole, Swinburne's appreciation was stimulating and infectious, but the very qualities which give his poetry its unique charm and character were antipathetic to his success as a critic. He had very little capacity for cool and reasoned judgment, and his criticism is often a tangled thicket of prejudices and predilections. He was, of course, a master of the phrase; and it never happened that he touched a subject without illuminating it with some lightning-flash of genius, some vivid penetrating suggestion that outflames its shadowy and confused environment. But no one of his studies is satisfactory as a whole; the faculty for sustained exercise of the judgment was denied him, and even his best appreciations are disfigured by error in taste and proportion. On the other hand, when he is aroused to literary indignation the avalanche of his invective sweeps before it judgment, taste and dignity. His dislikes have all the superlative violence of his affections, and while both alike present points of great interest to the analyst, revealing as they do a rich, varied and fearless individuality, the criticism which his hatreds evoke is seldom a safe guide. His prose work also includes an early novel of some interest, *Love's Cross-currents*, disinterred from a defunct weekly, the *Tatler*, and revised for publication in 1905.

Whatever may be said in criticism of Swinburne's prose, there is at least no question of the quality of his poetry, or of its important position in the evolution of English literary form. To treat first of its technique, it may safely be said to have revolutionized the whole system of metrical expression. It found English poetry bound in the bondage of the iambic; it left it revelling in the freedom of the choriambus, the dactyl and the anapaest. Entirely new effects; a richness of orchestration resembling the harmony of a band of many instruments; the thunder of the waves, and the lisp of leaves in the wind; these, and a score other astonishing poetic developments were allied in his poetry to a mastery of language and an overwhelming impulse towards beauty of form and exquisiteness of imagination. In *Tristram of Lyonesse* the heroic couplet underwent a complete metamorphosis. No longer wedded to antithesis and a sharp caesura, it grew into a rich melodious measure, capable of an infinite variety of notes and harmonies, palpitating, intense. The service which Swinburne rendered to the English language as a vehicle for lyrical effect is simply incalculable. He revolutionized the entire scheme of English prosody. Nor was his singular vogue due only to this extraordinary metrical ingenuity. The effect of his artistic personality was in itself intoxicating, even delirious. He was the poet of youth insurgent against all the restraints of conventionality and custom. The young lover of poetry, when first he encounters Swinburne's influence, is almost bound to be swept away by it; the wild, extravagant licence, the apparent sincerity, the vigour and the verve, cry directly to the aspirations of youth like a clarion in the wilderness. But, while this is inevitable, it is also true that the critical lover of poetry outgrows an unquestioning allegiance to the Swinburnian mood more quickly than any other of the diverse emotions aroused by the study of the great poets. It is not that what has been called his "pan-anthropism"—his universal worship of the holy spirit of man—is in itself an unsound philosophy; there have been many creeds founded on such a basis which have impregnably withstood the attacks of criticism. But the unsoundness of Swinburne's philosophy lies in the fact that it celebrates the spirit of man engaged in a defiant rebellion that leads nowhere; and that as a "criticism of life" it has neither finality nor a sufficiently high seriousness of purpose. Walt Whitman preaches very much the same gospel of the "body electric" and the glory of human nature; but Whitman's attitude is far saner, far more satisfying than Swinburne's, for it is concerned with the human spirit realizing itself in accordance with the unchangeable laws of nature; while Swinburne's enthusiasm is, more often than not, directed to a spiritual revolution which sets the laws of nature at defiance. It is impossible to acquit his poetry entirely of the charge of an animalism which wars against the higher issues of the spirit—an animalism sometimes of love, sometimes of hatred, but, in both extremes, out of centre and harmony.

Yet, when everything has been said that can be said against the unaesthetic violences of the poet's excesses, his service to contemporary poetry outweighed all disadvantages. No one did more to free English literature from the shackles of formalism; no one, among his contemporaries, pursued the poetic calling with so sincere and resplendent an allegiance to the claims of absolute and unadulterated poetry. Some English poets have turned preachers; others have been seduced by the attractions of philosophy; but Swinburne always remained an artist absorbed in a lyrical ecstasy, a singer and not a seer. When the history of Victorian poetry comes to be written, it will be found that his personality was, in its due perspective, among the most potent of his time; and as an artistic influence it will be pronounced both inspiring and beneficent. The topics that he touched were often ephemeral; the causes that he celebrated will, many of them, wither and desiccate; but the magnificent freedom and lyrical resource which he introduced into the language will enlarge its borders and extend its sway so long as English poetry survives.

On the 10th of April 1909, after a short attack of influenza followed by pneumonia, the great poet died at the house on Putney Hill, "The Pines," where with Mr Watts-Dunton he had lived for many years. He was buried at Bonchurch, Isle of Wight. (E. G.)

SWINDON, a market town and municipal borough in the Cricklade parliamentary division of Wiltshire, England, $77\frac{1}{4}$ m. W. of London by the Great Western railway. Pop. (1891), 33,001; (1901), 45,006. It has two parts, New and Old. The new town grew up around the vast locomotive and wagon works of the Great Western railway, and is an important junction on that system with a separate station on the Midland and South-Western Junction railway. It arose rapidly on a strip of waste land, and churches and chapels were built for the workmen, whose numbers soon exceeded 10,000. Each man contributes to a medical fund which maintains the fever, accident and general hospitals, providing also laundries and baths. There are a mechanics' institute, containing a large library, theatre, reading-rooms and lecture-hall. The company owns a park with football and cricket grounds. An aisle of St Saviour's Church, dedicated in 1905, was built by the priest and congregation with their own hands. The picturesque old town stands on a hill overlooking the Gloucestershire borders, the White Horse Vale and Lambourn Down in Berkshire, and the great chalk uplands of Marlborough; while the camps of Blunsdon, Ringsbury, Barbury and Badbury are all visible. Here the chief buildings are the church, town-hall, market-hall and corn exchange. Old Swindon received the right of holding a fair from Charles I. Coate Reservoir, less than 2 m. south-east, is a broad lake which supplies a branch of the Berks and Wilts Canal. Its shores are beautifully wooded, and it abounds with fish. Swindon is governed by a mayor, 12 aldermen and 36 councillors. Area, 4265 acres.

SWINE, a name properly applicable to the domesticated pig (*Sus scrofa*), but also including its wild relatives. As stated in the article ARTIODACTYLA, these animals typify the family Suidae, which, with the Hippopotamidae, constitute the section Suina, a group of equal rank with the Pecora. The Suidae are divisible into the true Old World swine (Suinae) and the American peccaries (Dicotylinae). Of the former the leading characteristics are as follows: an elongated mobile snout, with an expanded, truncated, nearly naked, flat, oval terminal surface in which the nostrils are placed. Feet narrow, with four completely developed toes on each. Hoofs of the two middle toes with their contiguous surfaces flattened. The outer toes not reaching to the ground in the ordinary walking position. Teeth variable in number, owing to the suppression in some forms of an upper incisor and one or more premolars.

In the typical genus *Sus*, as exemplified by domesticated pigs (see PIG) and the wild boar (see BOAR), the dentition is $i.\frac{3}{3}$, $c.\frac{1}{1}$, $p.\frac{4}{4}$, $m.\frac{3}{3}$; total 44; the upper incisors diminishing rapidly in size from the first to the third, and the lower incisors long, narrow, closely approximated, and almost horizontal in position, their tips inclining towards the middle line, the second slightly larger than the first, the third much smaller. The tusks or canines are strongly developed, with

FIG. 1.—Dentition of Boar (*Sus scrofa*).

persistent roots and a partial enamel covering, those of the upper jaw not having the usual downward direction, but curving outwards, upwards and finally inwards, while those of the lower jaw are directed upwards and outwards with a gentle backward curve, their hinder edges working and wearing against the front edges of the upper pair. The tusks appear externally to the mouth, the form of the upper lip being modified to allow of their protrusion, but are much less developed in females than in males. The teeth of the molar series gradually increase in size and complexity from first to last, and are arranged in contiguous series, except that the first lower premolar is separated by an interval from the second. First and second upper premolars with compressed crowns and two roots; and the third and fourth with an inner lobe of the crown, and an additional pair of roots. The first and second molars have quadrate crowns, with four principal obtuse conical cusps, around which numerous accessory cusps are clustered. The crown of the third molar is nearly as long as those of the first and second together, having, in addition to the four principal lobes, a large posterior heel, composed of clustered conical cusps, and supported by additional roots. The lower molars resemble generally those of the upper jaw, but are narrower. Milk dentition: $i.\frac{3}{3}$, $c.\frac{1}{1}$, $m.\frac{3}{3}$; total 28—the first permanent premolar having no predecessor. The third incisor in both upper and lower jaws is large, developed before the others, with much the size, form and direction of the canine. Vertebrae: C. 7, D. 13–14, L. 6, S. 4, Ca. 20–24. The hairy covering of the body varies under different conditions of climate, but when best developed, as in the European wild boar, consists of long stiff bristles, abundant on the back and sides, and of a close softer curling under-coat.

All the typical swine are further characterized by the fact that the young are longitudinally striped with bands of dark brown and some paler tint; this striped coat disappearing in the course of a few months. On the other hand, this peculiar marking is rarely seen in domestic pigs in any part of the world, although it has been occasionally observed. It is stated by Darwin that the pigs which have run wild in Jamaica and New Granada have resumed this aboriginal character, and produce longitudinally striped young; these being the descendants of domestic animals introduced from Europe since the Spanish conquest, as before that time there were no true pigs in the New World. Another character by which the European domesticated pig differs from any of the wild species is the concave outline of the frontal region of the skull.

In the wild boar (*Sus scrofa*) the upper or hinder surface of the lower tusk, which has no enamel, inclines obliquely outwards and is broader than the outer surface. The distributional area

FIG. 2.—Wild Boar and Young (*Sus scrofa*).

of this species includes northern Africa, Europe and central and northern Asia as far as Amurland. Whether the Nubian *S. senarensis* is really distinct, seems doubtful. To the same group belongs the Indian *S. cristatus*, distinguished by the more pronounced development of the crest of long hairs on the nape of the neck, and closely related to the next species. The third species is the banded pig *S. vittatus*, of Sumatra, characterized by having a broad reddish or whitish band running from the middle of the snout along the upper lip to disappear on the side of the neck; the skull being short and high, with the facial portion of the lachrymal bone small. Races of this type are also met with in Java, Cochin-China and Formosa; the pig from the latter island having been named *S. täivanus*. Near akin is the Japanese *S. leucomystax* and the small Andamanese *S. andamanensis*. Whether the New Guinea *S. papuensis* and *S. niger* are really indigenous members of this group or modified descendants of European tame pigs is doubtful; although the general character of the Papuan fauna supports the idea that they are introduced.

A second group is typified by the warty pig, *S. verrucosus*, of Java, in which the hinder or upper unenamelled surface of the lower tusk is narrower than the outer, concave, and set nearly in the long axis of the skull. The skull itself is elongated, with comparatively simple and primitive molars, the latter being relatively short. There are also three small warts on each side of the face, the largest of which is just below the eye and carries long bristles. The small *S. celebensis* of Celebes and *S. philippinensis* are probably only varieties of this species. The bearded pig *S. barbatus* (=*longirostris*) of Borneo is a very distinct member of this group, distinguished by the great elongation of the skull, and the presence of a tuft of long hair near the muzzle. In Sumatra it is represented by the subspecies *S. b. öi*, and in south-west Borneo by *S. b. gargantua*.

Some doubt exists whether the pygmy hog of the Nepal Terai, which is not much larger than a hare, is best regarded as a member of the typical genus, under the name of *Sus salvanius* or as representing a genus by itself, with the title *Porcula salvania*.

Similar doubts have also been entertained with regard to the African bush-pigs or river-hogs, but from geographical considerations alone these are but regarded as representing a separate genus, *Potamochoerus*, although they are nearly allied to the *verrucosus* group of *Sus*. They are specially distinguished by the great development of the anterior half of the zygomatic arch of the skull, and by the presence in the boars of a horny protuberance of the skin in front of each eye, which overlies a tuberosity on the nasal bone; the molars are also small and simple, and the anterior premolars are generally shed at an early stage of life. The group is represented in Madagascar, as well as in Africa south of the Sahara. (See RIVER-HOG.)

The recently discovered *Hylochoerus* of the equatorial forest-districts of Africa comes nearest to the under-mentioned wart-hogs, but the skull is of a much less specialized type, while the upper tusks are much smaller although they have the same general curvature and direction, and the cheek-teeth lack the peculiar characteristics of those of *Phacochoerus*, although they present a certain approximation thereto. On the other hand, resemblance to that genus is shown by the reduction of the upper incisors to a single pair. The skin is clothed with a thick coat of coarse black hair of a bristly nature, but there are a few whitish hairs on the face and in the groin.

In the African wart-hogs (*Phacochoerus*), which take their name from the large warty lobes projecting from each side of the face, the teeth are remarkably modified. The milk-dentition, and even the early condition of the permanent dentition, is formed on the same general type as that of *Sus*, except that certain teeth are absent, the formula being $i\frac{1}{3}$, $c\frac{1}{1}$, $p\frac{3}{2}$, $m\frac{3}{3}$, total 34; but as age advances all the teeth have a tendency to disappear, except the canines and the posterior molars, but these, which in some cases are the only teeth left in the jaws, attain an extraordinary development. The upper canines especially are of great size, and curve outwards, forwards and upwards. Their enamel covering is confined to the apex, and soon wears away. The lower canines are much more slender, but follow the same curve; except on the posterior surface, their crowns are covered with enamel; both pairs of canines are large in the two sexes. The third or last molar tooth of both jaws is of great size, and presents a structure at first sight unlike that of any other mammal, being composed of numerous (22–25) parallel cylinders or columns, each with pulp-cavity, dentine and enamel-covering, and packed together with cement. Examination will, however, show that a modification similar to that which has transformed the comparatively simple molar tooth of the mastodon into the extremely complex grinder of the Indian elephant has served to change the tooth of the common pig into that of *Phacochoerus*. The tubercles which cluster over the surface of the crown of the common pig are elongated and drawn out into the columns of the wart-hog, as the low transverse ridges of the mastodon's tooth become the leaf-like plates of the elephant's molar. (See WART-HOG.)

The last existing representative of the *Suidae* is the babirusa of Celebes, alone representing the genus of the same name, and readily distinguished by the extraordinary size and form of the tusks of the old males. (For the characteristics of this animal see BABIRUSA.)

Extinct Swine.—Species of *Sus* are met with in Pliocene strata of Europe and Asia, the Lower Pliocene *S. erymanthius* of Greece and *S. giganteus* and *S. titan* of India being enormous animals; the last with comparatively simple molars. The European *S. palaeochoerus* and the Indian *S. hysudricus* are smaller forms; the first exhibiting signs of relationship with *Potamochoerus*. In India also occurs *Hippohyus* distinguished by the extremely complicated structure of its molars. In the European Miocene we have *Hyotherium* and *Palaeochoerus*, and in the Upper Oligocene *Propalaeochoerus*, which have square molars without any tendency to a selenodont structure in their cusps. Curiously enough a selenodont type is, however, apparent in those of the imperfectly known Egyptian *Geniohyus* of the Upper Eocene, the earliest species which can be included in the family. Even in this the forward direction of the lower incisors is noticeable. *Choeropotamus* is a European Oligocene genus with bunodont molars which show a conspicuous basal cingulum in the lower dentition; the first premolar is absent. In the European Miocene *Listriodon*, which also occurs in the Indian Tertiaries, the molars have a pair of transverse ridges, like those of the proboscidean *Dinotherium* (*q.v.*); but the genus is believed to be related to the Oligocene *Doliochoerus* and *Choerotherium*, in which these teeth show a more normal type of structure.

For the genus *Elotherium*, of the Lower Miocene and Upper Oligocene of both hemispheres, which is often placed next the Suidae, see ARTIODACTYLA. The American Dicotylinae are noticed under PECCARY. (R. L.*)

SWINEMÜNDE, a port and seaside resort of Germany, in the Prussian province of Pomerania, situated at the east extremity of the island of Usedom, and on the left bank of the river Swine which connects the Stettiner Haff with the Baltic. Pop. (1905), 13,272. It serves as the outer port of Stettin (*q.v.*), 42 m. distant by water, with which, as with Heringsdorf, it has direct railway communication. Its broad unpaved streets and one-storey houses built in the Dutch style give it an almost rustic appearance. although its industries, beyond some fishing, are entirely connected with its shipping. The entrance to the harbour, the best on the Prussian Baltic coast, is protected by two long breakwaters, and is strongly fortified. The grand lighthouse, 216 ft. high, rises beside the new docks on the island of Wollin, on the other side of the narrow Swine. In 1897 the river continuation of the Kaiserfahrt was opened to navigation, and, further, the waterway between the Haff and the Baltic was deepened to 24 ft. in 1900–1901 and in other ways improved. The connexion between Swinemünde and Stettin is kept open in winter by ice breakers. Formerly ships of heavy burden bound for Stettin discharged or lightened their cargo at Swinemünde, but since the recent deepening of the river Oder they can proceed direct to the larger port.

The Swine, the central and shortest passage between the Stettiner Haff and the Baltic Sea, was formerly flanked by the fishing villages of West and East Swine. Towards the beginning of last century it was made navigable for large ships, and Swinemünde, which was founded on the site of West Swine in 1748, was fortified and raised to the dignity of a town by Frederick the Great in 1765.

See Wittenberg, *Swinemünde, Ahlbeck und Heringsdorf* (Linz, 1893).

SWING, DAVID (1830–1894), American clergyman, was born of Alsatian stock in Cincinnati, Ohio, on the 23rd of August 1830. He spent most of his boyhood on a farm and earned his schooling; graduated at Miami University in 1852; studied theology at Lane Seminary; and was principal of the preparatory school at Miami in 1853–1866. He became pastor in 1866 of the Westminster Presbyterian Church (after 1868 the Fourth Church) in Chicago, which was destroyed in the fire of 1871; he then preached in McVicker's theatre until 1874, when a new building was completed. In April 1874 he was tried before the presbytery of Chicago on charges of heresy preferred by Dr Francis Landey Patton, who argued that Professor Swing preached that men were saved by works, that he held a "modal" Trinity, that he did not believe in plenary inspiration, that he unduly countenanced Unitarianism, &c. The presbytery acquitted Dr Swing, who resigned from the presbytery when he learned that the case was to be appealed to the synod. As an action was taken against the church, of which he had remained pastor, he resigned the pastorate, again leased McVicker's theatre (and after 1880 leased Central Music Hall, which was built for the purpose), and in 1875 founded the Central Church, to which many of his former parishioners followed him, and in which he built up a large Sunday school, and established a kindergarten, industrial schools, and other important charities. He died in Chicago on the 3rd of October 1894. He was an excellent preacher, but no theologian. He published *Sermons* (1874), including most of his "heretical" utterances, *Truths for To-day* (2 vols., 1874–1876), *Motives of Life* (1879), and *Club Essays* (1881).

See Joseph F. Newton, *David Swing, Poet-Preacher* (Chicago, 1909).

SWINTON, an urban district in the Rotherham parliamentary division of the West Riding of Yorkshire, England, 10½ m. N.E. of Sheffield, on the Midland, North Eastern and Great Central railways. Pop. (1891), 9705; (1901), 12,217. It is situated at the junction of the Dearne and Dove navigation with the river Don navigation. In the churchyard of St Margaret's church (rebuilt in 1817) two beautiful Norman arches of the old church are preserved. There are collieries, quarries and brickfields in the neighbourhood. There are also flint and glass-bottle works, ironworks (for stoves, grates, fenders and kitchen ranges), and earthenware manufactures. The town was formerly renowned for its Rockingham ware. A free warren was granted to Swinton by Henry II.

SWINTON AND PENDLEBURY, an urban district in the Eccles parliamentary division of Lancashire, England, 5 m. N.W. of Manchester, with stations on the Lancashire & Yorkshire railway. Pop. (1901), 27,005. The church of St Peter, a fine building of stone with a lofty western tower, was erected from the designs of Sir Gilbert Scott in 1869. The Swinton industrial schools, opened in February 1846, are a fine range of buildings of brick with stone facings, surrounded with grounds extending to 20 acres. The manufacture of cotton, and coal-mining are the chief industries. Anciently a large part of Swinton was possessed by the Knights Hospitallers of St John of Jerusalem.

SWITCHBACK, a form of pleasure railway, built over alternate descents and ascents, the train or car first gathering momentum by running down an incline, and surmounting by means of this a lesser ascent. Switchbacks were originally merely an imitation, using cars upon wheels, of the sledge-coasting courses of Russia, and were indeed named by the French *montagnes russes*. They were introduced in Paris in 1816, but soon disappeared in consequence of several serious accidents. About 1880 they again became popular both in Europe and America. A variation of the switchback, though lacking its essential principle of climbing by means of momentum, is the water-chute, an imitation of the Canadian toboggan-slide, in which cars built in the shape of boats glide down steep inclines into artificial lakes at their bases. This is popularly called "shooting the chutes." A further variation is "looping the loop," in which a heavy car on wheels, or a bicycle, starting at a considerable altitude, descends an incline so steep that sufficient momentum is accumulated to carry it completely round a track in the form of a perpendicular loop, in the course of which journey the occupants or rider, while crossing the top of the loop, are actually head downwards. Later it was made even more dangerous by taking out part of the top of the loop, so that the car or bicycle actually passes through the air across the gap.

SWITCH PLANTS, a botanical term for plants, such as broom, with leaves very small or absent, and slender green shoots.

SWITHUN (or SWITHIN), **ST** (d. 862), bishop of Winchester and patron saint of Winchester Cathedral from the 10th to the 16th century. He is scarcely mentioned in any document of his own time. His death is entered in the *Anglo-Saxon Chronicle* under the year 861; and his signature is appended to several charters in Kemble's *Codex diplomaticus*. Of these charters three belong to 833, 838, 860–862. In the first the saint signs as "Swithunus presbyter regis Egberti," in the second as "Swithunus diaconus," and in the third as "Swithunus episcopus." Hence if the second charter be genuine the first must be spurious, and is so marked in Kemble. More than a hundred years later, when Dunstan and Ethelwold of Winchester were inaugurating their church reform, St Swithun was adopted as patron of the restored church at Winchester, formerly dedicated to St Peter and St Paul. His body was transferred from its almost forgotten grave to Ethelwold's new basilica on the 15th of July 971, and according to contemporary writers, numerous miracles preceded and followed the translation.

The revival of St Swithun's fame gave rise to a mass of legendary literature. The so-called *Vitae Swithuni* of Lantfred and Wulstan, written about A.D. 1000, hardly contain any germ of biographical fact; and all that has in later years passed for authentic detail of St Swithun's life is extracted from a biography ascribed to Gotzelin, a monk who came over to England with Hermann, bishop of Salisbury from 1058 to 1078. From this writer, who has perhaps preserved some fragments of genuine tradition, we learn that St Swithun was born in the reign of Egbert, and was ordained priest by Helmstan, bishop of Winchester (838–*c.* 852). His fame reached the king's ears, who appointed him tutor of his son Adulphus (Æthelwulf) and numbered him amongst his chief friends. Under Æthelwulf he was appointed bishop of Winchester, to which see he was consecrated by Archbishop Ceolnoth. In his new office he was remarkable for his piety and his zeal in building new churches or restoring old ones. At his request Æthelwulf gave the tenth of his royal lands to the Church. His humility was such that he made his diocesan journeys on foot; and when he gave a banquet he invited the poor and not the rich. He built near the eastern gate of his cathedral city a bridge whose stone arches were so strongly constructed that in Gotzelin's time they seemed a work "non leviter ruiturus." He died on the 2nd of July 862, and gave orders that he was not to be buried within the church, but outside in "a vile and unworthy place."

William of Malmesbury adds that, as Bishop Alhstan of Sherborne was Æthelwulf's minister for temporal, so St Swithun was for spiritual matters. The same chronicler uses a remarkable phrase in recording the bishop's prayer that his burial might be "ubi et pedibus praetereuntium et stillicidiis ex alto rorantibus esset obnoxius." This expression has been taken as indicating that the well-known weather myth contained in the doggrel lines—

St Swithin's day if thou dost rain
For forty days it will remain;
St Swithin's day if thou be fair
For forty days 'twill rain na mair—

had already, in the 12th century, crystallized round the name of St Swithun; but it is doubtful if the passage lends itself by any straining to this interpretation. James Raine suggested that the legend was derived from the tremendous downpour of rain that occurred, according to the Durham chroniclers, on St Swithun's day, 1315 (*Hist. Dunelm.* pp. xiii. 96–97). Another theory, more plausible, but historically worthless, traces it to a heavy shower by which, on the day of his translation, the saint marked his displeasure towards those who were removing his remains. This story, however, cannot be traced further back than some two or three centuries at the outside, and is at variance with the 10th-century writers, who are all agreed that the translation took place in accordance with the saint's desire as expressed by vision. More probable is John Earle's suggestion that in the legend as now current we have the survival of some pagan or possibly prehistoric day of augury, which has successfully sheltered itself under the protection of an ecclesiastical saint. This view is supported by the fact adduced in *Notes and Queries* (1st series, xii. 137) that in France St Médard (June 8) and St Gervase and St Protais (June 19) are credited with an influence on the weather almost identical with that attributed to St Swithun in England. Similarly we have in Flanders St Godelieve (July 6) and in Germany the Seven Sleepers' Day (June 27). Of other stories connected with St Swithun the two most famous are those of the Winchester egg-woman and Queen Emma's ordeal. The former is to be found in Gotzelin's life (*c.* 1100), the latter in T. Rudborne's *Historia major* (15th century)—a work which is also responsible for the not improbable legend that Swithun accompanied Alfred on his visit to Rome in 856.

The so-called lives of St Swithun written by Wulstan, Lantfred, and perhaps others towards the end of the 10th century may be found in Bollandus's *Acta sanctorum* (July), i. 321–327; Mabillon's *Acta SS. O. B.* vi. 70, &c., vii. 628, &c.; and J. Earle's *Life and Times of St Swithun*, 59, &c. See also William of Malmesbury, *Gest. reg.* i. 150, and *De gest. pont.* 160, 167, 179; Florence of Worcester, i. 168; T. Rudborne ap. Wharton's *Anglia sacra*, i. 287; T. D. Hardy's *Cat. of MSS.* i. 513–517; J. Brand's *Popular Antiquities*; R. Chambers's *Book of Days*; Ethelwulf's *Tithe Charters*, nearly all of which refer to St Swithun in the body of the text, may be studied in Haddon and Stubbs's *Councils*, iii. 636–645; a comparison of the charter on page 642 with Gotzelin's life (ap. Earle, 69) and William of Malmesbury (*Gest. reg.* 150; *De gest. pont.* 160) seems to show that these charters, even if forgeries, date back at least to the 11th century, as well as the story of his being Ethelwulf's "altor et ductor."

SWITZERLAND, a republican country of central Europe, comprising the Swiss Confederation, and bounded N. by the

German Empire, E. by Austria (except where the principality of Liechtenstein intervenes), S. by Italy, and W. by France.

Physical Description.—Switzerland extends between the parallels 45° 49′ 2″ and 47° 48′ 32″ lat. (Greenwich) and the meridians 5° 57′ 26″ and 10° 29′ 40″ long. (Greenwich). It forms an irregular quadrilateral, of which the greatest length from east to west is 226½ m., and the greatest breadth from north to south is nearly 137 m. (136·8). It has, however, no proper physical unity, as it consists of a number of small districts, differing from each other widely in language, religion, ethnology, customs, &c., but bound together in a political alliance, made originally for common defence against a common foe. It is therefore an artificial land, just as its inhabitants form an artificial nation, though nowadays it is becoming more homogeneous in both respects. Its political boundaries thus do not coincide with those of nature. The entire canton of Ticino is south of the Alps, as are the valleys of Simplon (Valais), Mesocco, Bregaglia, Poschiavo and Münster (all in the Grisons); the whole canton of Schaffhausen and part of that of Basel are north of the Rhine, while a large part of the Grisons lies to the east of the Rhine basin, and Porrentruy is far down on the western slope of the Jura. But it is to be noted that all these exceptional cases were outside the limits of the Swiss Confederation up to 1798. Putting them aside, the physical geography of Switzerland may thus be described:—

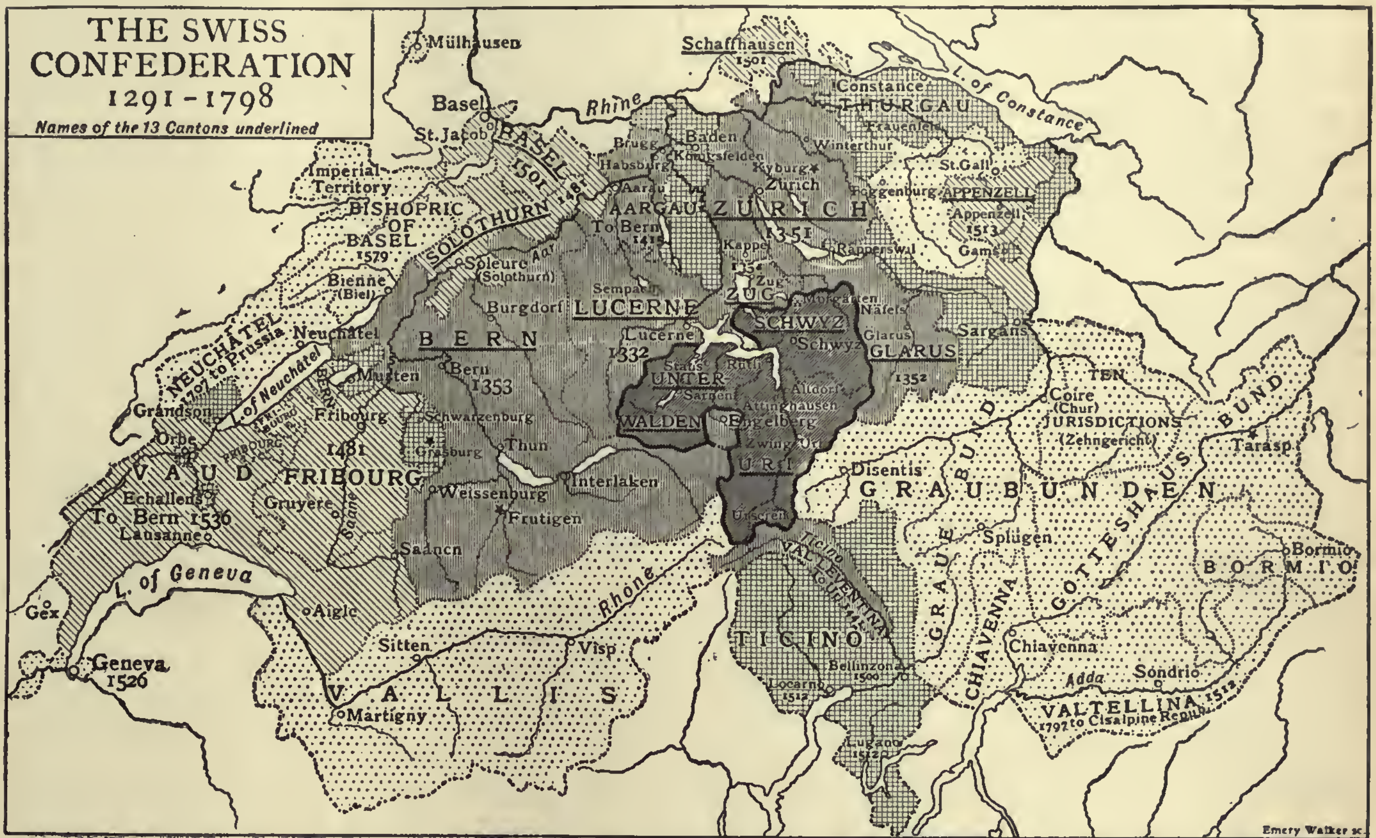
1. On the south runs the main chain of the Alps (*q.v.*), which is joined, at the Mont Dolent (12,543 ft.) in the chain of Mont Blanc, by the lower ranges that rise south of the Lake of Geneva, and which continues partly Swiss till close to the Stelvio Pass on the east.

2. To the north of this main chain there is another great range of mountains (wholly Swiss) only slightly inferior in extent and height, which starts from the hills known as the Jorat range above Lausanne, and culminates in the great snowy summits of the Bernese Oberland and of the Tödi group, before trending to the north near Coire, and, after rising once more in the Säntis group, dies away on the southern shore of the Lake of Constance.

3. The Swiss portion of the main chain of the Alps and this great northern outlier run parallel to each other from the Mont Dolent to near Coire, while for a short distance they actually unite near the Pizzo Rotondo (west of the St Gotthard Pass), parting again near the Oberalp Pass (east of the St Gotthard). Between these two great snowclad ranges flow two of the mightiest European rivers, the Rhone towards the west and the Rhine towards the east, their headwaters being only separated by the tangled mountain mass between the Pizzo Rotondo and the Oberalp Pass, which sends the Reuss towards the north and the Ticino towards the south.

4. To the north of this great northern outlier rises the Jura range (*q.v.*), really a huge spur of the Alps (with which it is connected by the Jorat range), while between the northern outlier and the Jura extends what may be called the plains or "plateau" of Switzerland, consisting all but wholly of the undulating valley of the Aar (below Thun) with its numerous affluents. To that river valley we must add the valley of the Thur (a direct affluent of the Rhine), that lies between the Aar basin and the Rhine basin (the Lake of Constance).

We may thus roughly describe Switzerland (as it exists at the present time) as consisting of three great river valleys (Rhone, Rhine and Aar) with the smaller one of the Thur, which all lie to the north of the main chain of the Alps and include the region between the Alps and the Jura. If we examine matters more carefully we note that the Rhone and Rhine valleys are shut off from that of the Aar (and, of course, of the Thur) by the great northern outlier of the Alps, which consists of the Bernese Oberland and Tödi Alps. Two wide and undulating valleys (Aar and Thur) and two deeply cut trenches (Rhone and Rhine) thus lie on the northern slope of the Alps, to the north and south respectively of the great northern outlier of the Alps. The main chain of the Alps rises in Swiss territory to the height of 15,217 ft. in the loftiest summit or Dufourspitze (wholly Swiss) of Monte Rosa, though the Dom (14,942 ft.), in the Mischabel range, between Zermatt and Saas, is the highest mountain mass which is entirely Swiss. The great northern outlier attains a height of 14,026 ft. in the Finsteraarhorn (Bernese Oberland), while the lowest level (581 ft.) within the Confederation is on the Lago Maggiore. The highest



The 3 original Cantons (Die Urkantone) 1291-1332 — The 8 ancient Cantons 1353-1481 (5 added between 1332 and 1353) — The 13 Cantons 1513-1798 (5 added between 1481 and 1513)

Allied and Protected Districts — Subject Districts — Dates of Confederation, Alliance or Conquest, are shown thus:- 1512

Subject States incorporated with Cantons are indicated by the word To with the date of incorporation:- To Bern 1536 permanently inhabited village in Switzerland is Juf (6998 ft.), at the head of the Avers valley (a tributary of the Hinter Rhine, Grisons), while the lowest is Ascona (666 ft.), on the Lago Maggiore and just south-west of Locarno.

According to the most recent calculations, the total area of Switzerland is 15,951 sq. m. (some 2500 sq. m. less than that of Servia). Of this 11,927·5 sq. m. (or 74·8%) are reckoned as "productive," forests occupying 3,390·9 sq. m. and vineyards 108·7 sq. m., the remainder, or 8427·7 sq. m., consisting of arable and pasture land. Of the "unproductive" area of 4023·5 sq. m (or 25·2%) much consists of lakes and rivers, while glaciers cover 709·7 sq. m. Approximately the Alps occupy one-sixtieth of this area, the Jura about one-tenth, and the "plateau" the rest. Of the entire area the great cantons of the Grisons, Bern and the Valais take up 7411·8 sq. m., or nearly one-half, while if to them be added Vaud, Ticino and St Gall the extent of these six (out of twenty-two) cantons is 10,527·6 sq. m., or almost two-thirds of the area of the Confederation. Not included in the total area of Switzerland are three small "enclaves" (4 sq. m. in all), Büsingen and Verenahof (both in Schaffhausen) belonging to Baden, while Campione (opposite Lugano) is Italian. Switzerland borders on many countries—France west and south-west, Italy south, Austria east (Tirol and Vorarlberg), and Germany north (Bavaria, Württemberg, Baden and Alsace). Switzerland sends its waters to four great river basins (which drain to three different seas) in the following proportions: Rhine basin, 11,159 sq. m.; Rhone basin, 2768 sq. m.; Po basin, 1361 sq. m.; and Inn basin, 663 sq. m.

The thirteen cantons which till 1798 formed the Confederation are all comprised in the Rhine basin, the ten oldest (*i.e.* all before 1500) being within that of the Aar, and it was only after 1798 that certain Romonsch-, French- and Italian-speaking "allies" and subject lands—with their river basins—were tacked on to them.

Most of the great Swiss rivers, being in their origin mere mountain torrents, tend to overflow their banks, and hence much is required and has been done to prevent this by embanking them, and regaining arable land from them. So the Rhine (between Ragatz and the Lake of Constance), the Rhone, the Aar, the Reuss; and in particular we may mention the great work on the Linth (1807–1816) carried out by Hans Konrad Escher, who earned by his success the surname of "Von der Linth," and on the Zihl near the lakes of Neuchâtel and Bienne, while the diversion of the Kander from its junction with the Aar at Thierachern to a channel by which it flows into the Lake of Thun was effected as early as 1714.

There are very many *lakes*, large and small, in Switzerland. The two most extensive, those of Geneva and of Constance, balance each other, as it were, at the south-west and north-east corners of the land. But neither of these is wholly Swiss, this distinction being claimed by the next in size, that of Neuchâtel (92·4 sq. m.), the Lago Maggiore (partly Swiss only) coming next in the list, and being followed by the wholly Swiss lakes of Lucerne and of Zürich. Then come Lugano, Thun, Bienne, Zug, Brienz, Morat, the Walensee, and Sempach ($5\frac{1}{2}$ sq. m.). These fourteen only are over 4 sq. m. in extent. Eleven of them are in the Rhine basin (also in that of the Aar), two (Maggiore and Lugano) in that of the Po, and one (Geneva) in that of the Rhone. There are no large lakes in the Swiss portion of the Inn basin, the most extensive being that of Sils ($1\frac{1}{2}$ sq. m.). Of the smaller lakes those best known to travellers are the Daubensee (near the summit of the Gemmi), the Oeschinensee (at the foot of the Blümlis Alp range) and the Märjelensee, formed by the damming up of the waters of the Great Aletsch glacier by a huge lateral moraine. Alpine tarns are innumerable.

Of the countless *waterfalls* in Switzerland those of the Rhine (near Schaffhausen) have volume but not height, while the reverse is the case in varying degrees with those of the Aar at the Handegg, of the Reichenbach, of Pissevache, and particularly of the Staubbach, a mere thread of water falling clear of a cliff of great height.

There are said to be 1077 *glaciers* in Switzerland, but it is really impossible to estimate the number accurately, as practically all are now in retreat, and it is not easy to say whether an isolated fragment of ice is or is not entitled to rank as an independent glacier. From them flow all the more important Swiss rivers and streams. Yet their distribution is very unequal, for eleven cantons (just one-half of the Confederation) have none. The Valais heads the list with 375 sq. m., then come the Grisons (138·6), Bern (111·3), Uri (44·3), Glarus (13·9) and Ticino (13·1). The five others (Unterwalden, Vaud, St Gall, Schwyz and Appenzell) boast of 13·3 all together. The three longest glaciers in the Alps are all in the great northern outlier (not in the main chain)—the Great Aletsch ($16\frac{1}{2}$ m.), the Fiescher and the Unteraar (each 10 m.). In the main chain the Gorner ($9\frac{1}{4}$ m.) is the longest. Of glaciers covering an area of over 6 sq. m. no fewer than 17 are in Switzerland, as against two each in the French portion of the chain of Mont Blanc and in the Eastern Alps.

Forests cover 21·2% (3390·99 sq. m.) of the total area of Switzerland. Of the six most extensive cantons five are also at the head in the matter of forests: Bern (591 sq. m.), the Grisons (503), Vaud (320), the Valais (297·4) and Ticino (267·2). St Gall (157) ranks in this respect after Zürich (180·8) and Aargau (172), while the only other cantons with over 100 sq. m. are Lucerne (120·4), Fribourg (119) and Soleure (111·3), the lowest place being taken by Geneva (9·9). By far the greater part (67%) of the forest area belongs to the communes or private corporations, while 28·5% is in the hands of private individuals (much of this having become private property in the time of Napoleon I.), but only 4·5% is in the hands of the state, in consequence of the suppression of many monasteries. The communes own 94·3% of the forest area in the Valais, private individuals 78·8% in Lucerne, and the state 16% in Schaffhausen. Schaffhausen and the Jura cantons are the most wooded in proportion to their area, while at the other end of the scale are the towns of Geneva and Basel, and the barren canton of Uri. The great floods of 1834, 1852 and 1868 drew attention to the negligent administration of the forests, considered specially as a protection against damage due to the forces of nature. A forestry department was created in the polytechnic school in Zürich when it was opened in 1855. The Federal Constitution of 1874 (art. 24) handed over to the Confederation the oversight of the forests "in the high mountains," this being interpreted to mean the Alps with their spurs, but not to include the Jura, and a law of 1876 was enacted to carry out this task. In 1897 the limitation mentioned above was struck out, so that the Confederation now has oversight of *all* forests within its territory, a law of 1902 regulating in detail the whole subject. Since 1876 much has been done, either directly by the Confederation or indirectly by subsidizing the efforts of the cantons, to reafforest districts where the trees had been recklessly cut down, and to ensure the proper administration of forests generally.

Geology.—The greater part of Switzerland is occupied by the belts of folded rock which constitute the Alps and the Jura (*q.v.*). The central plain, however, is covered by nearly undisturbed deposits of Oligocene and Miocene age, concealed in many places by glacial, alluvial and other accumulations of later date. Both the Oligocene and the Miocene beds are, for the most part, of fresh-water or brackish-water origin, but the middle of the Miocene series is formed of marine deposits. During this period an arm of the Mediterranean spread up the valley of the Rhone. It reached its maximum extension during the middle portion of the Miocene period, when it appears to have stretched continuously along the outer border of the Alps from the present Golfe du Lion into Austria; but at an earlier and a later date it was represented in Switzerland only by a series of brackish-water lagoons or fresh-water lakes.

Climate.—In Switzerland, where the height above sea-level ranges from 581 ft. (Lago Maggiore) to 15,217 ft. (Monte Rosa), we naturally find very many climates, from the regions of olives, vines, oaks and beeches, pines and firs, to those of the high mountain pastures, rhododendrons, and of eternal snow. It has been reckoned that, while in Italian Switzerland winter lasts only three months, at Glarus (1578 ft.) it lasts four, in the Engadine (5945 to 3406 ft.) six, on the St Gotthard (6936 ft.) eight, on the Great St Bernard (8111 ft.) nine, and on the St Théodule Pass (10,899 ft.) practically always. The highest mean annual temperature (53° F.) in Switzerland is naturally that at Lugano (909 ft.), while at Bevers (5610 ft., Upper Engadine) the lowest mean temperature in winter is −14° F., but the highest in summer is 77° F., an immense difference. At Montreux the annual mean is 50°, at Sion, Basel, Geneva and Coire about 49°, at Zürich 48°, at Bern and Lucerne 47·5°, at St Gall 45°, at Davos 37·5°, at Sils-Maria 34·5°, and on the Great St Bernard 29°. Of course many factors, such as the shape of the ground, the sheltered position of the place, the degree of exposure to sunshine, counterbalance the mere height at which the town is situated.

The snow-clad Alps of course have the heaviest rain- or snow-fall in Switzerland, this being estimated at 89·7 in. per annum. The greatest actually recorded rainfall (87·3 in.) was on the San Bernardino Pass (6769 ft.), while the lowest (21·7 in.) was at Sierre (1767 ft., Valais). At Lugano the average annual rainfall is 65·4 in., on the Great St Bernard 48·7 in., at Lucerne 45·6 in., at Montreux 42·6 in., at Sils-Maria 37 in., at Bern and Davos 36·6 in., and at Basel, Coire and Geneva about 32·7 in. It has been shown by careful observations that the rain- or snow-fall is greatest as we approach the Alps, whether from the north or the south, the flanks of the great ranges and the valleys opening out towards the plains receiving much more rain than the high Alpine valleys enclosed on all sides by lofty ridges. Thunderstorms generally vary in frequency with the amount of rainfall, being most common near the great ranges, and often very local. The floods caused by excessive rainfall are sometimes very destructive, as in 1834, 1852 and 1868, while the same cause leads to landslips, of which the most remarkable have been those of the Rossberg above Goldau (1806), at Evionnaz (1835) and at Elm (1881). The Föhn (*q.v.*) is the most remarkable local wind.

For all these reasons Switzerland has many varieties of climate; and, while, owing to the distribution of the rainfall, the Ticino and

Aar valleys are very fertile, the two great trenches between the main chain and its north outlier, though warm, are less productive, as the water comes from the rivers and not from the skies.

People.—The first estimate of the population of Switzerland with any pretence to accuracy was that of 1817, which put the number at 1,687,900. The first regular census took place in 1836 to 1838, but was therefore not synchronous, while it was also not very systematic—the number was put at 2,190,258. That of 1850 was better organized, while in 1860 the census was declared decennial, a slight alteration being made as to that of 1888 for practical reasons. The following was the number of the population usually resident (the number of those actually present was also taken, but all detailed subdivisions refer only to the residents): in 1850, 2,392,740; in 1860, 2,510,494; in 1870, 2,655,001; in 1880, 2,831,787; in 1888, 2,917,754; and in 1900, 3,315,443. The density per square mile was as follows: 150 in 1850; 157 in 1860; 159 in 1870; 177 in 1880; 182 in 1888; and 207 in 1900. The increase in the whole of the country from 1850 to 1900 was 39%. Thirteen cantons showed an increase lower than this average, the lowest of all being Aargau, Glarus and Lucerne; while in Bern the increase of the towns did not counterbalance the diminution in the country districts. The nine cantons which increased above the average rate did so either owing to special circumstances (*e.g.* the construction of the Simplon railway in the Valais), or because their industries were very flourishing (*e.g.* St Gall), or because they contain great towns (*e.g.* Zürich). The highest rates of increase were shown by Geneva (107% increase) and the half canton of Urban Basel (278% increase). As to the actual distribution of the population, the Alpine regions are the sparsest generally (with the exception of the Outer Rhodes of Appenzell), the Jura region has a much higher ratio, while the densest region of all is the Swiss plateau. The strong attraction of the towns is shown by the facts that between 1850 and 1900 the population of the nineteen largest nearly tripled, while, in 1900, of the 187 "political districts" in Switzerland 41 showed a decrease, and they were all exclusively rural.

The shifting of the population within the country is also proved when we note that in 1900 but 38·5% of the Swiss citizens inhabited their commune of birth, though the proportion was 64% in 1850. If we consider the different cantons, we find that in 1900 31·5% (in 1850 but 26·4%) lived in another commune within their canton of birth, while 18·4% (as against 6·6% in 1850) dwelt in a canton other than their canton of birth. To sum up, in 1850, out of the 25 cantons and half cantons, no fewer than 21 had a majority of citizens living in their commune of birth, while in 1900 the number was but 11, and those all rural cantons. Of the 3164 *communes* (or civil parishes) in Switzerland, only 21 in 1900 had a population exceeding 10,000, while 20 had under 50 inhabitants. If we look at the height of the communes above the sea-level, we find that there were but 3 (with a population of 463 souls) above 1900 metres (2953 ft.), while 68 (with a total population of 188,394) were below 300 metres (984 ft.). The number of inhabited houses rose from 347,327 in 1860 (the number was not taken in 1850) to 434,084 in 1900, while that of separate households mounted from 485,087 in 1850 (528,105 in 1860) to 728,920 in 1900.

The *non-Swiss element* of the population increased from 3% in 1850 to 11·6% in 1900, and its number from 71,570 in 1850 to 383,424 in 1900. The Germans are the most numerous, next in order come Italians, French and Austrians. In 1900 there were 3535 British subjects resident in Switzerland, and 1559 citizens of the United States. Of course most of the non-Swiss are found in the towns, or in rural districts where any great railway line is being constructed.

The *emigration* of Swiss beyond seas was but 1691 in 1877, though it rose in 1883 to 13,502 (the maximum as yet attained). Then the number fell pretty steadily till 1899 (2493), then rose again, and in 1906 was 5296. About 89% go to the United States, and about 6% to the Argentine Republic (mainly from the French-speaking cantons). Bern, Zürich, Ticino, the town of Basel and St Gall are the chief cantons which furnish emigrants.

In the matter of *religion*, the Protestants formed 59·3% in 1850 and 57·8% in 1900, and the Roman Catholics (including the "Christian" or "Old" Catholics, who arose in 1874) 40·6% and 41·6% respectively, while the Jews increased from 1% in 1850 to 4% in 1900—the remainder (other religions or none) being 2% in 1860 (not reckoned separately in 1850) and in 1900. Ten and a half cantons have a majority of Protestants, while in the rest the "Catholics" have the upper hand. The same proportion prevailed in 1850, save that then Geneva had a Protestant majority, whereas in 1870 already the balance had shifted, owing to the number of immigrants from France and Italy.

As to *languages* habitually spoken, Switzerland presents a very variegated picture. By the Federal Constitutions of 1848 (art. 109) and 1874 (art. 116), German, French and Italian are recognized as "national languages," so that debates in the Federal parliament may be carried on in any of the three, while Federal laws, decrees, &c., appear also in the three. The old historical dialects of Romonsch and Ladin (nearly confined to the canton of the Grisons, *q.v.*) enjoy no political recognition by the Confederation, are largely maintained by artificial means in the shape of societies founded for their preservation, and are not even in the majority (which is German) in the Grisons. Of the other 21 cantons, all have a German-speaking majority save 6—French prevails in Fribourg, Vaud, the Valais, Neuchâtel and Geneva, and Italian in Ticino. Since the census of 1880, when detailed inquiries as to language were made for the first time, there has been a certain amount of shifting, as is shown by the following figures. German was spoken by 71·3 of the population in 1880, by 71·4 in 1888 and by 69·8 in 1900; the figures for French are respectively 21·4, 21·8 and 22, and for Italian 5·7, 5·3 and 6·7, while Romonsch fell from 1·4 to 1·3 and 1·2%. "Other languages" were 2, 2 and 3%. Thus in 1900 there were nearly 70% of German-speaking persons, as against nearly 30% who spoke one or other of the Romance tongues. The most interesting cases are the cantons of Fribourg (*q.v.*) and the Valais (*q.v.*), in which French is advancing at the expense of German.

Chief Political Divisions and Towns.—When considering Switzerland it must never be forgotten that, strictly speaking, the only political "divisions" are the 187 "districts" into which the cantons are divided (Bern has 30, Vaud 19 and St Gall 15, no others having over 15). These are administrative districts, created for political purposes. The cantons themselves are not "divisions" but sovereign states, which have formed an alliance for certain purposes, while they are built up out of the 3164 "communes," which are really the political units. Of the 22 cantons,[1] 3 are subdivided—Unterwalden (from before 1291) into Obwalden and Nidwalden, and Appenzell (since 1597) into the Outer Rhodes and the Inner Rhodes, while Basel (since 1833) forms urban Basel (the city) and rural Basel (the country districts). The Swiss political capital is Bern (by virtue of a Federal law of 1848), while the Federal Supreme Tribunal is (since its foundation in 1874) at Lausanne, and the Federal Polytechnic School (since it was opened in 1855) at Zürich.

In 1900 there were 19 towns in Switzerland which had a population exceeding 10,000 souls, all having increased very much within the 50 previous years. The following are the six largest, the figures for 1850 being enclosed within brackets: Zürich, 150,703 (35,483); Basel, 109,161 (27,844); Geneva, 104,796 (42,127), Bern, 64,227 (27,558); Lausanne, 46,732 (17,108), and La Chaux de Fonds, 35,968 (13,659). Thus Geneva was first in 1850, but only third in 1900. Thirteen of these nineteen towns are cantonal capitals, though La Chaux de Fonds, Winterthur, Bienne, Tablat (practically a suburb of St Gall), Le Locle and Vevey are not, while no fewer than twelve cantonal capitals (Sion, Bellinzona, Aarau, Altdorf, Schwyz, Frauenfeld, Glarus, Liestal, Sarnen, Stans, Appenzell and Zug) are below this limit. It is reckoned that while the 19 Swiss towns having over 10,000 inhabitants had in 1850 a population of 255,722, that number had swollen in 1900 to 742,205.

Communications.—The carriage roads of Switzerland were much improved and increased in number after a strong Federal government was set up in 1848, for it largely subsidized cantonal undertakings. In the course of the 19th century many splendid roads were carried over the Alpine passes, whether within or leading from Swiss territory; in the latter case with financial aid from Italy (or till 1859 Austria, as the mistress of the Milanese). The earliest in date was that over the Simplon (1800–1807), while others were opened respectively over the Furka (7992 ft.) in 1867, to the top of the Great St Bernard (8111 ft.) in 1893, over the Grimsel (7100 ft.) in 1895, and over the Klausen Pass (6404 ft.) in 1900. The highest carriage road entirely within Switzerland is that over the Umbrail Pass (8242 ft.), opened in 1901, and leading from the Swiss upper Münster valley to close to the Stelvio.

The first Swiss lake over which a steamer plied regularly was that of Geneva (1823), followed by Constance (1824), Lago Maggiore (1826), Neuchâtel (1827), Thun (1835), Lucerne (1835) and

[1] The cantons are—Aargau, Appenzell, Basel, Bern, Fribourg, Geneva, Glarus, Grisons, Lucerne, Neuchâtel, St Gall, Schaffhausen, Schwyz, Soleure, Thurgau, Ticino, Unterwalden, Uri, Valais, Vaud, Zug, Zürich (see separate articles).

Brienz (1839). The first railway opened within Switzerland was that (14 m. long) from Zürich to Baden in Aargau (1847), though the Swiss bit of that from Basel to Strassburg had been opened in 1844. From 1852 to 1872 the cantons granted concessions for the building of railways to private companies, but from 1872 onwards the conditions were other and the lines were constructed under Federal supervision. In the 'fifties and 'sixties many lines were built, but not always according to sound financial principles, so that in 1878 the great "National Railway" became bankrupt. Hence the idea of the state purchase of the chief lines made considerable progress, so that in 1898 such a scheme was accepted by the Swiss people. Accordingly in 1901 most of the great lines became Federal railways, and the Jura-Simplon in 1903, while the Gotthard line became Federal in 1909. This state ownership only applies to the main lines, not to the secondary lines or to the mountain cog-wheel railways (of which the first was that from Vitznau up the Rigi, 1871) now so widespread throughout the country. The highest point as yet attained in Switzerland by a mountain railway is the Eismeer station (10,371 ft.) of the line towards the Jungfrau. Many tunnels have been pierced through the Swiss Alps, such as the St Gotthard (1882), the Albula (1903) and the Simplon (1906). The highest line carried over a Swiss pass is that over the Little Scheidegg (6772 ft.).

Industries.—a. Of the Land. If we look at the annual turnover there is no doubt that the principal Swiss industry is that of the entertainment of foreign visitors, for its gross receipts are larger than those of any other branch. It appears from the official statistics that in 1905 its gross receipts amounted to rather over £7,500,000 (as against about £4,500,000 in 1894, and rather over £2,000,000 in 1880), the net profit being nearly £1,500,000 (as against £656,000 and nearly £300,000 respectively), while in 1905 the capital invested in this industry was rather over £31,000,000 (as against £20,750,000 and £12,750,000 respectively). In 1905 there were in Switzerland 1924 hotels (of which 402 were in Bern and 358 in the Grisons) specially built for the accommodation of foreign visitors, containing 124,068 beds, and employing 33,480 servants (the numbers for 1894 and 1880 are 1693 and 1002, 88,634 and 58,137, and 23,997 and 16,022 respectively). Part of this increase is due to the fashion of visiting Switzerland in winter for skating, tobogganing, skiing, &c.

Of the actual "productive" soil about two-thirds is devoted to arable or pasturage purposes, but the latter branch is by far the more important, occupying about 83% of this two-thirds, for Switzerland is much more a pastoral than an agricultural country. In 1906 the number of cattle was officially put at 1,497,904 (as against 1,340,375 in 1901 and 993,291 in 1866). In summer they are supported on the numerous mountain pastures or "alps" (see ALPS, 2), which number 4778, and are of an estimated capital value of rather over £3,000,000, while in winter they are fed on the hay mown on the lower meadows or purchased from outside. Two main breeds of cattle are found in Switzerland, the dun race (best represented by the cattle of Schwyz) and the dappled race (of which the Simme valley beasts are of the red and white kind, and those of the Gruyère of the black and white variety). The best Swiss cheeses are those of the Emmenthal and of the Gruyère, while the two principal condensed milk factories (Nestlé at Vevey and that at Cham) are now united. It should be noted that the proportion of the land devoted to pastoral pursuits increases, like the rainfall, from the west and north-west to the east and north-east, so that it is highest (nearly 90%) in Appenzell and St Gall. As regards other domestic animals, the number of swine increased from 304,428 in 1866 to 566,974 in 1896 (the maximum recorded), but in 1906 fell to 548,355. The number of goats has remained pretty steady (359,913 in 1906 to 375,482 in 1866, the maximum, 416,323, being attained in 1886), but that of sheep has decreased from 447,001 in 1866 to 209,443 in 1906.

It is stated that but 14% of the "productive" area of Switzerland is corn-growing, this proportion being however doubled in Vaud. Hence for its food supply the country is largely dependent on its imports, the home supply sufficing for 153 days only. Tobacco is grown to a certain extent, especially near Payerne in the Broye valley (Vaud) and in Ticino, while more recently beetroot has been cultivated for the purpose of manufacturing sugar. Fruit and vegetables are made into jams and concentrated foods at Lenzburg and Kemptthal, while *kirschwasser* (cherry brandy) is made in Zug. Forests cover about 28½% of the "productive" area of Switzerland. They are now well cared for, and produce considerable profits.

Vineyards in Switzerland now cover 108·7 sq. m., though the area is steadily decreasing owing to the competition of foreign cheap wines. The only cantons which have over 10% of their area thus planted are Vaud (25%), Ticino (20%), Zürich (17%) and the Valais (10·7%). Among the best Swiss wines are those of La Côte, Lavaux and Yvorne (all in Vaud), and Muscat, Fendant and Vin du Glacier (all in the Valais). Those grown near Neuchâtel, at the northern end of the lake of Zürich, near Baden (Aargau), and along the Swiss bank of the Rhine, are locally much esteemed.

Among the raw mineral products of Switzerland the most important is asphalt, which is worked by an English company in the Val de Travers (Neuchâtel). Various metals (even including gold and silver) exist in Switzerland, but are hardly worked at all, save iron (Delémont), copper (Val d'Anniviers) and argentiferous lead (Lötschenthal). True coal is wholly absent, but lignites occur here and there, and are sometimes worked (*e.g.* at Käpfnach, Zürich). Anthracite is found in the Valais, while peat is worked in many parts. Salt was first found at Bex (Vaud) in 1544, and the mines are still worked. But far more important are the saline deposits along the Rhine, from near Basel to Coblenz (at the junction of the Rhine and the Aar), which were discovered at Schweizerhall in the year 1836, at Kaiseraugst in 1844, at Rheinfelden in 1845 and at Ryburg in 1848. Marble, sandstone and granite are worked in various spots for building purposes. Marl, clay and limestone are also found, and are much used for the manufacture of various kinds of cement. There are said to be 620 mineral springs in Switzerland, the best known being those at Baden in Aargau and at Schinznach (both sulphur), Schuls-Tarasp and St Moritz, Stachelberg, Ragatz and Pfäfers, Leukerbad and Weissenburg. The most important slate quarries are those in the canton of Glarus. The relative importance of the Swiss industries concerned with the land is best shown by the census taken in 1900 as to the occupations of the inhabitants. No fewer than 1,035,010 (about one-third of the total population) were engaged in pastoral or agricultural pursuits, as against 19,334 employed in market gardening, 18,233 in various matters touching the forests, 12,785 in the vineyards and 12,323 in extracting minerals (of these 8004 were employed in stone or marble quarries).

b. Manufactures.—The same census also shows the relative importance of the chief branches of manufacture in Switzerland—textile industries 270,114 (of which 88,457 were in the silk branch and 63,853 in that of cotton), watchmaking 115,617, embroidery 89,558, besides 74,148 engaged in the manufacture of machinery. Eastern Switzerland is the industrial portion of the land, though watchmaking and some minor industries are carried on in the Jura. The textile industries are by far the most important in Switzerland, Zürich and its neighbourhood being the main centre both for silk (this branch was revived by the Protestant exiles from Italy in the 16th century) and cotton, while St Gall, Appenzell and Thurgau are mainly devoted to embroidery, and Basel to the silk ribbon and floss silk departments. The watchmaking industry has been established in Geneva since the end of the 16th century, and spread in the early 18th century to the Neuchâtel portion of the Jura (centre La Chaux de Fonds and Le Locle). Musical boxes are chiefly made at Ste Croix in the Vaud section of the Jura, while Geneva is famous for its jewelry and goldsmiths' work. The growth of the manufacture of machines is much more recent, having originally been a mere adjunct of the textile industry, and developed in order to secure its independence of imports from England. Its centres are in and around Zürich, Winterthur, St Gall and Basel. Among other products and industries are chocolate (Suchard, Cailler, Sprüngli, Tobler, Peter, Maestrani, &c.), shoemaking (Schönenwerd), straw plaiting (Aargau and Gruyère), wood carving (Brienz in the Bernese Oberland since 1825), concentrated soups and meats (Maggi's factory is at Kemptthal near Winterthur), aniline dyes (Basel), aluminium (Neuhausen in Schaffhausen).

Commerce.—Switzerland is naturally adapted for free trade for it depends on the outside world for much of its food-stuffs and the raw materials of its manufactures. After the adoption of the Federal Constitution of 1848, customs duties within the land were abolished, while moderate duties only were levied on imports, the sum increasing as the articles came more or less within the category of luxuries, but being lowest on necessaries of life. Down to 1870 Switzerland was all but entirely on the side of free trade. Since that time it has been becoming more and more protectionist. This change was due in part to the increased tariffs levied in Germany and France, and in part to the strong pressure exercised by certain branches of the Swiss manufacturing industries, while treaties of commerce have been made with divers countries. Hence in 1903 the Swiss people adopted the principle of a greatly increased scale of duties, the detailed tariff of the actual sums levied on the various articles coming into force on the 1st of January 1906. These higher duties were meant to serve as a weapon for obtaining better terms in future commercial treaties, but were finally increased still more at the instigation of certain of the great manufacturers, so that Switzerland became decidedly a protectionist country. In 1901 the receipts from the customs duties were about £1,858,000, while in 1905 they were £2,541,000, and in 1907 rather more (£2,894,000).

Excluding goods in transit, the total value of imports rose from about £36,500,000 in 1895 to about £55,000,000 in 1905, while between the same dates the exports rose from about £26,500,000 to £38,750,000—in other words, the unfavourable balance of trade had increased from £10,000,000 in 1895 to £16,250,000 in 1905.

The increase during the same period in the case of the four great articles of export from Switzerland was as follows: silk from nearly £8,500,000 to rather over £10,000,000, embroideries from nearly £3,000,000 to £5,000,000, watches from £3,500,000 to £5,250,000, and machinery from rather under £1,000,000 to £2,250,000.

Government.—The Swiss Confederation must be carefully distinguished from the 22 cantons of which it is composed, and which are sovereign states, save in so far as they have given up their rights to the Federal government. These cantons themselves are built up of many political communes, or Gemeinden, or civil parishes, which are the real political units of the country (and not merely local subdivisions); for any one desiring to become naturalized a Swiss must first become (by purchase or grant) a member of a commune, and then, if his burghership of the commune is confirmed by the cantonal authorities, he obtains also, simultaneously, both cantonal and Federal citizenship.

a. Now in Switzerland there are 3164 *political communes* (*municipalités* or *Einwohnergemeinden*). These are composed of all male Swiss citizens over twenty years of age, of good character and resident in the commune for at least three months. The meeting of these persons is called the *assemblée générale* or *Gemeindeversammlung*, while the executive council chosen by it is the *conseil municipal* or *Gemeinderat*, the chief person in the commune (elected by the larger meeting) being termed the *syndic* or *maire*, the *Gemeindepräsident* or the *Gemeindeammann.* This kind of commune includes all Swiss residents (hence the German name) within its territorial limits, and has practically all powers of management of local affairs, including the carrying out of cantonal and Federal laws or decrees, save and except matters relating to the pastures and forests held in common. This class of commune dates only from the time of the Helvetic republic (1798–1802), and its duties were largely increased after the liberal movement of 1830; the care of the highways, the police, the schools, the administration of the poor law being successively handed over to it, so that it became a political body. As regards Swiss citizens belonging to cantons other than that in which they reside, the Federal Constitution of 1848 (art. 41) gave them rights of voting there in cantonal and Federal matters, but not in those relating exclusively to the commune itself. The Federal Constitution of 1874 (art. 43) gives to such persons as those named above (*établis* or *Niedergelassenen*—that is, permanent settlers) all voting rights, Federal, cantonal and communal (save as below), the two last named after a stay of three months. Temporary residents being Swiss citizens (*e.g.* labourers, servants, students, officials not being communal officials) are called *résidents* or *Aufenthalter*, and are in most cantons considered to be as such incapable of voting in communal matters until after a residence of three months, though some cantons require a longer sojourn. Foreign residents are included under this class of *Aufenthalter*.

The *burgher communes* (*communes bourgeoises* or *Bürgergemeinden*), now principally of historical interest, having for the most part gradually merged with the other class of communes, were originally simply the communities that dealt with the management of the "lands subject to common user" or *Allmend* (mainly summer pastures and forests), but gradually obtained, by purchase or otherwise, the manorial rights, the burghers then being themselves the lords of the manor (as at Brixham in Devonshire). But when after the Reformation, owing to the suppression of the monasteries, the care of the poor was imposed by the Federal Diet, in 1551, on the several communes, these naturally aided only their own members, a course which gave rise to a "communal burghership," a system designed to prevent persons from gaining a "settlement" in any commune to which they did not properly belong. Thus all non-burgher residents, permanent or temporary, were excluded from any share in the enjoyment of the lands subject to common user, or in their management, and remained complete outsiders, though paying local rates. With the increased facilities of communication and the rise of a shifting industrial population such restrictions became invidious and unfair, particularly after the introduction, under the Helvetic republic, of a Federal citizenship, superior to cantonal citizenship, and after the communes became more and more burdened with public duties, so that the amount of the rates equalled, if it did not exceed, the sums produced by the "common lands." To avoid some of these inconveniences "political communes" were set up, consisting practically of all Swiss permanent residents. But the relation between these and the old *Bürgergemeinden* (the burghers of which only have rights of user over the common lands) was very delicate, and has been settled (if settled at all) in various fashions. In some cases the older communes simply merged with the newer, the ownership of the common lands thus passing from one to the other class. In other cases the *Bürgergemeinden* still exist as distinct from the "political communes," but solely for purposes (enjoyment, management, &c.) relating to the common lands, and thus form a sort of privileged community inside the larger and now more generally important community. In some cases the common lands have been divided in varying proportions between the two classes of communes, the *Bürgergemeinden* thus continuing to exist solely as regards that part of the common lands which they have retained. In other cases the common lands, whether before or after 1798, have passed into the possession of a small number of the burghers, who form a close corporation, the revenues of which are enjoyed by the members as such, and not as citizens—in short are subject to no public obligations or burdens save rates and taxes.

b. The twenty-two cantons (three are subdivided—Unterwalden, Appenzell and Basel—into two halves) are divided into "administrative districts" (187 in number), which are ruled by prefects, in the French fashion, appointed by the cantonal authorities. These are the true local divisions in the country. Each canton has its own legislature, executive and judiciary. The older cantons have in some cases (Uri, Unterwalden, Appenzell and Glarus) preserved their ancient democratic assemblies (or *Landesgemeinden*), in which each burgher appears in person, and which usually meet once a year, on the last Sunday in April or the first Sunday in May, always (weather permitting) in the open air. These annual assemblies elect annually a sort of standing committee, and also the chief magistrate or *Landammann*, as well as the judiciary. In the other eighteen cantons the legislature (*Gross Rat* or *grand conseil*) is composed of representatives chosen by the cantonal voters in proportion, varying in each canton, to the population. They are thus local parliaments rather than mere county councils. The executive (*Regierungsrat* or *conseil d'état*) is elected everywhere (save Fribourg, the Valais and Vaud) by a popular vote, this plan having gradually superseded election by the cantonal legislature. All the cantons (save Fribourg) have the referendum and initiative, by which the electors can exercise control over their elected representatives. The cantonal judiciary is chosen by the people.

c. In 1848 the *Federal government* was reorganized according to the plan adopted in the United States, at any rate so far as regards the *legislature* (*Bundesversammlung* or *assemblée fédérale*). This is composed of two houses: (1) the *Ständerat* or *conseil des états*, to which each canton, great or small, sends two representatives (generally chosen for varying terms by the people, but, in 1907, still by the cantonal legislature in Bern, Fribourg, Neuchâtel, St Gall, the Valais and Vaud), this house being like the American Senate; (2) the *Nationalrat* or *conseil national*, composed of representatives (at present 167 in number) elected within the cantons in the proportion of 1 to every 20,000 (or fraction over 10,000) of the population, and holding office for three years, before the expiration of which it cannot be dissolved. The two houses are on an absolutely equal footing, and bills are introduced into one or the other simply because of reasons of practical convenience. The Federal parliament meets, at least, once a year, in Bern, the Federal capital. The *Federal executive* (*Bundesrat* or *conseil fédéral*) was set up in 1848 and is composed of seven members, who are elected for three years by the two houses of the Federal legislature, sitting together as a congress, but no two members may belong to the same canton. The Federal parliament annually names the president (*Bundespräsident* or *président de la confédération*) and the vice-president, so that the former is really but the chairman of a committee, and not in any way like the American president. The Federal president always holds the foreign portfolio (the "political department"), the other portfolios being annually redistributed among the other members, but all decisions proceed from the council as a whole. The Federal councillors cannot be at the same time members of either house of the Federal parliament, though they may speak or introduce motions (but not vote) in either house. The *Federal Supreme Court* (*Bundesgericht* or *tribunal fédéral*) was created by the Federal Constitution of 1874 and is (since 1904) composed of 19 full members (plus 9 substitutes), all elected by the two houses of the Federal parliament, sitting together and holding office for six years; the Federal parliament also elects every two years the president and vice-president of the Federal tribunal. Its seat is at Lausanne. Its jurisdiction extends to disputes between the Confederation, the cantons, and private individuals, so far as these differences refer to Federal matters. An appeal lies in some cases (not too clearly distinguished) to the Federal council, and in some to the two houses of the Federal legislature sitting together. As to the referendum and initiative (whether as to the revision of the constitution or as to bills) see REFERENDUM.

It was natural that, as the members of the Swiss Confederation were drawn closer and closer together, there should arise the idea of a *Federal code* as distinguished from the manifold cantonal legal systems. The Federal Constitution of 1874 conferred on the Federal authorities the power to legislate on certain defined legal subjects, and advantage was taken of this to revise and codify the Law of Obligations (1881) and the Law of Bankruptcy (1889). The success of these attempts led to the adoption by the Swiss people (1898) of new constitutional articles, extending the powers of the Federal authorities to the other departments of civil law and also to criminal law. Drafts carefully prepared by commissions of specialists were slowly considered during nearly two years by the two houses of the Federal parliament, which finally adopted the civil code on the 10th of December 1907, and it was expected that by 1912 both a complete Federal civil code and a complete Federal criminal code would come into operation.

Before 1848 there was scarcely such a thing as *Federal finances* for there was no strong central Federal authority. As the power of those authorities increased, so naturally did their expenditure and receipts. In 1849 the receipts were nearly £240,000, as against an expenditure of £260,000. By 1873 each had risen to rather over £1,250,000, while in 1883 they just overtopped £2,000,000 sterling each, and in 1900 the receipts were just over £4,000,000 sterling, as against an expenditure of nearly £4,000,000. The figures for 1907 are £5,750,000 as against just over £5,500,000, and are the highest yet recorded. The funded Federal debt rose from a modest £150,000 in 1849 to rather over £2,000,000 in 1891, and rather over £4,000,000 in 1903, standing in 1905 at £3,250,000.

By the Federal Constitution of 1848 the *post office* was made a Federal attribute, and the first Federal law on the subject was passed in 1849 (postage stamps within the country in 1850, for foreign lands in 1854, and post-cards in 1870), while a Federal law of 1851 extended this privilege to the electric telegraph, so that in 1852 the first line was opened with thirty-four offices. In the Federal Constitution of 1874 both branches are declared to fall within the jurisdiction of the Confederation, while in 1878 this privilege was extended to the newly invented telephone. Inviolability of communications in all three cases is guaranteed.

In 1891 the Swiss people accepted the principle of a *state bank* with a monopoly of note issue. A first scheme was rejected by a popular vote in 1897, but a second was more successful in 1905. The "Swiss National Bank" was actually opened on the 20th of June 1907, its two chief seats being at Zürich and at Bern. It has a capital of £2,000,000 sterling, divided into 100,000 shares. Two-fifths of this capital is reserved to the cantons in proportion to their population in 1900, and two-fifths were taken up by public subscription in June 1906. The remaining fifth was reserved to the existing thirty-six banks in Switzerland (all founded between 1834 and 1900), which have hitherto enjoyed the right of issuing notes. It was stipulated that within three years of the opening of the National Bank all notes issued by these thirty-six banks must be withdrawn, and many had by 1907 taken this course in anticipation.

There is no "established Swiss Church" recognized by the Federal Constitution, but there may be one or more "established churches" in any canton. The Federal Constitution of 1874 guarantees full religious liberty and freedom of worship, not being contrary to morals and the public peace, as well as exemption from any compulsory church rates (arts. 49 and 50). But it repeats, with fresh pricks (art. 51), the provision of the Constitution of 1848 by which the Jesuits and all affiliated religious orders are forbidden to settle in Switzerland, extending this prohibition to any other orders that may endanger the safety of the state or the public peace. It also introduces a new article (No. 52) forbidding the erection of new religious orders or new monasteries or the re-establishment of old ones, and also a new clause (last part of art. 50) by which the erection of new bishoprics on Swiss soil is subject to the approval of the Federal authorities. The Jesuit article was due to the "Sonderbund" War of 1847, and the rest of this exceptional legislation to the "Kulturkampf" which raged in Switzerland in 1872–1874. The Protestants form rather over three-fifths of the population, but have the majority in 10½ of the 22 cantons only. In the German-speaking cantons they are Zwinglians, and in the French-speaking cantons Calvinists, though in neither case of the original and orthodox shade. The Protestants alone are "established" in the Outer Rhodes of Appenzell; while the Romanists alone are "established" in 7½ cantons (Lucerne, Uri, Schwyz, Unterwalden, Zug, Ticino, the Valais, and the Inner Rhodes of Appenzell), but only jointly in the 3 other cantons (Fribourg, St Gall and Soleure) in which they are in a majority. In June 1907 Geneva decided on the complete separation of church and state, and now stands alone in Switzerland in not having any "established church" at all (previously it had two—Protestants and Christian Catholics). In the other 21 cantons, the Protestants and Romanists are jointly "established" in 11½, as are the Protestants and the Christian Catholics in 1½, in which the Christian Catholics take the place of the Romanists. Thus out of the 21 cantons with "established churches" (*Landeskirchen* or *églises nationales*) the Protestants are solely or jointly "established" in 13½, and the Romanists in 19 (not in Bern, Urban Basel and the Outer Rhodes of Appenzell), while the Christian Catholics are recognized in 7 cantons, in two of which (Basel and Neuchâtel) they are also "endowed." The case of Neuchâtel is particularly striking, as it has three "established churches" (Protestants, Romanists and Christian Catholics), while there the Jewish rabbis, as well as the *pasteurs* of the Free Evangelical Church, are exempt from military service. Besides a few parishes in Bern there are also three "Evangelical Free Churches" (*Églises libres*), viz. in Vaud (since 1847), in Geneva (since 1848) and in Neuchâtel (since 1873). The Romanists have five diocesan bishops in Switzerland—Sion (founded in the 4th century), Geneva (4th century, Basel (4th century, but reorganized in 1828), Coire (5th century), Lausanne (6th century), and St Gall (till 1824 part of the bishopric of Constance, and a separate see since 1847). There are besides the sees of Lugano (erected in 1888 for Italian Switzerland—till then in Milan or Como—but united for the present to the see of Basel, though administered by a suffragan bishop) and Bethlehem (a see *in partibus*, annexed in 1840 to the abbacy of St Maurice in the Valais). The Christian Catholics (who resemble the Old Catholics in Germany) split off from the Romanists in 1874 on the question of papal infallibility (in Bern and Geneva politics also played a great part), and since 1876 have had a bishop of their own (consecrated by the German Old Catholic, Bishop Reinkens), who resides in Bern, but bears no diocesan title. The Christian Catholics (who in the census are counted with the Romanists) are strongest in Bern, Soleure and Geneva, while their number in 1906 was estimated variously at from twenty to thirty-four thousand—they have 38 parishes (10 being in French-speaking Switzerland) and some 57 pastors. There are still a few monasteries in Switzerland which have escaped suppression. The principal are the Benedictine houses of Disentis (founded in the 7th century by the Irish monk Sigisbert), Einsiedeln (*q.v.*; 10th century) and Engelberg (*q.v.*; 12th century) as well as the houses of Austin Canons at St Maurice (held by them since 1128, though the house was founded by Benedictines in the 6th century) and on the Great St Bernard (11th century).

Education.—Education of all grades is well cared for in Switzerland, and large sums are annually spent on it by the cantons and the communes, with substantial grants from the Confederation (these last in 1905 were about £224,000), so far as regards primary and higher education. Four classes of educational establishments exist.

a. In the case of the *primary education*, the Confederation has the oversight (Federal Constitution of 1874, art. 27), but the cantons the administration. It is laid down that in the case of the public primary schools four principles must be observed by the cantons: the instruction given must be sufficient, it must be under state (*i.e.* lay) management (ecclesiastics as such can have no share in it), attendance must be compulsory, and the instruction must be gratuitous, while members of all religions must be able to frequent the schools without offence to their belief or consciences (this is interpreted to mean that the general instruction given must be undenominational, while if any denominational instruction is given attendance at it must not be made compulsory). By an amendment to the Federal Constitution adopted in 1902 the Confederation is empowered to make grants in aid in the case of primary schools, while a Federal law of 1903, regulating such grants to be appropriated solely to certain specified purposes, provides that the term "primary schools" shall include continuation schools if attendance is compulsory. The cantons organize primary education in their territories, delegating local arrangements (under the control of a cantonal inspector) to a committee (*Schulkommission*) elected *ad hoc* in each commune, so that it is not a committee of the communal council. The general principles laid down by the Confederation are elaborated into laws by each canton, while the communal councils pass by-laws. Hence there is a great variety in details between canton and canton. The school age varies from 6 to 16 (for younger scholars there are voluntary kindergarten schools or *écoles enfantines*), and attendance during this period is compulsory, it not being possible to obtain exemption by passing a certain standard. Two-thirds of the schools are "mixed"; in the towns, however, boys are often separated from girls. The teachers (who must hold a cantonal certificate of efficiency) are chosen by the Schulkommission from among the candidates who apply for the vacant post, but are elected and paid by the communal council. Religious tests prevail as to teachers, who must declare the religion they profess, and are required to impart the religious instruction in the school, this being compulsory on the children professing the religion that is in the majority in that particular commune—consequently a Protestant teacher would never be appointed in a Romanist school or vice versa. The religious teaching occupies an hour (always at the beginning of the school hours) thrice a week, while special dogmatic instruction is imparted by the pastor, outside the school-house as a rule, or in a room specially set apart therein. The pastor is *ex officio* president of the Schulkommission, while the religious teaching in school is based on a special "school Bible," containing short versions of the chief events in Bible history. The exact curriculum (code) is prescribed by the canton, and also the number of hours during which the school must be open annually, but the precise repartition of these is left to the local Schulkommission. The attendance registers kept by the teachers are submitted to the Schulkommission, which takes measures against truant children or negligent parents by means of a written warning, followed (if need be) by a summons before a court. The treasurer of the Schulkommission receives and distributes the money contributions of the cantons (including the grant in aid from the Confederation) and also of the communes, or of benevolent private individuals. The school hours are as a rule four hours (from 7 a.m. in summer and 8 a.m. in winter) in the morning and (in the winter) three hours in the afternoon, but on two afternoons in the week there is a sewing school for the girls, the boys being then free. There are no regular half-holidays. Private schools are permitted, but receive no financial aid from the outside, while the teacher must hold a certificate of efficiency as in the state schools, must adopt the same curriculum, and is subject to the by-laws made by the Schulkommission. On the other hand he is not bound by any conscience clause and can charge fees. A cantonal inspector examines each school (of either class) annually and reports to the cantonal educational authorities, who point out any deficiencies to the local Schulkommission, which must remedy them. There is no payment by results, nor do the money contributions (from any source) depend on the number of attendances made, though of course they are more or less in proportion to the number of scholars attending that particular school. Some favour the idea of making the primary schools wholly dependent financially on the Confederation. This course has obvious conveniences, but a first attempt was defeated in 1882, and the scheme is still opposed, mainly on the ground that it would seriously impair the principle of cantonal sovereignty, and immensely strengthen the power of the Federal educational authorities. By the law of 1903 the quota of the Federal subvention was fixed at sixpence per head of the resident population of each canton, but in the case of 6½ cantons (the poorer ones) an extra twopence was added.

b. The *secondary schools* are meant on the one side to help those scholars of the primary schools who desire to increase their knowledge though without any idea of going on to higher studies, and on the other to prepare certain students for entrance into the middle schools. The attendance everywhere is optional, save in the city of Basel, where it is compulsory. These schools vary very much from canton to canton. The course of studies extends over two to four years, and students are admitted at ages from ten upwards. The curriculum includes the elements of the classical and modern languages, of mathematics, and of the natural sciences. They receive no Federal subvention, but are supported by the cantons and the communes. In 1905 the cantons contributed £20,000 less than the communes to the total cost of about £234,000.

c. Under the general name of *middle schools* (*Mittelschulen* or *écoles moyennes*) the Swiss include a variety of educational establishments, which fall roughly under two heads:—

1. Technical schools (like those at Bienne and Winterthur) and schools for instruction in various professions (commerce, agriculture, forestry and the training colleges for teachers).
2. Grammar schools, colleges and cantonal schools, which in some cases prepare for the universities and in some cases do not.

The expenses of both classes fall mainly on the cantons (in 1905 about £300,000 to £130,000 from the communes), who for the former class (including certain departments of the second) receive a grant in aid from the Confederation—in 1905 about £84,500.

d. As regards the *higher education* the Federal Constitution of 1874 (art. 27) empowered the Confederation to erect and support, besides the existing Federal Polytechnic School (opened at Zürich in 1855, having been founded by virtue of art. 22 of the Federal Constitution of 1848), a Federal university (this has not yet been done) and other establishments for the higher education (see *c.* 1 above). This clause would seem to authorize the Confederation to make grants in aid of the cantonal universities, but as yet this has not been done, while the cantons are in no hurry to give up their local universities. There are seven full universities in Switzerland—Basel (founded in 1460), Zürich (1833), Bern (1834), Geneva (1873, founded in 1559 as an académie), Fribourg (international Catholic, founded in 1889), Lausanne (1890, founded in 1537 as an académie) and Neuchâtel (existed 1840–1848, refounded in 1866, and raised from the rank of an académie to that of a university in 1909). There is besides a law school at Sion (existed 1807–1810, refounded in 1824). In general they each (save Sion, of course) have four faculties—theology, medicine, law and philosophy. Fribourg and Neuchâtel both lack a medical faculty, while Zürich and Bern have distinct faculties for veterinary medicine, and Zürich a special one for dentistry (in Geneva there is a school of dentistry), while Geneva and Neuchâtel support observatories. The theological faculty is in every case Protestant, save that in Fribourg there is only a Romanist faculty (192 students in 1907), while Bern has both a Protestant faculty and also a Christian Catholic faculty (11 students in 1907), but no Romanist faculty, despite the fact that the Romanists (mainly in the Bernese Jura) form about one-sixth of the population, while there are not very many Christian Catholics. These eight academical institutions were maintained by the cantons at a cost in 1905 of about £155,000, while in the winter session of 1906 the total number of matriculated students (of whom 3784 were non-Swiss) was 6444 (of whom 1904 were women—Fribourg does not receive them), besides 2077 "hearers"—in all 8521. The largest institution was Bern (1626 matriculated students) and the smallest Neuchâtel (163). The Federal Polytechnic School is fixed at Zürich and now comprises seven departments—architecture, engineering, industrial mechanics, industrial chemistry, agriculture and forestry, training of teachers in mathematics, physics and the natural sciences, and military science, besides a department for philosophy and political science. It enjoys a very high reputation and is much frequented by non-Swiss, who in the winter session of 1905–1906 numbered 522 out of the 1325 matriculated students (women are not admitted). In 1905 the cost of the maintenance of the school (which falls entirely upon the Confederation) was about £56,000.

Army.—The Swiss army is a purely militia force, receiving only periodical training (so far as regards men between 20 and 48 years of age), based upon the principle of universal compulsory personal military service. Till 1848 the cantons alone raised, armed, equipped and trained all military units and nominated the officers. By the Federal Constitution of 1848 (art. 20) the Confederation was entrusted with the training of the engineers, the artillery and the cavalry, with the education of instructors for all other arms, and with the higher training of all arms, while it was empowered to found military schools, to organize general military manœuvres, and to supply a part of the war *matériel*. The Confederation, too, was given the supervision of the training of the infantry, as well as the furnishing, the construction and the maintenance of all war *matériel*, which the cantons were bound to supply to the Confederation. The Federal Constitution of 1874 marked an advance on that of 1848 as to the following points. The principle of universal military service and the organization of the Federal army were developed according to the proportion of the population capable of bearing arms (in contradistinction to the 1848 system, art. 19, of fixed contingents in the proportion of 3 to every 100 men of the population of each canton); the entire military training and arming of these men and the cost of their uniform and equipment were taken over by the Confederation, which, too, supervised the military administration of the cantons. The uniform, equipment and weapons of the men were to be free of cost to them, while compensation was due from the Confederation to the families of those killed or permanently injured in the course of their military service, as well as to the invalids themselves. There thus remained to the cantons the raising of all the infantry units and of most of the cavalry and artillery units as well as the nomination of the officers of all arms; all these acts were subject to the supervision of the Confederation and had to be in accordance with Federal laws and regulations. An attempt made in 1895 to extend still further the sphere of action of the Confederation in military matters was rejected by a vote of the Swiss people. Thus the present system rests partly on the 1874 Constitution, and partly on the new military law, passed by the Federal parliament on the 12th of April 1907.

a. The 1874 Constitution forbids the maintenance of any standing army (art. 13), and also (art. 11) the practice (formerly very widespread) of hiring out contingents of mercenary soldiers by the Confederation or the cantons to foreign powers ("military capitulations"). The Federal government can, at or without the request of any canton, repress any disturbances within Switzerland by means of Federal troops, the cantons being bound to allow these free passage over their territory (arts. 16–17). By art. 18 every Swiss male citizen is subject to the obligation of personal military service (the families of those killed or permanently injured in the course of active Federal service as well as the invalids themselves are provided for by the Confederation), and the tax for those exempted is to be fixed by a Federal law, while every recruit receives free of cost his first uniform, equipment and weapons. Art. 16

provides that the Confederation has control of the Federal army and of the war *matériel*, the cantons being only allowed certain defined rights within their respective territories. By art. 20 the limits of the jurisdiction of the Confederation and of the cantons are defined. The Confederation has the sole right of legislation in military matters, but the execution of these laws is in the hands of the cantons, though under Federal supervision, while all branches of military training and arming are handed over to the Confederation; on the other hand, the cantons supply and keep up the equipment and the uniforms of the soldiers, though these expenses are reimbursed by the Confederation according to a certain scale fixed by Federal regulations to be made later on. Art. 21 enacts that, where military considerations do not stand in the way, the military units are to be formed of men of the same canton, but the actual raising of these units and the maintenance of their numbers, as well as the nomination and the promotion of the officers, belong to the cantons, subject to certain general principles to be laid down by the Confederation. Finally, the Confederation has (art. 22) the right of using or acquiring military drill grounds, buildings, &c., belonging to the cantons on payment of moderate compensation according to principles to be laid down in a Federal law. It will thus be seen that the Swiss army is by no means wholly in the hands of the Federal authorities, the cantons still having a large share in its management, though the military department of the Federal executive has the ultimate control and pays most of the military expenses. In fact it has been said in jest that the coat of a soldier belongs to his canton and his rifle to the Confederation.

b. After much discussion and careful consideration of the opinions of many experts, the Federal law of 1907 was enacted, by which more uniformity was introduced into administrative matters and the whole system remodelled, of course according to the general principles formulated in the Federal Constitution of 1874 and summarized under *a*.

The following is a bird's-eye view of the actual organization of the Swiss army. Every Swiss male citizen is bound to render personal military service between the ages of twenty and forty-eight. Certain classes are exempt, such as high Federal officials, clergymen (not being military chaplains), officials of hospitals and prisons, as well as custom-house officials and policemen and officials of public means of communication, but in the latter case only those whose services would be indispensable in time of war, *e.g.* post office, telegraph, telephone, railway and steamer employés (all exempted before 1907)—custom-house men, policemen and the officials last named must have had a first period of training before they are exempt. Those who are totally disqualified for any reason must, till the age of forty, pay an extra tax of 6 francs a head, plus 1½ francs on every 1000 francs of their net property, and 1½ francs on every 100 francs of their net income, the maximum tax that can be levied in any particular case being 3000 francs a year (property under 1000 francs and the first 600 francs of income are free from this tax, which is only levied as to its half in case of the men in the Landwehr): this tax is equally divided between the Confederation and the cantons, its total yield in 1905 being about £171,000. The cantonal authorities muster in certain fixed centres their young men of twenty years, who must appear personally in order to submit themselves at the hands of the Federal officials to a medical examination, a literary examination (reading, arithmetic, elementary Swiss geography and history, and the composition of a short written essay), as well as (since 1905) pass certain elementary gymnastic tests (a long jump of at least 8 ft., lifting at least four times a weight of about 37 lb in both hands at once, and running about 80 yds. in under 14 seconds), different marks being given according to the degree of proficiency in these literary and gymnastic departments. Those falling below a certain standard—bodily, mental or muscular—are exempted, but may be "postponed" for not more than four years, in hopes that before that date the desired standard will be attained. If not totally disqualified (in that case they pay a tax) they may be incorporated not in the territorial army, but in the auxiliary forces (*e.g.* pioneers, hospital, commissariat, intelligence and transport departments). The cantons (under Federal supervision) see that the lads, while still at school, receive a gymnastic training, while the Confederation makes money grants to societies which aim at preparing lads after leaving school for their military service, whether by stimulating bodily training or the practice of rifle shooting, in which case rifles, ammunition and equipment are supplied free—in all these cases the attendance of the lads is purely voluntary. In some cantons the young men, between the ages of eighteen and twenty, are *required* to attend a night school (in order to rub up their school knowledge) for sixty hours a winter for two winters, the teacher being paid by the Confederation and the lads being under military law. Naturally the lads from the large towns and the more prosperous cantons do best in the literary examination and those who belong to gymnastic societies in the gymnastic tests, though sheer bodily untrained strength avails much in the lifting of weights. In 1906 26,808 young men of twenty years of age were examined (this is exclusive of older men then first mustered). Of this number 14,045 (52·4%) were at once enrolled as recruits, 3497 (13%) were "postponed" for one or two years, and 9266 (34·6%) were exempted wholly—these ratios vary but little, for the standard is kept rather high, partly owing to considerations of expense, so that a young fellow of twenty who becomes a "recruit" at once may be taken to be distinctly above the average in bodily and mental qualities. By the new law of 1907 the army is divided into three (not, as previously, four) classes—the *Auszug* or *élite* (men from twenty to thirty-two), the *Landwehr* (men between thirty-three and forty) and the *Landsturm* or *réserve* (men between forty-one and forty-eight). The recruits serve for different periods during their first year according to the arm of the service into which they are incorporated—infantry and engineers sixty-five days, artillery and garrison troops seventy-five days and cavalry ninety days, while those in the auxiliary troops serve but sixty days. Soldiers in the Élite are called out seven times during their term of service for a period of eleven days a year (fourteen days for the artillery and garrison troops), while the Landwehr is only called out once for a training period of eleven days. Cavalry men serve ten years in the Élite (no service in the Landwehr), and during that period are called out eight times for a training period of eleven days a year. Between the ages of twenty and forty each soldier must attain a certain proficiency in marksmanship (at least 30 points out of 90 in 10 shots), while there is an annual inspection (by cantonal officials) of arms, uniform and equipment. The Confederation also makes money grants to rifle societies, which in 1906 numbered 3732, had 220,951 members (all soldiers between twenty and forty must be members), and received Federal grants to the amount of about £13,500. Rifle and uniform become the full property of the soldier after he has completed his full term of service. Officers serve in the Élite till thirty-eight years of age, and in the Landwehr till forty-four (in the case of officers on the staff the service lasts till forty-eight years of age), while they remain in the Landsturm till fifty-two years of age. The Swiss army is made up (according to the new law of 1907) of a staff, composed of all the commanding officers on active service from the rank of major upwards (in this as in all the following cases the actual number is to be fixed by a Federal law), the general staff, the army service corps (post office, telegraph, railways, motor cars, chaplains, police, courts of justice, secretaries, &c., and the auxiliary services), while the soldiers proper are divided into a number of classes—infantry (including sharpshooters and cyclists), cavalry, artillery (including the mountain batteries), engineers (including sappers and railway labourers), garrison troops, the medical, veterinary (veterinary surgeons and farriers), commissariat and transport services (drivers and leaders of laden horses and mules). On the first of January 1907 (still under the old system) the numbers of the Swiss army were as follows: the Élite had 139,514 (of which 104,263 were infantry, 5183 cavalry, 18,544 artillery and 5567 engineers), and the Landwehr 93,163 (including 67,955 infantry, 4378 cavalry, 13,332 artillery and 4313 engineers)—making thus a total of 232,677 men between the ages of twenty and forty-four years of age (17,221 infantry, 9561 cavalry, 31,866 artillery and 9880 engineers). To this total must be added 44,294 men in the armed Landsturm (forty-five to fifty years of age) and 262,138 auxiliary troops (pioneers, workmen in military establishments, medical, commissariat and transport departments, police, firemen, clerks, and men at a military dépôt). The total of the Landsturm and the auxiliary services is 306,432, so that a grand total is 539,109 men (under the old system officers served in the Landwehr till forty-eight, and in the Landsturm till fifty-five). The total expenses of the Swiss army rose from £928,000 in 1896 to £1,400,000 in 1906. Rifles are manufactured in Bern, ammunition at Thun and at Altdorf, uniforms are made in Bern, and the cavalry remount dépôt is at Thun, which is also the chief artillery centre of Switzerland. There is a department for military science at the Federal Polytechnic School at Zürich, one section being meant for students in general, and the other specially for officers. (W. A. B. C.)

History

The Swiss Confederation is made up of twenty-two small states, differing from each other in nearly every point—religious, political, social, industrial, physical and linguistic; yet it forms a nation the patriotism of whose members is universally acknowledged. History alone can supply us with the key to this puzzle; but Swiss history, while thus essential if we could thoroughly grasp the nature of the Confederation, is very intricate and very local. A firm hold on a few guiding principles is therefore most desirable, and of these there are three which we must always bear in mind. (1) The first to be mentioned is *the connexion of Swiss history with that of the Empire.* Swiss history is largely the history of the drawing together of bits of each of the imperial kingdoms (Germany, Italy and Burgundy) for common defence against a common foe—the Habsburgs; and, when this family have secured to themselves the permanent possession of the Empire, the Swiss League little by little wins its independence of the Empire, practically in 1499, formally in 1648. Originally a member of the Empire, the Confederation becomes first an ally, then merely a friend. (2) The second is *the German origin and nature of the Confederation.* Round a German nucleus (the three Forest districts) there gradually gather other German districts; the Confederation is exclusively German (save partially in the case of Fribourg, in which after its admission in 1481 Teutonic influences gradually supplanted the Romance speech); and it is not till 1803 and 1815 that its French- and Italian-speaking "subjects" are raised to political equality with their former masters, and that the Romonsch-speaking Leagues of Raetia (Graubünden) pass from the status of an ally to that of a member of the Confederation. (3) Swiss history is *a study in federalism*. Based on the defensive alliances of 1291 and 1315 between the three Forest districts, the Confederation is enlarged by the admission of other districts and towns, all leagued with the original three members, but not necessarily with each other. Hence great difficulties are encountered in looking after common interests, in maintaining any real union; the Diet was merely an assembly of ambassadors with powers very strictly limited by their instructions, and there was no central executive authority. The Confederation is a *Staatenbund*, or permanent alliance of several small states. After the break-up of the old system in 1798 we see the idea of a *Bundesstaat*, or an organized state with a central legislative, executive and judiciary, work its way to the front, an idea which is gradually realized in the Constitutions of 1848 and 1874. The whole constitutional history of the Confederation is summed up in this transition to a federal state, which, while a single state in its foreign relations, in home matters maintains the more or less absolute independence of its several members.

Swiss history falls naturally into five great divisions: (1) the origins of the Confederation—up to 1291 (for the legendary origin see TELL, WILLIAM); (2) the shaking off dependence on the Habsburgs—up to 1394 (1474); (3) the shaking off dependence on the Empire—up to 1499 (1648); (4) the period of religious divisions and French influence—up to 1814; (5) the construction of an independent state as embodied in the Constitutions of 1848 and 1874.

Early History of the Three Lands.

1. On the 1st of August 1291 the men of the valley of Uri (*homines vallis Uraniae*), the free community of the valley of Schwyz (*universitas vallis de Switz*), and the association of the men of the lower valley or Nidwalden (*communitas hominum intramontanorum vallis inferioris*)—Obwalden or the upper valley is not mentioned in the text, though it is named on the seal appended—formed an Everlasting League for the purpose of self-defence against all who should attack or trouble them, a league which is expressly stated to be a confirmation of a former one (*antiquam confederationis formam juramento vallatam presentibus innovando*). This league was the foundation of the Swiss Confederation.

What were these districts? and why at this particular moment was it necessary for them to form a defensive league? The legal and political conditions of each were very different. (*a*) In 853 Louis the German granted (*inter alia*) all his lands (and the rights annexed to them) situated in the *pagellus Uraniae* to the convent of Sts Felix and Regula in Zürich (the present Fraumünster), of which his daughter Hildegard was the first abbess, and gave to this district the privilege of exemption from all jurisdiction save that of the king (*Reichsfreiheit*), so that though locally within the Zürichgau it was not subject to its count, the king's deputy. The abbey thus became possessed of the greater part of the valley of the Reuss between the present Devil's Bridge and the Lake of Lucerne, for the upper valley (Urseren) belonged at that time to the abbey of Disentis in the Rhine valley, and did not become permanently allied with Uri till 1410. The privileged position of the abbey tenants gradually led the other men of the valley to "commend" themselves to the abbey, whether they were tenants of other lords or free men as in the Schächenthal. The meeting of all the inhabitants of the valley, for purposes connected with the customary cultivation of the soil according to fixed rules and methods, served to prepare them for the enjoyment of full political liberty in later days. The important post of "protector" (*advocatus* or *vogt*) of the abbey was given to one family after another by the emperor as a sign of trust; but when, on the extinction of the house of Zäringen in 1218, the office was granted to the Habsburgs, the protests of the abbey tenants, who feared the rapidly rising power of that family, and perhaps also the desire of the German king to obtain command of the St Gotthard Pass (of which the first authentic mention occurs about 1236, when of course it could only be traversed on foot), led to the recall of the grant in 1231, the valley being thus restored to its original privileged position, and depending immediately on the king. (*b*) In Schwyz (first mentioned in 972) we must distinguish between the districts west and east of Steinen. In the former the land was in the hands of many nobles, amongst whom were the Habsburgs; in the latter there was, at the foot of the Mythen, a free community of men governing themselves and cultivating their land in common; both, however, were politically subject to the king's delegates, the counts of the Zürichgau, who after 1173 were the ever-advancing Habsburgs. But in 1240 the free community of Schwyz obtained from the emperor Frederick II. a charter which removed them from the jurisdiction of the counts, placing them in immediate dependence on the king, like the abbey men of Uri. In a few years, however, the Habsburgs contrived to dispense with this charter in practice. (*c*) In Unterwalden things were very different. The upper valley (Obwalden or Sarnen), like the lower (Nidwalden or Stans), formed part of the Zürichgau, while in both the soil was owned by many ecclesiastical and lay lords, among them being the Habsburgs and the Alsatian abbey of Murbach. Hence in this district there were privileged tenants, but no free community, and no centre of unity, and this explains why Obwalden and Nidwalden won their way upwards so much more slowly than their neighbours in Uri and Schwyz. Thus the early history and legal position of these three districts was very far from being the same. In Uri the Habsburgs, save for a brief space, had absolutely no rights; while in Schwyz, Obwalden and Nidwalden they were also, as counts of the Zürichgau, the representatives of the king.

The League of 1291.

The Habsburgs had been steadily rising for many years from the position of an unimportant family in the Aargau to that of a powerful clan of large landed proprietors in Swabia and Alsace, and had attained a certain political importance as counts of the Zürichgau and Aargau. In one or both qualities the cadet or Laufenburg line, to which the family estates in the Forest districts round the Lake of Lucerne had fallen on the division of the inheritance in 1232, seem to have exercised their legal rights in a harsh manner. In 1240 the free men of Schwyz obtained protection from the emperor, and in 1244 we hear of the castle of New Habsburg, built by the Habsburgs on a promontory jutting out into the lake not far from Lucerne, with the object of enforcing their real or pretended rights. It is therefore not a matter for surprise that when, after the excommunication and deposition of Frederick II. by Innocent IV. at the Council of Lyons in 1245, the head of the cadet line of Habsburg sided with the pope, some of the men of the Forest districts should rally round the emperor. Schwyz joined Sarnen and Lucerne (though Uri and Obwalden supported the pope); the castle of New Habsburg was reduced to its present ruined state; and in 1247 the men of Schwyz, Sarnen and Lucerne were threatened by the pope with excommunication if they persisted in upholding the emperor and defying their hereditary lords the counts of Habsburg. The rapid decline of Frederick's cause soon enabled the Habsburgs to regain their authority in these districts. Yet these obscure risings have an historical interest, for they are the foundation in fact (so far as they have any) of the legendary stories of Habsburg oppression told of and by a later age. After this temporary check the power of the Habsburgs continued to increase rapidly. In 1273 the head of the cadet line sold all his lands and rights in the Forest districts to the head of the elder or Alsatian line, Rudolph, who a few months later was elected to the imperial throne, in virtue of which he acquired for his family in 1282 the duchy of Austria, which now for the first time became connected with the Habsburgs. Rudolph recognized the privileges of Uri but not those of Schwyz; and, as he now united in his own person the characters of emperor, count of the Zürichgau, and landowner in the Forest districts (a name occurring first in the 14th century), such a union of offices might be expected to result in a confusion of rights. On the 16th of April 1291 Rudolph bought from the abbey of Murbach in Alsace (of which he was "advocate") all its rights over the town of Lucerne and the abbey estates in Unterwalden. It thus seemed probable that the other Forest districts would be shut off from their natural means of communication with the outer world by way of the lake. Rudolph's death, on the 15th of July of the same year, cleared the way, and a fortnight later (August 1) the Everlasting League was made between the men of Uri, Schwyz and Nidwalden (the words *et vallis superioris*, *i.e.* Obwalden, were inserted, perhaps between the time of the drawing up of the document, the text of which does not mention Obwalden, and the moment of its sealing on the original seal of Nidwalden) for the purpose of self-defence against a common foe. We do not know the names of the delegates of each valley who concluded the treaty, nor the place where it was made, nor have we any account of the deliberations of which it was the result. The common seal—that great outward sign of the right of a corporate body to act in its own name—appears first in Uri in 1243, in Schwyz in 1281, in Unterwalden not till this very document of 1291; yet, despite the great differences in their political status, they all joined in concluding this League, and confirmed it by their separate seals, thereby laying claim on behalf of their union to an independent existence. Besides promises of aid and assistance in the case of attack, they agree to punish great criminals by their own authority, but advise that, in minor cases and in all civil cases, each man should recognize the "judex" to whom he owes suit, engaging that the Confederates will, in case of need, enforce the decisions of the "judex." At the same time they unanimously refuse to recognize any "judex" who has bought his charge or is a stranger to the valleys. All disputes between the parties to the treaty are, as far as possible, to be settled by a reference to arbiters, a principle which remained in force for over six hundred years. "Judex" is a general term for any local official, especially the chief of the community, whether named by the lord or by the community; and, as earlier in the same year Rudolph had promised the men of Schwyz not to force upon them a "judex" belonging to the class of serfs, we may conjecture from this very decided protest that the chief source of disagreement was in the matter of the jurisdictions of the lord and the free community, and that some recent event in Schwyz led it to insist on the insertion of this provision. It is stipulated also that every man shall be bound to obey his own lord "convenienter," or so far as is fitting and right. The *antiqua confoederatio* mentioned in this document was probably merely an ordinary agreement to preserve the peace in that particular district, made probably during the interregnum (1254–1273) in the Empire.

Morgarten and the League of 1315.

2. In the struggle for the Empire, which extended over the years following the conclusion of the League of 1291, we find that the Confederates supported without exception the anti-Habsburg candidate. On the 16th of October 1291 Uri and Schwyz allied themselves with Zürich, and joined the general rising in Swabia against Albert, the new head of the house of Habsburg. It soon failed, but hopes revived when in 1292 Adolf of Nassau was chosen emperor. In 1297 he confirmed to the free men of Schwyz their charter of 1240, and, strangely enough, confirmed the same charter to Uri, instead of their own of 1231. It is in his reign that we have the first recorded meeting of the "Landsgemeinde" (or legislative assembly) of Schwyz (1294). But in 1298 Albert of Habsburg himself was elected to the Empire. His rule was strict and severe, though not oppressive. He did not indeed confirm the charters of Uri or of Schwyz, but he did not attack the ancient rights of the former, and in the latter he exercised his rights as a landowner and did not abuse his political rights as emperor or as count. In Unterwalden we find that in 1304 the two valleys were joined together under a common administrator (the local deputy of the count)—a great step forward to permanent union. The stories of Albert's tyrannical actions in the Forest districts are not heard of till two centuries later, though no doubt the union of offices in his person was a permanent source of alarm to the Confederation. It was in his time too that the "terrier" (or list of manors and estates, with enumeration of all quit rents, dues, &c., payable by the tenants to their lords) of all the Habsburg possessions in Upper Germany was begun, and it was on the point of being extended to Schwyz and Unterwalden when Albert was murdered (1308) and the election of Henry of Luxemburg roused the free men to resist the officials charged with the survey. Despite his promise to restore to the Habsburgs all rights enjoyed by them under his three predecessors (or maintain them in possession), Henry confirmed, on the 3rd of June 1309, to Uri and Schwyz their charters of 1297, and, for some unknown reason, confirmed to Unterwalden all the liberties granted by his predecessor, though as a matter of fact none had been granted. This charter, and the nomination of one royal bailiff to administer the three districts, had the effect of placing them all (despite historical differences) in an identical political position, and that the most privileged yet given to any of them—the freedom of the free community of Schwyz. A few days later the Confederates made a fresh treaty of alliance with Zürich; and in 1310 the emperor placed certain other inhabitants of Schwyz on the same privileged footing as the free community. The Habsburgs were put off with promises; and, though their request (1311) for an inquiry into their precise rights in Alsace and in the Forest districts was granted, no steps were taken to carry out this investigation. Thus in Henry's time the struggle was between the Empire and the Habsburgs as to the recognition of the rights of the latter, *not* between the Habsburgs and those dependent on them as landlords or counts.

On Henry's death in 1313 the electors hesitated long between Frederick the Handsome of Habsburg and Louis of Bavaria. The men of Schwyz seized this opportunity for making a wanton attack on the great abbey of Einsiedeln, with which they had a long-standing quarrel as to rights of pasture. The abbot caused them to be excommunicated, and Frederick (the choice of the minority of the electors), who was the hereditary "advocate" of the abbey, placed them under the ban of the Empire. Louis, to whom they appealed, removed the ban; on which Frederick issued a decree by which he restored to his family all their rights and possessions in *the three valleys* and Urseren, and charged his brother Leopold with the execution of this order. The Confederates hastily concluded alliances with Glarus, Urseren, Arth and Interlaken to protect themselves from attack on every side. Leopold collected a brilliant army at the Austrian town of Zug in order to attack Schwyz, while a body of troops was to take Unterwalden in the rear by way of the Brünig Pass. On the 15th of November 1315, Leopold with from 15,000 to 20,000 men moved forward along the shore of the Lake of Aegeri, intending to assail the town of Schwyz by climbing the slopes of Morgarten above the south-eastern end of the lake. There they were awaited by the valiant band of the Confederates from 1300 to 1500 strong. The march up the rugged and slippery slope threw the Austrian army into disarray, which became a rout and mad flight when huge boulders and trunks of trees were hurled from above by their foes, who charged down and drove them into the lake. Leopold fled in hot haste to Winterthur, and the attack by the Brünig was driven back by the men of Unterwalden. On the 9th of December 1315 representatives of the victorious highlanders met at Brunnen, on the Lake of Lucerne, not far from Schwyz, and renewed the Everlasting League of 1291. In their main lines the two documents are very similar, the later being chiefly an expansion of the earlier. That of 1315 is in German (in contrast to the 1291 League, which is in Latin), and has one or two striking clauses largely indebted to a decree issued by Zürich on the 24th of July 1291. None of the three districts or their dependents is to recognize a new lord without the consent and counsel of the rest. (This is probably meant to provide for an interregnum in or disputed election to the Empire, possibly for the chance of the election of a Habsburg.) Strict obedience in all lawful matters is to be rendered to the rightful lord in each case, unless he attacks or wrongs any of the Confederates, in which case they are to be free from all obligations. No negotiations, so long as the "Länder" have no lord, are to be entered on with outside powers, save by common agreement of all. Louis solemnly recognized and confirmed the new league in 1316, and in 1318 a truce was concluded between the Confederates and the Habsburgs, who treat with them on equal terms. The lands and rights annexed belonging to the Habsburgs in the Forest districts are fully recognized as they existed in the days of Henry of Luxemburg, and freedom of commerce is granted. But there is not one word about the *political* rights of the Habsburgs as counts of the Zürichgau and Aargau. This distinction gives the key to the whole history of the relations between the Confederates and Habsburgs; the rights of the latter as landowners are fully allowed, and till 1801 they possessed estates within the Confederation; it is their political rights which were always contested by the Swiss, who desired to rule themselves.

The League of Eight Members.

As early as 1320 we find the name "Switzerland" (*Sweicz*) (derived from Schwyz, which had always been the leader in the struggle) applied to the three Forest cantons, and in 1352 extended to the Confederation as a whole. But it was not till after Sempach (1386) that it came into popular use, the historian J. von Müller (1785) fixing the distinction between "Schweiz" (for the country) and "Schwyz" (for the canton), and it did not form the official name of the Confederation till 1803. (Officially in the middle ages and later the Confederation was named "les Ligues de la Haute Allemagne," or, as Commines, late in the 15th century, puts it, "les vieilles Ligues d'Allemagne qu'on appelle Suisses," while from *c.* 1452 onwards the people were called "Swiss"). This is in itself a proof of the great renown which the League won by its victory at Morgarten. Another is that as years go by we find other members admitted to the privileges of the original alliance of the three Forest districts. First to join the League (1332) was the neighbouring town of Lucerne, which had grown up round the monastery of St Leodegar or Leger (whence the place took its name), perhaps a colony, certainly a cell of the great house of Murbach in Alsace, under the rule of which the town remained till its sale in 1291 to the Habsburgs. This act of Lucerne was opposed by the house of Austria, but, despite the decision of certain chosen arbitrators in favour of the Habsburg claims, the town clung to the League with which it was connected by its natural position, and thus brought a new element into the pastoral association of the Forest districts, which now surrounded the entire Lake of Lucerne. Next, in 1351, came the ancient town of Zürich, which in 1218, on the extinction of the house of Zäringen, had become a free imperial city in which the abbess of the Fraumünster (the lady of Uri) had great influence, while in 1336 there had been a great civic revolution, headed by Rudolph Brun, which had raised the members of the craft gilds to a position in the municipal government of equal power with that of the patricians, who, however, did not cease intriguing to regain their lost privileges, so that Brun, after long hesitation, decided to throw in the lot of the town with the League rather than with Austria. In this way the League now advanced from the hilly country to the plains, though the terms of the treaty with Zürich did not bind it so closely to the Confederates as in the other cases (the right of making alliances apart from the League being reserved though the League was to rank before these), and hence rendered it possible for Zürich now and again to incline towards Austria in a fashion which did great hurt to its allies. In 1352 the League was enlarged by the admission of Glarus and Zug. Glarus belonged to the monastery of Säckingen on the Rhine (founded by the Irish monk Fridolin), of which the Habsburgs were "advocates," claiming therefore many rights over the valley, which refused to admit them, and joyfully received the Confederates who came to its aid; but it was placed on a lower footing than the other members of the League, being bound to obey their orders. Three weeks later the town and district of Zug, attacked by the League and abandoned by their Habsburg masters, joined the Confederation, forming a transition link between the civic and rural members of the League. The immediate occasion of the union of these two districts was the war begun by the Austrian duke against Zürich, which was ended by the Brandenburg peace of 1352, by which Glarus and Zug were to be restored to the Habsburgs, who also regained their rights over Lucerne. Zug was won for good by a bold stroke of the men of Schwyz in 1364, but it was not till the day of Näfels (1388) that Glarus recovered its lost freedom. These temporary losses and the treaty made by Brun of Zürich with Austria in 1356 were, however, far outweighed by the entrance into the League in 1353 of the famous town of Bern, which, founded in 1191 by Berthold V. of Zäringen, and endowed with great privileges, had become a free imperial city in 1218 on the extinction of the Zäringen dynasty. Founded for the purpose of bridling the turbulent feudal nobles around, many of whom had become citizens, Bern beat them back at Dornbühl (1298), and made a treaty with the Forest districts as early as 1323. In 1339, at the bloody fight of Laupen, she had broken the power of the nobles for ever, and in 1352 had been forced by a treaty with Austria to take part in the war against Zürich, but soon after the conclusion of peace entered the League as the ally of the three Forest districts, being thus only indirectly joined to Lucerne and Zürich. The special importance of the accession of Bern was that the League now began to spread to the west, and was thus brought into connexion for the first time with the French-speaking land of Savoy. The League thus numbered eight members, the fruits of Morgarten, and no further members were admitted till 1481, after the Burgundian War. But, in order thoroughly to understand the nature of the League, it must be remembered that, while each of the five new members was allied with the original nucleus—the three Forest districts—these five were not directly allied to one another: Lucerne was allied with Zürich and Zug; Zürich with Lucerne, Zug and Glarus; Glarus with Zürich; Zug with Lucerne and Zürich; Bern with no one except the three original members. The circumstances under which each entered the League can alone explain these very intricate relations.

Sempach.

After a short interval of peace the quarrels with Austria broke out afresh; all the members of the League, save the three Forest districts and Glarus, joined (1385) the great union of the south German cities; but their attention was soon called to events nearer home. Lucerne fretted much under the Austrian rule, received many Austrian subjects among her citizens, and refused to pay custom duties to the Austrian bailiff at Rothenburg, on the ground that she had the right of free traffic. An attack on the custom-house at Rothenburg, and the gift of the privileges of burghership to the discontented inhabitants of the little town of Sempach a short way off, so irritated Leopold III. (who then held all the possessions of his house outside Austria) that he collected an army, with the intention of crushing his rebellious town. Lucerne meanwhile had summoned the other members of the League to her aid, and, though Leopold's feint of attacking Zürich caused the troops of the League to march at first in that direction, they discovered their mistake in time to turn back and check his advance on Lucerne. From 1500 to 1600 men of Uri, Schwyz, Unterwalden, and Lucerne opposed the 6000 which made up the Austrian army. The decisive fight took place on the 9th of July 1386, near Sempach, on a bit of sloping meadow-land, cut up by streams and hedges, which forced the Austrian knights to dismount. The great heat of the day, which rendered it impossible to fight in armour, and the furious attacks of the Confederates, finally broke the Austrian line after more than one repulse and turned the day (see WINKELRIED). Leopold, with a large number of his followers, was slain, and the Habsburg power within the borders of the Confederation finally broken. Glarus at once rose in arms against Austria, but it was not till the expiration of the truce made after Sempach that Leopold's brother, Albert of Austria, brought an army against Glarus, and was defeated at Näfels (not far from Glarus) on the 9th of April 1388, by a handful of Glarus and Schwyz men

In 1389 a peace for seven years was made, the Confederates being secured in all their conquests; an attempt made in 1393 by Austria by means of Schöno, the chief magistrate of Zürich and leader of the patrician party, to stir up a fresh attack failed owing to a rising of the burghers, who sympathized with the Confederates, and on the 16th of July 1394 the peace was prolonged for twenty years (and again in 1412 for fifty years), various stipulations being made by which the long struggle of the League against the Habsburgs was finally crowned with success.

Freedom from the Political Claims of the Habsburgs.

By the peace of 1394 Glarus was freed on payment of £200 annually (in 1395 it bought up all the rights of Säckingen); Zug too was released from Austrian rule. Schwyz was given the *advocatia* of the great abbey of Einsiedeln; Lucerne got the Entlebuch (finally in 1405), Sempach and Rothenburg, Bern and Soleure were confirmed in their conquests. Above all, the Confederation as a whole was relieved from the overlordship of the Habsburgs, to whom, however, all their rights and dues as landed proprietors were expressly reserved; Bern, Zürich and Soleure guaranteeing the maintenance of these rights and dues, with power in case of need to call on the other Confederates to support them by arms. Though the house of Habsburg entertained hopes of recovering its former rights, so that technically the treaties of 1389, 1394 and 1412 were but truces, it finally and for ever renounced all its feudal rights and privileges within the Confederation by the "Everlasting Compact" of 1474.

It is probable that Bern did not take any active share in the Sempach War because she was bound by the treaty of peace made with the Austrians in 1368; and Soleure, allied with Bern, was doubtless a party to the treaty of 1394 (though not yet in the League), because of its sufferings in 1382 at the hands of the Kyburg line of the Habsburgs, whose possessions (Thun, Burgdorf, &c.) in 1384 fell into the hands of the two allies.

We may mention here the foray (known as the English or Gugler War) made in 1375 by Enguerrand de Coucy (husband of Isabella, daughter of Edward III. of England) and his freebooters (many of them Englishmen and Welshmen), called "Gugler" from their pointed steel caps, with the object of obtaining possession of certain towns in the Aargau (including Sempach), which he claimed as the dowry of his mother Catherine, daughter of the Leopold who was defeated at Morgarten. He was put to rout in the Entlebuch by the men of Bern, Lucerne, Schwyz and Unterwalden in December 1375. This victory was commemorated with great rejoicings in 1875.

3. The great victory at Sempach not merely vastly increased the fame of the Everlasting League but also enabled it to extend both its influence and its territory. The 15th century is the period when both the League and its several members took the aggressive, and the expansion of their power and lands cannot be better seen than by comparing the state of things at the beginning and at the end of this century. The pastoral highlands of Appenzell (Abbatis Cella) and the town of St Gall had long been trying to throw off the rights exercised over them by the great abbey of St Gall. The Appenzellers, especially, had offered a stubborn resistance, and the abbot's troops had been beaten back by them in 1403 on the heights of Vögelinseck, and again in 1405 in the great fight on the Stoss Pass (which leads up into the highlands), in which the abbot was backed by the duke of Austria. The tales of the heroic defence of Uri Rotach of Appenzell, and of the appearance of a company of Appenzell women disguised as warriors which turned the battle, are told in connexion with this fight, but do not appear till the 17th and 18th centuries, being thus quite unhistorical, so far as our genuine evidence goes. Schwyz had given them some help, and in 1411 Appenzell was placed under the protection of the League (save Bern), with which in the next year the city of St Gall made a similar treaty to last ten years. So too in 1416–1417 several of the "tithings" of the Upper Valais (*i.e.* the upper stretch of the Rhone valley), which in 1388 had beaten the bishop and the nobles in a great fight at Visp, became closely associated with Lucerne, Uri and Unterwalden. It required aid in its final struggle (1418–19) against the great house of Raron, the count-bishop of Sitten (or Sion), and the house of Savoy, which held the Lower Valais—the Forest districts, on the other hand, wishing to secure themselves against Raron and Savoy in their attempt to conquer permanently the Val d'Ossola on the south side of the Simplon Pass. Bern, however, supported its burgher, the lord of Raron, and peace was made in 1420. Such were the first links which bound these lands with the League; but they did not become full members for a long time—Appenzell in 1513, St Gall in 1803, the Valais in 1815.

Struggles in Appenzell, St Gall and the Valais.

Space will not allow us to enumerate all the small conquests made in the first half of the 15th century by every member of the League; suffice it to say that each increased and rounded off its territory, but did not give the conquered lands any political rights, governing them as "subject lands," often very harshly. The same phenomenon of lands which had won their own freedom playing the part of tyrant over other lands which joined them more or less by their voluntary action is seen on a larger scale in the case of the conquest of the Aargau, and in the first attempts to secure a footing south of the Alps.

In 1412 the treaty of 1394 between the League and the Habsburgs had been renewed for fifty years; but when in 1415 Duke Frederick of Austria helped Pope John XXII. to escape from Constance, where the great oecumenical council was then sitting, and the emperor Sigismund placed the duke under the ban of the Empire, summoning all members of the Empire to arm against him, the League hesitated, because of their treaty of 1412, till the emperor declared that all the rights and lands of Austria in the League were forfeited, and that their compact did not release them from their obligations to the Empire. In the name, therefore, of the emperor, and by his special command, the different members of the League overran the extensive Habsburg possessions in the Aargau. The chief share fell to Bern, but certain districts (known as the *Freie Aemter*) were joined together and governed as bailiwicks held in common by all the members of the League (save Uri, busied in the south, and Bern, who had already secured the lion's share of the spoil for herself). This is the first case in which the League as a whole took up the position of rulers over districts which, though guaranteed in the enjoyment of their old rights, were nevertheless politically unfree. As an encouragement and a reward, Sigismund had granted in advance to the League the right of criminal jurisdiction (*haute justice* or *Blutbann*), which points to the fact that they were soon to become independent of the Empire, as they were of Austria.

As the natural policy of Bern was to seek to enlarge its borders at the expense of Austria, and later of Savoy, so we find that Uri, shut off by physical causes from extension in other directions, as steadily turned its eyes towards the south. In 1410 the valley of Urseren was finally joined to Uri; though communications were difficult, and carried on only by means of the "Stiebende Brücke," a wooden bridge suspended by chains over the Reuss, along the side of a great rocky buttress (pierced in 1707 by the tunnel known as the Urnerloch), yet this enlargement of the territory of Uri gave it complete command over the St Gotthard Pass, long commercially important, and now to serve for purposes of war and conquest. Already in 1403 Uri and Obwalden had taken advantage of a quarrel with the duke of Milan as to custom dues at the market of Varese to occupy the long narrow upper Ticino valley on the south of the pass called the Val Leventina; in 1411 the men of the same two lands, exasperated by the insults of the local lords, called on the other members of the League, and all jointly (except Bern) occupied the Val d'Ossola, on the south side of the Simplon Pass. But in 1414 they lost this to Savoy, and, with the object of getting it back, obtained in 1416–1417 the alliance of the men of the Upper Valais, then fighting for freedom, and thus regained (1416) the valley, despite the exertions of the great Milanese general Carmagnola. In 1419 Uri and Obwalden bought from its lord the town and district of Bellinzona. This rapid advance, however, did not approve itself to the duke of Milan, and Carmagnola reoccupied both valleys; the Confederates were not at one with regard to these southern conquests; a small body pressed on in front of the rest, but was cut to pieces at Arbedo near Bellinzona in 1422. A bold attempt in 1425 by a Schwyzer, Peter Rissi by name, to recover the Val d'Ossola caused the Confederates to send a force to rescue these adventurers; but

First Italian Conquests.

the duke of Milan intrigued with the divided Confederates, and finally in 1426, by a payment of a large sum of money and the grant of certain commercial privileges, the Val Leventina, the Val d'Ossola and Bellinzona were formally restored to him. Thus the first attempt of Uri to acquire a footing south of the Alps failed; but a later attempt was successful, leading to the inclusion in the Confederation of what has been called "Italian Switzerland."

The First Civil War.

The original contrasts between the social condition of the different members of the League became more marked when the period of conquest began, and led to quarrels and ill-feeling in the matter of the Aargau and the Italian conquests which a few years later ripened into a civil war, brought about by the dispute as to the succession to the lands of Frederick, count of Toggenburg, the last male representative of his house. Count Frederick's predecessors had greatly extended their domains, so that they took in not only the Toggenburg or upper valley of the Thur, but Uznach, Sargans, the Rhine valley between Feldkirch and Sargans, the Prättigau and the Davos valley. He himself, the last great feudal lord on the left bank of the Rhine, had managed to secure his vast possessions by making treaties with several members of the League, particularly Zürich (1400) and Schwyz (1417)—from 1428 inclining more and more to Schwyz (then ruled by Ital Riding), as he was disgusted with the arrogant behaviour of Stüssi, the burgomaster of Zürich. His death (April 30, 1436) was the signal for the breaking out of strife. The Prättigau and Davos valley formed the League of the Ten Jurisdictions in Raetia (see below), while Frederick's widow sided with Zürich against Schwyz for different portions of the great inheritance which had been promised them. After being twice defeated, Zürich was forced in 1440 to buy peace by certain cessions (the "Höfe") to Schwyz, the general feeling of the Confederates being opposed to Zürich, so that several of them went so far as to send men and arms to Schwyz. Zürich, however, was bitterly disappointed at these defeats, and had recourse to the policy which she had adopted in 1356 and 1393—an alliance with Austria (concluded in 1442), which now held the imperial throne in the person of Frederick III. Though technically within her rights according to the terms on which she had joined the League in 1351, this act of Zürich caused the greatest irritation in the Confederation, and civil war at once broke out, especially when the Habsburg emperor had been solemnly received and acknowledged in Zürich. In 1443 the Zürich troops were completely defeated at St Jakob on the Sihl, close under the walls of the city, Stüssi himself being slain. Next year the city itself was long besieged. Frederick, unable to get help elsewhere, procured from Charles VII. of France the despatch of a body of Armagnac free lances (the Écorcheurs), who came, 30,000 strong, under the dauphin Louis, plundering and harrying the land, till at the very gates of the free imperial city of Basel (which had made a twenty years' alliance with Bern), by the leper house of St Jakob on the Birs (Aug. 26, 1444), the desperate resistance of a small body of Confederates (1200 to 1500), till cut to pieces, checked the advance of the freebooters, who sustained such tremendous losses that, though the victors, they hastily made peace, and returned whence they had come. Several small engagements ensued, Zürich long declining to make peace because the Confederates required, as the result of a solemn arbitration, the abandonment of the Austrian alliance. At length it was concluded in 1450, the Confederates restoring almost all the lands they had won from Zürich. Thus ended the third attempt of Austria to conquer the League by means of Zürich, which used its position as an imperial free city to the harm of the League, and caused the first civil war by which it was distracted.

Constitution of the League, c. 1450.

These fresh proofs of the valour of the Confederates, and of the growing importance of the League, did not fail to produce important results. In 1452 the "Confederates of the Old League of Upper Germany" (as they styled themselves) made their first treaty of alliance with France, a connexion which was destined to exercise so much influence on their history. Round the League there began to gather a new class of allies (known as "Zugewandte Orte," or associated districts), more closely joined to it, or to certain members of it, than by a mere treaty of friendship, yet not being admitted to the rank of a full member of the League. Of these associates three, the abbot (1451) and town of St Gall (1454), and the town of Bienne (Biel), through its alliance (1352) with Bern, were given seats and votes in the Diet, being called *socii*; while others, known as *confoederati*, were not so closely bound to the League, such as the Valais (1416–1417), Schaffhausen (1454), Rottweil (1463), Mühlhausen (1466), (to the class of *confoederati* belonged in later times Neuchâtel 1406–1501), the Three Leagues of Raetia (1497–1498), Geneva (1519–1536), and the bishop of Basel (1579). Appenzell, too, in 1452, rose from the rank of a "protected district" into the class of associates, outside which were certain places "protected" by several members of the League, such as Gersau (1359), the abbey of Engelberg (*c.* 1421), and the town of Rapperswil (1464). The relation of the "associates" to the League may be compared with the ancient practice of "commendation": they were bound to obey orders in declaring war, making alliances, &c.

In 1439 Sigismund succeeded his father Frederick in the Habsburg lands in Alsace, the Thurgau, and Tirol and, being much irritated by the constant encroachments of the Confederates, in particular by the loss of Rapperswil (1458), declared war against them, but fared very badly. In 1460 the Confederates overran the Thurgau and occupied Sargans. Winterthur was only saved by an heroic defence. Hence in 1461 Sigismund had to give up his claims on those lands and renew the peace for fifteen years, while in 1467 he sold Wintherthur to Zürich. Thus the whole line of the Rhine was lost to the Habsburgs, who retained (till 1801) in the territories of the Confederates the Frickthal only. The Thurgovian bailiwicks were governed in common as "subject" lands by all the Confederates except Bern. The touchiness of the now rapidly advancing League was shown by the eagerness with which in 1468 its members took up arms against certain small feudal nobles who were carrying on a harassing guerrilla warfare with their allies Schaffhausen and Mühlhausen. They laid siege to Waldshut, and to buy them off Sigismund in August 1468 engaged to pay 10,000 gulden as damages by the 24th of June 1469; in default of payment the Confederates were to keep for ever the Black Forest, and Waldshut, one of the Black Forest towns on the Rhine. A short time before (1467) the League had made treaties of friendship with Philip the Good, duke of Burgundy, and with the duke of Milan. All was now prepared for the intricate series of intrigues which led up to the Burgundian War—a great epoch in the history of the League, as it created a common national feeling, enormously raised its military reputation, and brought about the close connexion with certain parts of Savoy, which finally (1803–1815) were admitted into the League.

The Burgundian War.

Sigismund did not know where to obtain the sum he had promised to pay. In this strait he turned to Charles the Bold (properly the Rash), duke of Burgundy, who was then beginning his wonderful career, and aiming at restoring the kingdom of Burgundy. For this purpose Charles wished to marry his daughter and heiress to Maximilian, son of the emperor, and first cousin of Sigismund, in order that the emperor might be induced to give him the Burgundian crown. Hence he was ready to meet Sigismund's advances. On the 9th of May 1469 Charles promised to give Sigismund 50,000 florins, receiving as security for repayment Upper Alsace, the Breisgau, the Sundgau, the Black Forest, and the four Black Forest towns on the Rhine (Rheinfelden, Säckingen, Laufenburg and Waldshut), and agreed to give Sigismund aid against the Swiss, if he was attacked by them. It was not unnatural for Sigismund to think of attacking the League, but Charles's engagement to him is quite inconsistent with the friendly agreement made between Burgundy and the League as late as 1467. The emperor then on his side annulled Sigismund's treaty of 1468 with the Swiss, and placed them under the ban of the Empire. Charles committed the mortgaged lands to Peter von Hagenbach, who proceeded to try to establish his master's power there by such harsh measures as to cause the people to rise against him.

The Swiss in these circumstances began to look towards Louis XI. of France, who had confirmed the treaty of friendship made with them by his father in 1452. Sigismund had applied to him early in 1469 to help him in his many troubles, and to give him aid against the Swiss, but Louis had point-blank refused. Anxious to secure their neutrality in case of his war with Charles, he made a treaty with them on the 13th of August 1470 to this effect. All the evidence goes to show that Sigismund was not a tool in the hands of Louis, and that Louis, at least at that time, had no definite intention of involving Charles and the Swiss in a war, but wished only to secure his own flank.

Sigismund in the next few years tried hard to get from Charles the promised aid against the Swiss (the money was paid punctually enough by Charles on his behalf), who put him off with various excuses. Charles on his side, in 1471–1472, tried to make an alliance with the Swiss, his efforts being supported by a party in Bern headed by Adrian von Bubenberg. Probably Charles wished to use both Sigismund and the Swiss to further his own interests, but his shifty policy had the effect of alienating both from him. Sigismund, disgusted with Charles, now inclined towards Louis, whose ally he formally became in the summer of 1473—a change which was the real cause of the emperor's flight from Treves in November 1473, when he had come there expressly to crown Charles. The Confederates on their side were greatly moved by the oppression of their friends and allies in Alsace by Hagenbach, and tried in vain (January 1474) to obtain some redress from his master. Charles's too astute policy had thus lost him both Sigismund and the Swiss. They now looked upon Louis, who, thoroughly aware of Charles's ambition, and fearing that his disappointment at Treves would soon lead to open war, aimed at a master stroke—no less than the reconciliation of Sigismund and the Swiss. This on the face of it seemed impracticable, but common need and Louis's dexterous management brought it to pass, so that on the 30th of March 1474 the Everlasting Compact was signed at Constance, by which Sigismund finally renounced all Austrian claims on the lands of the Confederates, and guaranteed them in quiet enjoyment to them; they, on the other hand, agreed to support him if Charles did not give up the mortgaged lands when the money was paid down. The next day the Swiss joined the league of the Alsatian and Rhine cities, as also did Sigismund. Charles was called on to receive the money contributed by the Alsatian cities, and to restore his lands to Sigismund. He, however, took no steps. Within a week the oppressive bailiff Hagenbach was captured, and a month later (May 9, 1474) he was put to death, Bern alone of the Confederates being represented. On the 9th of October the emperor, acting of course at the instance of Sigismund, ordered them to declare war against Charles, which took place on the 25th of October. Next day Louis formally ratified his alliance with the Confederates, promising money and pensions, the latter to be increased if he did not send men. Throughout these negotiations and later Bern directs Swiss policy, though all the Confederates are not quite agreed. She was specially exposed to attack from Charles and Charles's ally (since 1468) Savoy, and her best chance of extending her territory lay towards the west and south. A forward policy was thus distinctly the best for Bern, and this was the line supported by the French party under Nicholas von Diesbach, Adrian von Bubenberg opposing it, though not with any idea of handing over Bern to Charles. The Forest districts, however, were very suspicious of this movement to the west, by which Bern alone could profit, though the League as a whole might lose; then, too, Uri had in 1440 finally won the Val Leventina, and she and her neighbours favoured a southerly policy—a policy which was crowned with success after the gallant victory won at Giornico in 1478 by a handful of men from Zürich, Lucerne, Uri and Schwyz over 12,000 Milanese troops. Thus Uri first gained a permanent footing south of the Alps, not long before Bern won its first conquests from Savoy.

The war in the west was begun by Bern and her allies (Fribourg, Soleure, &c.) by marauding expeditions across the Jura, in which Héricourt (November 1474) and Blamont (August 1475) were taken, both towns being held of Charles by the "sires" de Neuchâtel, a cadet line of the counts of Montbéliard. It is said that in the former expedition the white cross was borne (for the first time) as the ensign of the Confederates, but not in the other. Meanwhile Yolande, the duchess of Savoy, had, through fear of her brother Louis XI. and hatred of Bern, finally joined Charles and Milan (January 1475), the immediate result of which was the capture, by the Bernese and friends (on the way back from a foray on Pontarlier in the free county of Burgundy or Franche-Comté), of several places in Vaud, notably Grandson and Échallens, both held of Savoy by a member of the house of Chalon, princes of Orange (April 1475), as well as of Orbe and Jougne, held by the same, but under the count of Burgundy. In the summer Bern seized on the Savoyard district of Aigle. Soon after (October–November 1475) the same energetic policy won for her the Savoyard towns of Morat, Avenches, Estavayer and Yverdon; while (September) the Upper Valais, which had conquered all Lower or Savoyard Valais, entered into alliance with Bern for the purpose of opposing Savoy by preventing the arrival of Milanese troops. Alarmed at their success, the emperor and Louis deserted (June–September) the Confederates, who thus, by the influence of Louis and Bernese ambition, saw themselves led on and then abandoned to the wrath of Charles, and very likely to lose their new conquests. They had entered on the war as "helpers" of the emperor, and now became principals in the war against Charles, who raised the siege of Neuss, made an alliance with Edward IV. of England, received the surrender of Lorraine, and hastened across the Jura (February 1476) to the aid of his ally Yolande. On the 21st of February Charles laid siege to the castle of Grandson, and after a week's siege the garrison of Bernese and Fribourgers had to surrender (Oct. 28), while, by way of retaliation for the massacre of the garrison of Estavayer in 1475, of the 412 men two only were spared in order to act as executioners of their comrades. This hideous news met a large body of the Confederates gathered together in great haste to relieve the garrison, and going to their rendezvous at Neuchâtel, where both the count and town had become allies of Bern in 1406. An advance body of Bernese, Fribourgers and Schwyzers, in order to avoid the castle of Vauxmarcus (seized by Charles), on the shore of the Lake of Neuchâtel, and on the direct road from Neuchâtel to Grandson, climbed over a wooded spur to the north, and attacked (March 2) the Burgundian outposts. Charles drew back his force in order to bring down the Swiss to the more level ground where his cavalry could act, but his rear misinterpreted the order, and when the main Swiss force appeared over the spur the Burgundian army was seized with a panic and fled in disorder. The Swiss had gained a glorious victory, and regained their conquest of Grandson, besides capturing very rich spoil in Charles's camp, parts of which are preserved to the present day in various Swiss armouries. Such was the famous battle of Grandson. Charles at once retired to Lausanne, and set about reorganizing his army. He resolved to advance on Bern by way of Morat (or Murten), which was occupied by a Bernese garrison under Adrian von Bubenburg, and laid siege to it on the 9th of June. The Confederates had now put away all jealousy of Bern, and collected a large army. The decisive battle took place on the afternoon of the 22nd of June, after the arrival of the Zürich contingent under Hans Waldmann. English archers were in Charles's army, while with the Swiss was René, the dispossessed duke of Lorraine. After facing each other many hours in the driving rain, a body of Swiss, by outflanking Charles's van, stormed his palisaded camp, and the Burgundians were soon hopelessly beaten, the losses on both sides (a contrast to Grandson) being exceedingly heavy. Vaud was reoccupied by the Swiss (Savoy having overrun it on Charles's advance); but Louis now stepped in and procured the restoration of that region to Savoy, save Grandson, Morat, Orbe and Échallens, which were to be held by the Bernese jointly with the Fribourgers, Aigle by Bern alone —Savoy at the same time renouncing all its claims over Fribourg. Thus French-speaking districts first became permanently connected with the Confederation, hitherto purely German, and the war had been one for the maintenance of recent conquests, rather than purely in defence of Swiss freedom. Charles tried in vain to raise a third army; René recovered Lorraine, and on the 5th of January 1477, under the walls of Nancy, Charles's wide-reaching plans were ended by his defeat and death, many Swiss being with René's troops. The wish of the Bernese to overrun Franche-Comté was opposed by the older members of the Confederation, and finally, in 1479, Louis, by very large payments, secured the abandonment of all claims on that province, which was annexed to the French crown.

Internal Disputes in the League.

These glorious victories really laid the foundation of Swiss nationality; but soon after them the long-standing jealousy between the civic and rural elements in the Confederation nearly broke it up. This had always hindered common action save in the case of certain pressing questions. In 1370, by the "Parsons' ordinance" (Pfaffenbrief), agreed on by all the Confederates except Bern and Glarus, all residents whether clerics or laymen, in the Confederation who were bound by oath to the duke of Austria were to swear faith to the Confederation, and this oath was to rank before any other; no appeal was to lie to any court spiritual or lay (except in matrimonial and purely spiritual questions) outside the limits of the Confederation, and many regulations were laid down as to the suppression of private wars and keeping of the peace on the high roads. Further, in 1393, the "Sempach ordinance" was accepted by all the Confederates and Soleure; this was an attempt to enforce police regulations and to lay down "articles of war" for the organization and discipline of the army of the Confederates, minute regulations being made against plundering—women, monasteries and churches being in particular protected and secured. But save these two documents common action was limited to the meeting of two envoys from each member of the Confederation and one from each of the "socii" in the Diet, the powers of which were greatly limited by the instructions brought by each envoy, thus entailing frequent reference to his government, and included foreign relations, war and peace, and common arrangements as to police, pestilence, customs duties, coinage, &c. The decisions of the majority did not bind the minority save in the case of the affairs of the bailiwicks ruled in common. Thus everything depended on common agreement and good will. But disputes as to the divisions of the lands conquered in the Burgundian War, and the proposal to admit into the League the towns of Fribourg and Soleure, which had rendered such good help in the war, caused the two parties to form separate unions, for by the latter proposal the number of towns would have been made the same as that of the "Länder," which these did not at all approve. Suspended a moment by the campaign in the Val Leventina, these quarrels broke out after the victory of Giornico; and at the Diet of Stans (December 1481), when it seemed probable that the failure of all attempts to come to an understanding would result in the disruption of the League, the mediation of Nicholas von der Flüe (or Bruder Klaus), a holy hermit of Sachseln in Obwalden, though he did not appear at the Diet in person, succeeded in bringing both sides to reason, and the third great ordinance of the League—the "compact of Stans"—was agreed on. By this the promise of mutual aid and assistance was renewed, especially when one member attacked another, and stress was laid on the duty of the several governments to maintain the peace, and not to help the subjects of any other member in case of a rising. The treasure and movables captured in the war were to be equally divided amongst the combatants, but the territories and towns amongst the members of the League. As a practical proof of the reconciliation, on the same day the towns of Fribourg and Soleure were received as full members of the Confederation, united with all the other members, though on less favourable terms than usual, for they were forbidden to make alliances, save with the consent of all or of the greater part of the other members. Both towns had long been allied with Bern, whose influence was greatly increased by their admission. Fribourg, founded in 1178 by Berthold IV. of Zäringen, had on the extinction of that great dynasty (1218) passed successively by inheritance to Kyburg (1218), by purchase to Austria (1277), and by commendation to Savoy (1452); when Savoy gave up its claims in 1477 Fribourg once more became a free imperial city. She had become allied with Bern as early as 1243, but in the 14th and 15th centuries became Romance-speaking, though from 1483 onwards German gained in strength and was the official language till 1798. Soleure (or Solothurn) had been associated with Bern from 1295, but had in vain sought admission into the League in 1411. Both the new members had done much for Bern in the Burgundian War, and it was for their good service that she now procured them this splendid reward, in hopes perhaps of aid on other important and critical occasions.

The compact of Stans strengthened the bonds which joined the members of the Confederation; and the same centralizing tendency is well seen in the attempt (1483–1489) of Hans Waldmann, the burgomaster of Zürich, to assert the rule of his city over the neighbouring country districts, to place all power in the hands of the gilds (whereas by Brun's constitution the patricians had an equal share), to suppress all minor jurisdictions, and to raise a uniform tax. But this idea of concentrating all powers in the hands of the government aroused great resistance, and led to his overthrow and execution. Peter Kistler succeeded (1470) better at Bern in a reform on the same lines, but less sweeping.

Practical Freedom from the Empire.

The early history of each member of the Confederation, and of the Confederation itself, shows that they always professed to belong to the Empire, trying to become immediately dependent on the emperor in order to prevent oppression by middle lords, and to enjoy practical liberty. The Empire itself had now become very much of a shadow; cities and princes were gradually asserting their own independence, sometimes breaking away from it altogether. Now, by the time of the Burgundian War, the Confederation stood in a position analogous to that of a powerful free imperial city. As long as the emperor's nominal rights were not enforced, all went well; but, when Maximilian, in his attempt to reorganize the Empire, erected in 1495 at Worms an imperial chamber which had jurisdiction in all disputes between members of the Empire, the Confederates were very unwilling to obey it—partly because they could maintain peace at home by their own authority, and partly because it interfered with their practical independence. Again, their refusal to join the "Swabian League," formed in 1488 by the lords and cities of South Germany to keep the public peace, gave further offence, as well as their fresh alliances with France. Hence a struggle was inevitable, and the occasion by reason of which it broke out was the seizure by the Tyrolese authorities in 1499 of the Münsterthal, which belonged to the "Gotteshausbund," one of the three leagues which had gradually arisen in Raetia. These were the "Gotteshausbund" in 1367 (taking in all the dependents of the cathedral church at Chur living in the Oberhalbstein and Engadine); the "Ober" or "Grauer Bund" in 1395 and 1424 (taking in the abbey of Disentis and many counts and lords in the Vorder Rhein valley, though its name is not derived, as often stated, from the "grey coats" of the first members, but from "grawen" or "grafen," as so many counts formed part of it); and the "League of the Ten Jurisdictions" (Zehngerichtenbund), which arose in the Prättigau and Davos valley (1436) on the death of Count Frederick of Toggenburg, but which, owing to certain Austrian claims in it, was not quite so free as its neighbours. The first and third of these became allied in 1450, but the formal union of the three dates only from 1524, as documentary proof is wanting of the alleged meeting at Vazerol in 1471, though practically before 1524 they had very much in common. In 1497 the Ober Bund, in 1498 the Gotteshausbund, made a treaty of alliance with the Everlasting League or Swiss Confederation, the Ten Jurisdictions being unable to do more than show sympathy, owing to Austrian claims, which were not bought up till 1649 and 1652. Hence this attack on the Münsterthal was an attack on an "associate" member of the Swiss Confederation, Maximilian being supported by the Swabian League; but its real historical importance is the influence it had on the relations of the Swiss to the Empire. The struggle lasted several months, the chief fight being that in the Calven gorge (above Mals; May 22, 1499), in which Benedict Fontana, a leader of the Gotteshausbund men, performed many heroic deeds before his death. But, both sides being exhausted, peace was made at Basel on the 22nd of September 1499. By this the matters in dispute were referred to arbitration, and the emperor annulled all the decisions of the imperial chamber against the Confederation; but nothing was laid down as to its future relations with the Empire. No further real attempt, however, was made to enforce the rights of the emperor, and the Confederation became a state allied with the Empire, enjoying practical independence, though not formally freed till 1648. Thus, 208 years after the origin of the Confederation in 1291, it had got rid of all Austrian claims (1394 and 1474), as well as all practical subjection to the emperor. But its further advance towards the position of an independent state was long checked by religious divisions within, and by the enormous influence of the French king on its foreign relations.

With the object of strengthening the northern border of the Confederation, two more full members were admitted in 1501—Basel and Schaffhausen—on the same terms as Fribourg and Soleure. The city of Basel had originally been ruled by its bishop, but early in the 14th century it became a free imperial city; before 1501 it had made no permanent alliance with the Confederation, though it had been in continual relations with it. Schaffhausen had grown up round the Benedictine monastery of All Saints, and became in the early 13th century a free imperial city, but was mortgaged to Austria from 1330 to 1415, in which last year the emperor Sigismund declared all Duke Frederick's rights forfeited in consequence of his abetting the flight of Pope John XXII. It bought its freedom in 1418 and became an "associate" of the Confederation in 1454.

The League enlarged to Thirteen Members.

A few years later, in 1513, Appenzell, which in 1411 had become a "protected" district, and in 1452 an "associate" member of the Confederation, was admitted as the thirteenth full member; and this remained the number till the fall of the old Confederation in 1798. Round the three original members had gathered first five others, united with the three, but not necessarily with each other; and then gradually there grew up an outer circle, consisting of five more, allied with all the eight old members, but tied down by certain stringent conditions. Constance, which seemed called by nature to enter the League, kept aloof, owing to a quarrel as to criminal jurisdiction in the Thurgau, pledged to it before the district was conquered by the Confederates.

Conquests in Italy.

In the first years of the 16th century the influence of the Confederates south of the Alps was largely extended. The system of giving pensions, in order to secure the right of enlisting men within the Confederation, and of capitulations, by which the different members supplied troops, was originated by Louis XI. in 1474, and later followed by many other princes. Though a tribute to Swiss valour and courage, this practice had very evil results, of which the first-fruits were seen in the Milanese troubles (1500–1516), of which the following is a summary. Both Charles VIII. (1484) and Louis XII. (1499 for ten years) renewed Louis XI.'s treaty. The French attempts to gain Milan were largely carried on by the help of Swiss mercenaries, some of whom were on the opposite side; and, as brotherly feeling was still too strong to make it possible for them to fight against one another, Lodovico Sforza's Swiss troops shamefully betrayed him to the French at Novara (1500). In 1500, too, the three Forest districts occupied Bellinzona (with the Val Blenio) at the request of its inhabitants, and in 1503 Louis XII. was forced to cede it to them. He, however, often held back the pay of his Swiss troops, and treated them as mere hirelings, so that when the ten years' treaty came to an end Matthew Schinner, bishop of Sitten (or Sion), induced them to join (1510) the pope, Julius II., then engaged in forming the Holy League to expel the French from Italy. But when, after the battle of Ravenna, Louis XII. became all-powerful in Lombardy, 20,000 Swiss poured down into the Milanese and occupied it, Felix Schmid, the burgomaster of Zürich, naming Maximilian (Lodovico's son) duke of Milan, in return for which he ceded to the Confederates Locarno, Val Maggia, Mendrisio and Lugano (1512), while the Raetian Leagues seized Chiavenna, Bormio and the Valtellina. (The former districts, with Bellinzona, the Val Blenio and the Val Leventina, were in 1803 made into the canton of Ticino, the latter were held by Raetia till 1797.) In 1513 the Swiss completely defeated the French at Novara, and in 1515 Pace was sent by Henry VIII. of England to give pensions and get soldiers. Francis I. at once on his accession (1515) began to prepare to win back the Milanese, and, successfully evading the Swiss awaiting his descent from the Alps, beat them in a pitched battle at Marignano near Milan (Sept. 13, 1515), which broke the Swiss power in north Italy, so that in 1516 a peace was made with France—the Valais, the Three Raetian Leagues and both the abbot and town of St Gall being included on the side of the Confederates. Provision was made for the neutrality of either party in case the other became involved in war, and large pensions were promised. This treaty was extended by another in 1521 (to which Zürich, then under Zwingli's influence, would not agree, holding aloof from the French alliance till 1614), by which the French king might, with the consent of the Confederation, enlist any number of men between 6000 and 16,000, paying them fit wages, and the pensions were raised to 3000 francs annually to each member of the Confederation. These two treaties were the starting-point of later French interference with Swiss affairs.

The Reformation.

4. In 1499 the Swiss had practically renounced their allegiance to the emperor, the temporal chief of the world according to medieval theory; and in the 16th century a great number of them did the same by the world's spiritual chief, the pope. The scene of the revolt was Zürich, and the leader Ulrich Zwingli (who settled in Zürich at the very end of 1518). But we cannot understand Zwingli's career unless we remember that he was almost more a political reformer than a religious one. In his former character his policy was threefold. He bitterly opposed the French alliance and the pension and mercenary system, for he had seen its evils with his own eyes when serving as chaplain with the troops in the Milanese in 1512 and 1515. Hence in 1521 his influence kept Zürich back from joining in the treaty with Francis I. Then, too, at the time of the Peasant Revolt (1525), he did what he could to lighten the harsh rule of the city over the neighbouring rural districts, and succeeded in getting serfage abolished. Again he had it greatly at heart to secure for Zürich and Bern the chief power in the Confederation, because of their importance and size; he wished to give them extra votes in the Diet, and would have given them two-thirds of the "common bailiwicks" when these were divided. In his character as a religious reformer we must remember that he was a humanist, and deeply read in classical literature, which accounts for his turning the canonries of the Grossmünster into professorships, reviving the old school of the Carolinum, and relying on the arm of the state to carry out religious changes (see ZWINGLI). After succeeding at two public disputations (both held in 1523) his views rapidly gained ground at Zürich, which long, however, stood quite alone, the other Confederates issuing an appeal to await the decision of the asked-for general council, and proposing to carry out by the arm of the state certain small reforms, while clinging to the old doctrines. Zwingli had to put down the extreme wing of the Reformers—the Anabaptists—by force (1525–1526). Quarrels soon arose as to allowing the new views in the "common bailiwicks." The disputation at Baden (1526) was in favour of the maintainers of the old faith; but that at Bern (1528) resulted in securing for the new views the support of that great town, and so matters began to take another aspect. In 1528 Bern joined the union formed in December 1527 in favour of religious freedom by Zürich and Constance (*Christliches Burgrecht*), and her example was followed by Schaffhausen, St Gall, Basel, Bienne and Mühlhausen (1528–1529). This attempt virtually to break up the League was met in February 1529 by the offensive and defensive alliance made with King Ferdinand of Hungary (brother of the emperor) by the three Forest districts, with Lucerne and Zug, followed (April 1529) by the "Christliche Vereinigung," or union between these five members of the

League. Zürich was greatly moved by this, and, as Zwingli held that for the honour of God war was as necessary as iconoclasm, hostilities seemed imminent; but Bern held back; and the first peace of Kappel was concluded (June 1529), by which the Hungarian alliance was annulled and the principle of "religious parity" (or freedom) was admitted in the case of each member of the League, while in the "common bailiwicks" the majority in each parish was to decide the religion of that parish. This was at once a victory and a check for Zwingli. He tried to make an alliance with the Protestants in Germany, but failed at the meeting at Marburg (October 1529) to come to an agreement with Luther on the subject of the Eucharist, and the division between the Swiss and the German Reformations was stereotyped. Zwingli now developed his views as to the greater weight which Zürich and Bern ought to have in the League. Quarrels, too, went on in the "common bailiwicks," for the members of the League who clung to the old faith had a majority of votes in matters relating to these districts. Zürich tried to cut off supplies of food from reaching the Romanist members (contrary to the wishes of Zwingli), and, on the death of the abbot of St Gall, disregarding the rights of Lucerne, Schwyz and Glarus, who shared with her since 1451 the office of protectors of the abbey, suppressed the monastery, giving the rule of the land and the people to her own officers. Bern in vain tried to moderate this aggressive policy, and the Romanist members of the League indignantly advanced from Zug towards Zürich. Near Kappel, on the 11th of October 1531, the Zürich vanguard under Göldli was (perhaps owing to his treachery) surprised, and despite reinforcements the men of Zürich were beaten, among the slain being Zwingli himself. Another defeat completed the discomfiture of Zürich, and by the second peace of Kappel (November 1531) the principle of "parity" was recognized, not merely in the case of each member of the League and of the "common bailiwicks," but in the latter Romanist minorities in every parish were to have a right to celebrate their own worship. Thus everywhere the rights of a minority were protected from the encroachments of the majority. The "Christliches Burgrecht" was abolished, and Zürich was condemned to pay heavy damages. Bullinger succeeded Zwingli, but this treaty meant that neither side could now try to convert the other wholesale. The League was permanently split into two religious camps: the Romanists, who met at Lucerne, numbered, besides the five already mentioned, Fribourg, Soleure, Appenzell (Inner Rhoden) and the abbot of St Gall (with the Valais and the bishop of Basel), thus commanding sixteen votes (out of twenty-nine) in the Diet; the Evangelicals were Zürich, Bern, Schaffhausen, Appenzell (Ausser Rhoden), Glarus and the towns of St Gall, Basel and Bienne (with Graubünden), who met at Aarau.

Bern had her eyes always fixed upon the Savoyard lands to the south-west, in which she had got a footing in 1475, and now made zeal for religious reforms the excuse for resuming her advance policy. In 1526 Guillaume Farel, a preacher from Dauphiné, had been sent to reform Aigle, Morat and Neuchâtel. In 1532 he came to Geneva, an ancient city of which the rule had long been disputed by the prince-bishop, the burgesses and the house of Savoy, the latter holding the neighbouring districts. She had become in 1519 the ally of Fribourg, in 1526 that of Bern also; and in 1530, by their influence, a peace was made between the contending parties. The religious changes introduced by Farel greatly displeased Fribourg, which abandoned the alliance (1534), and in 1535 the Reformation was firmly planted in the city. The duke of Savoy, however, took up arms against Bern (1536), who overran Gex, Vaud and the independent bishopric of Lausanne, as well as the Chablais to the south of the lake. Geneva was only saved by the unwillingness of the citizens. Bern thus ruled north and south of the lake, and carried matters with a high hand. Shortly after this John Calvin, a refugee from Picardy, was, when passing through Geneva, detained by Farel to aid him, and, after an exile from 1538–1541, owing to opposition of the papal party and of the burghers, who objected to Bernese rule, he was recalled (1541) and set up his wonderful theocratic government in the city, in 1553 burning Servetus, the Unitarian (see CALVIN and SERVETUS), and in 1555 expelling many who upheld municipal liberty, replacing them by French, English, Italians and Spaniards as new burghers, whose names are still frequent in Geneva (*e.g.* Candolle, Mallet, Diodati). His theological views led to disputes with the Zürich Reformers, which were partly settled by the *Consensus Tigurinus* of 1549, and more completely by the *Helvetic Confession* of 1562–1566, which formed the basis of union between the two parties.

Conquest of Vaud by Bern.

By the time of Calvin's death (1564) the old faith had begun to take the offensive; the reforms made by the Council of Trent urged on the Romanists to make an attempt to recover lost ground. Emmanuel Philibert, duke of Savoy, the hero of St Quentin (1557), and one of the greatest generals of the day, with the support of the Romanist members of the League, demanded the restoration of the districts seized by Bern in 1536, and on the 30th of October 1564 the Treaty of Lausanne confirmed the decision of the other Confederates sitting as arbitrators (according to the old constitutional custom). By this treaty Gex, the Genevois and the Chablais were to be given back, while Lausanne, Vevey, Chillon, Villeneuve, Nyon, Avenches and Yverdon were to be kept by Bern, who engaged to maintain the old rights and liberties of Vaud. Thus Bern lost the lands south of the lake, in which St Francis of Sales, the exiled prince-bishop of Geneva (1602–1622), at once proceeded to carry out the restoration of the old faith. In 1555 Bern and Fribourg, as creditors of the debt-laden count, divided the county of Gruyère, thus getting French-speaking subjects. In 1558 Geneva renewed her alliance with Bern, and in 1584 she made one with Zürich. The duke of Savoy made several vain attempts to get hold of Geneva, the last (in 1602) being known as the "escalade."

The Counter-Reformation.

The decrees of the Council of Trent had been accepted fully by the Romanist members of the League, so far as relates to dogma, but not as regards discipline or the relations of church and state, the sovereign rights and jurisdiction of each state being always carefully reserved. The counter-Reformation, however, or reaction in favour of the old faith, was making rapid progress in the Confederation, mainly through the indefatigable exertions of Charles Borromeo, from 1560 to 1584 archbishop of Milan (in which diocese the Italian bailiwicks were included), and nephew of Pius IV., supported at Lucerne by Ludwig Pfyffer, who, having been (1562–1570) the chief of the Swiss mercenaries in the French wars of religion, did so much till his death (1594) to further the religious reaction at home that he was popularly known as the "Swiss king." In 1574 the Jesuits, the great order of the reaction, were established at Lucerne; in 1579 a papal nuncio came to Lucerne; Charles Borromeo founded the "Collegium Helveticum" at Milan for the education of forty-two young Swiss, and the Catholic members of the League made an alliance with the bishop of Basel; in 1581 the Capuchins were introduced to influence the more ignorant classes. Most important of all was the Golden or Borromean League, concluded (Oct. 5, 1586) between the seven Romanist members of the Confederation (Uri, Schwyz, Unterwalden, Lucerne, Zug, Fribourg and Soleure) for the maintenance of the true faith in their territories, each engaging to punish backsliding members and to help each other if attacked by external enemies, notwithstanding any other leagues, old or new. This league marks the final breaking up of the Confederation into two great parties, which greatly hindered its progress. The Romanist members had a majority in the Diet, and were therefore able to refuse admittance to Geneva, Strassburg and Mühlhausen. Another result of these religious differences was the breaking up of Appenzell into two parts (1597), each sending one representative to the Diet—"Inner Rhoden" remaining Romanist, "Ausser Rhoden" adopting the new views. We may compare with this the action of Zürich in 1555, when she received the Protestant exiles (bringing with them the silk-weaving industry) from Locarno and the Italian bailiwicks into her burghership, and Italian names are found there to this day (*e.g.* Orelli, Muralt).

In the Thirty Years' War the Confederation remained neutral, being bound both to Austria (1474) and to France (1516), and neither religious party wishing to give the other an excuse for calling in foreign armies. But the troubles in Raetia threatened entanglements. Austria wished to secure the Münsterthal (belonging to the League of the Ten Jurisdictions), and Spain wanted the command of the passes leading from the Valtellina (conquered by the leagues of Raetia in 1512), the object being to connect the Habsburg lands of Tirol and Milan. In the Valtellina the rule of the Three Raetian Leagues was very harsh, and Spanish intrigues easily brought about the massacre of 1620, by which the valley was won, the Romanist members of the Confederation stopping the troops of Zürich and Bern. In 1622 the Austrians conquered the Prättigau, over which they still had certain feudal rights. French troops regained the Valtellina in 1624, but it was occupied once more in 1629 by the imperial troops, and it was not till 1635 that the French, under Rohan, finally succeeded in holding it. The French, however, wished to keep it permanently; hence new troubles arose, and in 1637 the natives, under George Jenatsch, with Spanish aid drove them out, the Spaniards themselves being forced to resign it in 1639. It was only in 1649 and 1652 that the Austrian rights in the Prättigau were finally bought up by the League of the Ten Jurisdictions, which thus gained its freedom.

In consequence of Ferdinand II.'s edict of restitution (1629), by which the *status quo* of 1552 was re-established—the high-water mark of the counter-Reformation—the abbot of St Gall tried to make some religious changes in his territories, but the protest of Zürich led to the Baden compromise of 1632, by which, in the case of disputes on religious matters arising in the "common bailiwicks," the decision was to be, not by a majority of the cantons, but by means of friendly discussion—a logical application of the doctrine of religious parity—or by arbitration.

But by far the most important event in Swiss history in this age is the formal freeing of the Confederation from the empire.

Formal Freedom from the Empire.

Basel had been admitted a member of the League in 1501, two years after the Confederation had been practically freed from the jurisdiction of the imperial chamber, though the city was included in the new division of the empire into "circles" (1521), which did not take in the older members of the Confederation. Basel, however, refused to admit this jurisdiction; the question was taken up by France and Sweden at the congress of Münster, and formed the subject of a special clause in both the treaties of Westphalia, by which the city of Basel and the other "Helvetiorum cantones" were declared to be "in the possession, or almost in the possession, of entire liberty and exemption from the empire, and *nullatenus* subject to the imperial tribunals." This was intended to mean formal exemption from all obligations to the empire (with which the Confederation was connected hereafter simply as a friend), and to be a definitive settlement of the question. Thus by the events of 1499 and 1648 the Confederation had become an independent European state, which, by the treaty of 1516, stood as regards France in a relation of neutrality.

In 1668, in consequence of Louis XIV.'s temporary occupation of the Franche Comté, an old scheme for settling the number of men to be sent by each member of the Confederation to the joint army, and the appointment of a council of war in war time, that is, an attempt to create a common military organization, was accepted by the Diet, which was to send two deputies to the council, armed with full political powers. This agreement, known as the *Defensionale*, is the only instance of joint and unanimous action in this miserable period of Swiss history, when religious divisions crippled the energy of the Confederation.

Throughout the 17th and 18th centuries the Confederation was practically a dependency of France. In 1614 Zürich for

French Influence, Religious Divisions, and Rise of an Aristocracy.

the first time joined in the treaty, which was renewed in 1663 with special provisions as regards the Protestant Swiss mercenaries in the king's pay and a promise of French neutrality in case of civil war in the League. The Swiss had to stand by while Louis XIV. won Alsace (1648), Franche Comté (1678) and Strassburg (1681). But, as Louis inclined more and more to an anti-Protestant policy, the Protestant members of the League favoured the Dutch military service; and it was through their influence that in 1707 the "states" of the principality of Neuchâtel, on the extinction of the Longueville line of these princes, decided in favour of the king of Prussia (representing the overlords—the house of Chalon-Orange) as against the various French pretenders claiming from the Longueville dynasty by descent or by will. In 1715 the Romanist members of the League, in hopes of retrieving their defeat of 1712 (see below), agreed, while renewing the treaty and capitulations, to put France in the position of the guarantor of their freedom, with rights of interfering in case of attack from within or from without, whether by counsel or arms, while she promised to procure restitution of the lands lost by them in 1712. This last clause was simply the surrender of Swiss independence, and was strongly objected to by the Protestant members of the Confederation, so that in 1777 it was dropped, when all the Confederates made a fresh defensive alliance, wherein their sovereignty and independence were expressly set forth. Thus France had succeeded to the position of the empire with regard to the Confederation, save that her claims were practically asserted and voluntarily admitted.

Between 1648 and 1798 the Confederation was distracted by religious divisions and feelings ran very high. A scheme to set up a central administration fell through in 1655, through jealousy of Bern and Zürich, the proposers. In 1656 a question as to certain religious refugees, who were driven from Schwyz and took refuge at Zürich, brought about the first Villemergen War, in which the Romanists were successful, and procured a clause in the treaty asserting very strongly the absolute sovereignty, in religious as well as in political matters, of each member of the League within its own territories, while in the "common bailiwicks" the Baden arrangement (1632) was to prevail. Later, the attempt of the abbot of St Gall to enforce his rights in the Toggenburg swelled into the second Villemergen War (1712), which turned out very ill for the defeated Romanists. Zürich and Bern were henceforth to hold in severalty Baden, Rapperswil, and part of the "common bailiwicks" of the Aargau, both towns being given a share in the government of the rest, and Bern in that of Thurgau and Rheinthal, from which, as well as from that part of Aargau, she had been carefully excluded in 1415 and 1460. The only thing that prospered was the principle of "religious parity," which was established completely, as regards *both* religions, within each parish in the "common bailiwick."

The Diet had few powers; the Romanists had the majority there; the sovereign rights of each member of the League and the limited mandate of the envoys effectually checked all progress. Zürich, as the leader of the League, managed matters when the Diet was not sitting, but could not enforce her orders. The Confederation was little more than a collection of separate atoms, and it is really marvellous that it did not break up through its own weakness.

In these same two centuries, the chief feature in domestic Swiss politics is the growth of an aristocracy: the power of voting and the power of ruling are placed in the hands of a small class. This is chiefly seen in Bern, Lucerne, Fribourg and Soleure, where there were not the primitive democracies of the Forest districts nor the government by gilds as at Zürich, Basel and Schaffhausen. It was effected by refusing to admit any new burghers, a practice which dates from the middle of the 16th century, and is connected (like the similar movement in the smaller local units of the "communes" in the rural districts) with the question of poor relief after the suppression of the monasteries. Outsiders (Hintersasse or Niedergelassene) had no political rights, however long they might have resided, while the privileges of burghership were strictly hereditary. Further, within the burghers, a small class succeeded in securing the monopoly of all public offices, which was kept up by the practice of co-opting, and was known as the "patriciate." So in Bern, out of 360 burgher families 69 only towards the close of the 18th century formed the ruling oligarchy—and, though to foreigners the government seemed admirably managed, yet the last thing that could be said of it was that it was democratic. In 1749 Samuel Henzi (disgusted at being refused the post of town librarian) made a fruitless attempt to overthrow this oligarchy, like the lawyer, Pierre Fatio at Geneva in 1707. The harsh character of Bernese rule (and the same holds good with reference to Uri and the Val Leventina) was shown in the great strictness with which its subject land Vaud was kept in hand: it was ruled as a conquered land by a benevolent despot, and we can feel no surprise that Major J. D. A. Davel in 1723 tried to free his native land, or that it was in Vaud that the principles of the French Revolution were most eagerly welcomed. Another result of this aristocratic tendency was the way in which the cities despised the neighbouring country districts, and managed gradually to deprive them of their equal political rights and to levy heavy taxes upon them. These and other grievances (the fall in the price of food after the close of the Thirty Years' War, the lowering of the value of the coin, &c.), combined with the presence of many soldiers discharged after the great war, led to the great Peasant Revolt (1653) in the territories of Bern, Soleure, Lucerne and Basel, interesting historically as being the first popular rising since the old days of the 13th and 14th centuries, and because reminiscences of legends connected with those times led to the appearance of the "three Tells," who greatly stirred up the people. The rising was put down at the cost of much bloodshed, but the demands of the peasants were not granted. Yet during this period of political powerlessness a Swiss literature first arises: Conrad Gesner and Giles Tschudi in the 16th century are succeeded by J. J. Scheuchzer, A. von Haller, J. C. Lavater, J. J. Bodmer, H. B. de Saussure, J. J. Rousseau, J. von Müller; the taste for Swiss travel is stimulated by the publication (1793) of the first real Swiss guide-book by J. G. Ebel (*q.v.*), based on the old *Deliciae*; industry throve greatly. The residence of such brilliant foreign writers as Gibbon and Voltaire within or close to the territories of the Confederation helped on this remarkable intellectual revival. Political aspirations were not, however, wholly crushed, and found their centre in the Helvetic Society, founded in 1762 by F. U. Balthasar and others.

Effects of the French Revolution on the Confederation.

The Confederation and France had been closely connected for so long that the outbreak of the French Revolution could not fail to affect the Swiss. The Helvetian Club, founded at Paris in 1790 by several exiled Vaudois and Fribourgers, was the centre from which the new ideas were spread in the western part of the Confederation, and risings directed or stirred up. In 1790 the Lower Valais rose against the oppressive rule of the upper districts; in 1791 Porrentruy defied the prince-bishop of Basel, despite the imperial troops he summoned, and proclaimed (November 1792) the "Rauracian republic," which three months later (1793) became the French department of the Mont Terrible; Geneva was only saved (1792) from France by a force sent from Zürich and Bern; while the massacre of the Swiss guard at the Tuileries on the 10th of August 1792 aroused intense indignation. The rulers, however, unable to enter into the new ideas, contented themselves with suppressing them by force, *e.g.* Zürich in the case of Stäfa (1795). St Gall managed to free itself from its prince-abbot (1795–1797), but the Leagues of Raetia so oppressed their subjects in the Valtellina that in 1797 Bonaparte (after conquering the Milanese from the Austrians) joined them to the Cisalpine republic. The Diet was distracted by party struggles and the fall of the old Confederation was not far distant. The rumours of the vast treasures stored up at Bern, and the desire of securing a bulwark against Austrian attack, specially turned the attention of the directory towards the Confederation; and this was utilized by the heads of the Reform party in the Confederation—Peter Ochs (1752–1821), the burgomaster of Basel, and Frédéric César Laharpe (1754–1838; tutor, 1783–1794, to the later tsar Alexander I.), who had left his home in Vaud through disgust at Bernese oppression, both now wishing for aid from outside in order to free their land from the rule of the oligarchy. Hence, when Laharpe, at the head of some twenty exiles from Vaud and Fribourg, called (Dec. 9, 1797) on the Directory to protect the liberties of Vaud, which, so he said (by a bit of purely apocryphal history), France by the treaty of 1565 was bound to guarantee, his appeal found a ready answer. In February 1798 French troops occupied Mühlhausen and Bienne (Biel), as well as those parts of the lands of the prince-bishop of Basel (St Imier and the Münsterthal) as regards which he had been since 1579 the ally of the Catholic members of the Confederation. Another army entered Vaud (February 1798), when the "Lemanic republic" was proclaimed, and the Diet broke up in dismay without taking any steps to avert the coming storm. Brune and his army occupied Fribourg and Soleure, and, after fierce fighting at Neuenegg, entered (March 5) Bern, deserted by her allies and distracted by quarrels within. With Bern, the stronghold of the aristocratic party, fell the old Confederation. The revolution triumphed throughout the country. Brune (March 16–19) put forth a wonderful scheme by which the Confederation with its "associates" and "subjects" was to be split into three republics—the Tellgau (*i.e.* the Forest districts), the Rhodanic (*i.e.* Vaud, the Valais, the Bernese Oberland and the Italian bailiwicks), and the Helvetic (*i.e.* the northern and eastern portions); but the directory disapproved of this (March 23), and on the 29th of March the "Helvetic republic, one and indivisible," was proclaimed. This was accepted by ten cantons only as well as (April 12) the constitution drafted by Ochs. By the new scheme the territories of the Everlasting League were split up into twenty-three (later nineteen, Raetia only coming in in 1799) administrative districts, called "cantons," a name now officially used in Switzerland for the first time, though it may be found employed by foreigners in the French treaty of 1452, in Commynes and Machiavelli, and in the treaties of Westphalia (1648). A central government was set up, with its seat at Lucerne, comprising a senate and a great council, together forming the legislature, and named by electors chosen by the people in the proportion of 1 to every 100 citizens, with an executive of five directors chosen by the legislature, and having four ministers as subordinates or "chief secretaries." A supreme court of justice was set up; a status of Swiss citizenship was recognized; and absolute freedom to settle in any canton was given, the political "communes" being now composed of all residents, and not merely of the burghers. For the first time an attempt was made to organize the Confederation as a single state, but the change was too sweeping to last, for it largely ignored the local patriotism which had done so much to create the Confederation, though more recently it had made it politically powerless. The three Forest districts rose in rebellion against the invaders and the new constitutions which destroyed their ancient prerogatives; but the valiant resistance of the Schwyzers, under Alois Reding, on the heights of Morgarten (April and May), and that of the Unterwaldners (August and September), were put down by French armies. The proceedings of the French, however, soon turned into disgust and hatred the joyful feelings with which they had been hailed as liberators. Geneva was annexed to France (April 1798); Gersau, after an independent existence of over 400 years, was made a mere district of Schwyz; immense fines were levied and the treasury at Bern pillaged; the land was treated as if it had been conquered. The new republic was compelled to make a very close offensive and defensive alliance with France, and its directors were practically nominated from Paris. In June–October 1799 Zürich, the Forest cantons and Raetia became the scene of the struggles of the Austrians (welcomed with joy) against the French and Russians. The manner, too, in which the reforms were carried out alienated many, and, soon after the directory gave way to the consulate in Paris (18 Brumaire or Nov. 10, 1799), the Helvetic directory (January 1800) was replaced by an executive committee.

The Helvetic Republic.

The scheme of the Helvetic republic had gone too far in the direction of centralization; but it was not easy to find the happy mean, and violent discussions went on between the "Unitary" (headed by Ochs and Laharpe) and "Federalist" parties. Many drafts were put forward and one actually submitted to but rejected by a popular vote (June 1802). In July 1802 the French troops were withdrawn from Switzerland by Bonaparte, ostensibly to comply with the treaty of Amiens, really to show the Swiss that their best hopes lay in appealing to him. The Helvetic government was gradually driven back by armed force, and the Federalists seemed getting the best of it, when (Oct. 4) Bonaparte offered himself as mediator, and summoned ten of the chief Swiss statesmen to Paris to discuss matters with him (the "Consulta"—December 1802). He had long taken a very special interest in Swiss matters, and in 1802 had given to the Helvetic republic the Frickthal (ceded to France in 1801 by Austria), the last Austrian possession within the borders of the Confederation. On the other hand, he had made (August 1802) the Valais into an independent republic. In the discussions he pointed out that Swiss needs required a federal constitution and a neutral position guaranteed by France. Finally (Feb. 19, 1803) he laid before the Consulta the Act of Mediation which he had elaborated and which they had perforce to accept—a document which formed a new departure in Swiss history, and the influence of which is visible in the present constitution.

The Act of Mediation.

Throughout, "Switzerland" is used for the first time as the official name of the Confederation. The thirteen members of the old Confederation before 1798 are set up again, and to them are added six new cantons—two (St Gall and Graubünden or Grisons) having been formerly "associates," and the four others being made up of the subject lands conquered at different times—Aargau (1415), Thurgau (1460), Ticino or Tessin (1440, 1500, 1512), and Vaud (1536). In the Diet, six cantons which had a population of more than 100,000 (viz. Bern, Zürich, Vaud, St Gall, Graubünden and Aargau) were given two votes, the others having but one apiece, and the deputies were to vote freely within limits, though not against their instructions. Meetings of the Diet were to be held alternately at Fribourg, Bern, Soleure, Basel, Zürich and Lucerne—the chief magistrate of each of these cantons being named for that year the "landamman of Switzerland." The "landsgemeinden," or popular assemblies, were restored in the democratic cantons, the cantonal governments in other cases being in the hands of a "great council" (legislative) and the "small council" (executive)—a property qualification being required both for voters and candidates. No canton was to form any political alliances abroad or at home. The "communes" were given larger political rights, the burghers who owned and used the common lands became more and more private associations. There was no Swiss burghership, as in 1798, but perfect liberty of settlement in any canton. There were to be no privileged classes or subject lands. A very close alliance with France (on the basis of that of 1516) was concluded (Sept. 27, 1803). The whole constitution and organization were far better suited for the Swiss than the more symmetrical system of the Helvetic republic; but, as it was guaranteed by Bonaparte, and his influence was predominant, the whole fabric was closely bound up with him, and fell with him. Excellent in itself, the constitution set forth in the Act of Mediation failed by reason of its setting.

For ten years Switzerland enjoyed peace and prosperity under the new constitution. Pestalozzi and Fellenberg worked out their educational theories; K. Escher of Zürich embanked the Linth, and his family was thence called "von der Linth"; the central government prepared many schemes for the common welfare. On the other hand, the mediator (who became emperor in 1804) lavishly expended his Swiss troops, the number of which could only be kept up by a regular blood tax, while the "Berlin decrees" raised the price of many articles. In 1806 the principality of Neuchâtel was given to Marshal Berthier; Tessin was occupied by French troops from 1810 to 1813, and in 1810 the Valais was made into the department of the Simplon, so as to secure that pass. At home, the liberty of moving from one canton to another (though given by the constitution) was, by the Diet in 1805, restricted by requiring ten years' residence, and then not granting political rights in the canton or a right of profiting by the communal property. As soon as Napoleon's power began to wane (1812–1813), the position of Switzerland became endangered. Despite the personal wishes of the tsar (a pupil of Laharpe's), the Austrians, supported by the reactionary party in Switzerland, and without any real resistance on the part of the Diet, as well as the Russians troops, crossed the frontier on the 21st of December 1813, and on the 29th of December the Diet was induced to declare the abolition of the 1803 constitution, guaranteed, like Swiss neutrality, by Napoleon. Bern headed the party which wished to restore the old state of things, but Zürich and the majority stood out for the nineteen cantons. The powers exercised great pressure to bring about a meeting of deputies from all the nineteen cantons at Zürich (April 6, 1814, "the long Diet"); party strife was very bitter, but on the 12th of September it decided that the Valais, Neuchâtel and Geneva should be raised from the rank of "associates" to that of full members of the Confederation (thus making up the familiar twenty-two). As compensation the congress of Vienna (March 20, 1815) gave Bern the town of Bienne (Biel), and all (save a small part which went to Basel) of the territories of the prince-bishop of Basel ("the Bernese Jura"); but the Valtellina was granted to Austria, and Mühlhausen was not freed from France.

The Pact of 1815.

On the 7th of August 1815 the new constitution was sworn to by all the cantons save Nidwalden, the consent of which was only obtained (Aug. 30) by armed force, a delay for which she paid by seeing Engelberg and the valley above (acquired by Nidwalden in 1798) given to Obwalden. By the new constitution the sovereign rights of each canton were fully recognized, and a return made to the lines of the old constitution, though there were to be no subject lands, and political rights were not to be the exclusive privilege of any class of citizens. Each canton had one vote in the Diet, where an absolute majority was to decide all matters save foreign affairs, when a majority of three-fourths was required. The management of current business, &c., shifted every two years between the governments of Zürich, Bern and Lucerne (the three "Vororte"). The monasteries were guaranteed in their rights and privileges; and no canton was to make any alliance contrary to the rights of the Confederation or of any other canton. Provision was made for a Federal army. Finally, the Congress, on the 20th of November 1815, placed Switzerland and parts of North Savoy (Chablais, Faucigny and part of the Genevois) under the guarantee of the Great Powers, who engaged to maintain their neutrality, thus freeing Switzerland from her 300 years' subservience to France, and compensating in some degree for the reactionary nature of the new Swiss constitution when compared with that of 1803.

Attempts at Reform.

5. The cities at once secured for themselves in the cantonal great councils an overwhelming representation over the neighbouring country districts, and the agreement of 1805 as to migration from one canton to another was renewed (1819) by twelve cantons. For some time there was little talk of reforms, but in 1819 the Helvetic Society definitely became a political society, and the foundation in 1824 of the Marksmen's Association enabled men from all cantons to meet together. A few cantons (notably Tessin) were beginning to make reforms, when the influence of the July revolution (1830) in Paris and the sweeping changes in Zürich led the Diet to declare (Dec. 27) that it would not interfere with any reforms of cantonal constitutions provided they were in agreement with the pact of 1815. Hence for the next few years great activity in this direction was displayed, and most of the cantons reformed themselves, save the most conservative (*e.g.* Uri, Glarus) and the advanced who needed no changes (*e.g.* Geneva, Graubünden). Provision was always made for revising these constitutions at fixed intervals, for the changes were not felt to be final, and seven cantons—Zürich, Bern, Lucerne, Soleure, St Gall, Aargau and Thurgau—joined together to guarantee their new free constitutions (Siebener Concordat of March 17, 1832). Soon after, the

question of revising the Federal pact was brought forward by a large majority of cantons in the Diet (July 17), whereon, by the league of Sarnen (Nov. 14), the three Forest cantons, with Neuchâtel, the city of Basel, and the Valais, agreed to maintain the pact of 1815 and to protest against the separation of Basel in two halves (for in the reform struggle Schwyz and Basel had been split up, though the split was permanent only in the latter case). A draft constitution providing for a Federal administration distinct from the cantons could not secure a majority in its favour; a reaction against reform set in, and the Diet was forced to sanction (1833) the division of Basel into the "city" and "country" divisions (each with half a vote in the Diet), though fortunately in Schwyz the quarrel was healed. Religious quarrels further stirred up strife in connexion with Aargau, which was a canton where religious parity prevailed, later in others. In Zürich the extreme pretensions of the Radicals and freethinkers (illustrated by offering a chair of theology in the university to D. F. Strauss of Tübingen because of his *Life of Jesus*, then recently published) brought about a great reaction in 1839, when Zürich was the "Vorort." In Aargau the parties were very evenly balanced, and, when in 1840, on occasion of the revision of the constitution, the Radicals had a popular majority the aggrieved clerics stirred up a revoit (1840), which was put down, but which gave their opponents, headed by Augustine Keller, an excuse for carrying a vote in the great council to suppress the eight monasteries in the canton (Jan. 1841). This was flatly opposed to the pact of 1815, which the Diet by a small majority decided must be upheld (April 1841), though after many discussions it determined (Aug. 31, 1843) to accept the compromise by which the men's convents only were to be suppressed, and declared that the matter was now settled. On this the seven Romanist cantons—Uri, Schwyz, Unterwalden, Lucerne, Zug, Fribourg and the Valais—formed (Sept. 13, 1843) a "Sonderbund" or separate league, which (February 1844) issued a manifesto demanding the reopening of the question and the restoration of *all* the monasteries. Like the Radicals in former years the Romanists went too far and too fast, for in October 1844 the clerical party in Lucerne (in the majority since 1841, and favouring the reaction in the Valais) officially invited in the Jesuits and gave them high posts, an act which created all the more sensation because Lucerne was the "Vorort." Twice (December 1844 and March 1845) parties of free lances tried to capture the city. In December 1845 the Sonderbund turned itself into an armed confederation, ready to appeal to war in defence of the rights of each canton. The Radicals carried Zürich in April 1845 and Bern in February 1846, but a majority could not be secured in the Diet till Geneva (Oct. 1846) and St Gall (May 1847) were won by the same party. On the 20th of July 1847, the Diet, by a small majority, declared that the Sonderbund was contrary to the Federal pact, which on the 16th of August it was resolved to revise, while on the 3rd of September it was decided to invite each canton to expel the Jesuits. Most of the Great Powers favoured the Sonderbund, but England took the contrary view, and the attempt of Metternich, supported by Louis Philippe, to bring about European intervention, on the plea of upholding the treaties of Vienna, was frustrated by the policy of masterly inactivity pursued by Lord Palmerston, who delayed giving an answer till the forces of the Sonderbund had been defeated, a friendly act that is still gratefully remembered in the country. On the 29th of October the deputies of the unyielding cantons left the Diet, which ordered on the 4th of November that its decree should be enforced by arms. The war was short (Nov. 10–29), mainly owing to the ability of the general, G. H. Dufour (1787–1875), and the loss of life trifling. One after another the rebellious cantons were forced to surrender, and, as the Paris revolution of February 1848, entailing the retirement of Guizot (followed three weeks later by that of Metternich), occupied all the attention of the Great Powers (who by the constitution of 1815 should have been consulted in the revision of the pact), the Swiss were enabled to settle their own affairs quietly. Schwyz and Zug abolished their "landsgemeinden," and the seven were condemned to pay the costs of the war (ultimately defrayed by subscription), which had been waged rather on religious than on strict particularist or states-rights grounds. The Diet meanwhile debated the draft constitution drawn up by Johann Conrad Kern (1808–1888) of Thurgau and Henri Druey (1799–1855) of Vaud, which in the summer of 1848 was accepted by fifteen and a half cantons, the minority consisting of the three Forest cantons, the Valais, Zug, Tessin and Appenzell (Inner Rhoden), and it was proclaimed on the 12th of September.

Constitution of 1848.

The new constitution inclined rather to the Act of Mediation than to the system which prevailed before 1798. A status of "Swiss citizenship" was set up, closely joined to cantonal citizenship; a man settling in a canton not being his birthplace got cantonal citizenship after a residence of at most two years, but was excluded from all local rights in the "commune" where he might reside. A Federal or central government was set up, to which the cantons gave up a certain part of their sovereign rights, retaining the rest. The Federal Legislature (or assembly) was made up of two houses—the Council of States (*Ständerat*), composed of two deputies from each canton, whether small or great (44 in all), and the National Council (*Nationalrat*), made up of deputies elected for three years, in the proportion of one for every 20,000 souls or fraction over 10,000, the electors being all Swiss citizens. The Federal council or executive (*Bundesrat*) consisted of seven members elected by the Federal Assembly sitting as a congress; they were jointly responsible for all business, though for sake of convenience there were various departments, and their chairman was called the president of the Confederation. The Federal judiciary (*Bundesgericht*) was made up of eleven members elected for three years by the Federal Assembly sitting in congress; its jurisdiction was chiefly confined to civil cases, in which the Confederation was a party (if a canton, the Federal council may refer the case to the Federal tribunal), but took in also great political crimes—all constitutional questions, however, being reserved for the Federal Assembly. A Federal university and a polytechnic school were to be founded. All military capitulations were forbidden in the future. Every canton must treat Swiss citizens who belong to one of the Christian confessions like their own citizens, for the right of free settlement is given to all such, though they acquired no rights in the "commune." All Christians were guaranteed the exercise of their religion, but the Jesuits and similar religious orders were not to be received in any canton. German, French and Italian were recognized as national languages.

The constitution as a whole marked a great step forward; though very many rights were still reserved to the cantons, yet there was a fully organized central government. Almost the first act of the Federal Assembly was to exercise the power given them of determining the home of the Federal authorities, and on the 28th of November 1848 Bern was chosen, though Zürich still ranks as the first canton in the Confederation. Soon after 1848 a beginning was made of organizing the different public services, which had now been brought within the jurisdiction of the central Federal authority. Thus in 1849 a uniform letter post service was established, in 1850 a single coinage replaced the intricate cantonal currencies, while all customs duties between cantons were abolished; in 1851 the telegraph service was organized, while all weights and measures were unified (in 1868 the metrical system was allowed, and in 1875 declared obligatory and universal), in 1854 roads and canals were taken in hand, while finally in 1855 the Federal Polytechnic School at Zürich was opened, though the Federal university authorized by the new constitution has not yet been set up. These were some of the non-political benefits of the creation of a Federal central executive. But in 1852 the Federal Assembly decided to leave the construction of railways to private enterprise and so had to buy them up in 1903 at a vastly enhanced price.

By this early settlement of disputes Switzerland was protected from the general revolutionary movement of 1848, and in later years her political history has been uneventful, though she has felt the weight of the great European crises in industrial and social matters.

The position of Neuchâtel, as a member of the Confederation (as regards its government only) and as a principality ruled by the king of Prussia, whose rights had been expressly recognized by the congress of Vienna, was uncertain. She had not sent troops in 1847, and, though in 1848 there was a republican revolution there, the prince did not recognize the changes. Finally, a royalist conspiracy in September 1856 to undo the work of 1848 caused great excitement and anger in Switzerland, and it was only by the mediation of Napoleon III. and the other powers that the prince renounced (1857) all his rights, save his title, which his successor (the German emperor) has also dropped. Since that time Neuchâtel has been an ordinary member of the Confederation. In 1859–1860 the cession of Savoy (part of it neutralized in 1815) to France aroused considerable indignation, and in 1862 the long-standing question of frontiers in the Vallée des Dappes was finally arranged with France. In 1871 many French refugees, especially Bourbaki's army, were most hospitably received and sheltered. The growth of the Old Catholics after the Vatican Council (1870) caused many disturbances in western Switzerland, especially in the Bernese Jura. The attack was led by Bishop Eugène Lachat (1819–1886) of Basel, whose see was suppressed by several cantons in 1873, but was set up again in 1884 though still not recognized by Bern. The appointment by the pope of the abbé Gaspard Mermillod (1824–1892) as "apostolic vicar" of Geneva, which was separated from the diocese of Fribourg, led to Monseigneur Mermillod's banishment from Switzerland (1873), but in 1883 he was raised to the vacant see of Lausanne and Geneva and allowed by the Federal authorities to return, but Geneva refused to recognize him, though he was created a cardinal in 1890. An event of great importance to Switzerland was the opening of the St Gotthard tunnel, which was begun in 1871 and opened in 1882; by it the Forest cantons seem likely to regain the importance which was theirs in the early days of the Confederation.

From 1848 onwards the cantons continually revised their constitutions, always in a democratic sense, though after the Sonderbund War Schwyz and Zug abolished their "landsgemeinden" (1848). The chief point was the introduction of the *referendum*, by which laws made by the cantonal legislature may (facultative referendum) or must (obligatory referendum) be submitted to the people for their approval, and this has obtained such general acceptance that Fribourg alone does not possess the referendum in either of its two forms. It was therefore only natural that attempts should be made to revise the federal constitution of 1848 in a democratic and centralizing sense, for it had been provided that the Federal Assembly, on its own initiative or on the written request of 50,000 Swiss electors, could submit the question of revision to a popular vote. In 1866 the restriction of certain rights (mentioned above) to Christians only was swept away; but the attempt at final revision in 1872 was defeated by a small majority, owing to the efforts of the anti-centralizing party. Finally, however, another draft was better liked, and on the 19th of April 1874 the new constitution was accepted by the people—$14\frac{1}{2}$ cantons against $7\frac{1}{2}$ (those of 1848 without Tessin, but with Fribourg and Lucerne) and 340,199 votes as against 198,013. This constitution is still in force, and is mainly a revised edition of that of 1848, the Federal power being still further strengthened. Among the more important novelties three points may be mentioned. A system of free elementary education was set up, under the superintendence of the Confederation, but managed by the cantons. A man settling in another canton was, after a residence of three months only, given all cantonal and communal rights, save a share in the common property (an arrangement which as far as possible kept up the old principle that the "commune" is the true unit out of which cantons and the Confederation are built), and the membership of the commune carries with it cantonal and federal rights. The "Referendum" was introduced in its

Revised Constitution of 1874.

"facultative" form; *i.e.* all federal laws must be submitted to popular vote on the demand of 30,000 Swiss citizens or of eight cantons. But the "Initiative" (*i.e.* the right of compelling the legislature to consider a certain subject or bill) was not introduced into the Federal Constitution till 1891 (when it was given to 50,000 Swiss citizens) and then only as to a partial (not a total) revision of that constitution. By the constitutions of 1848 and 1874 Switzerland has ceased to be a mere union of independent states jointed by a treaty, and has become a single state with a well-organized central government, to which have been given certain of the rights of the independent cantons, but increased centralization would destroy the whole character of the Confederation, in which the cantons are not administrative divisions but living political communities. Swiss history teaches us, all the way through, that Swiss liberty has been won by a close union of many small states, and we cannot doubt that it will be best preserved by the same means, and not by obliterating all local peculiarities, nowhere so striking and nowhere so historically important as in Switzerland.

M. Numa Droz (who was for seventeen years—1876 to 1892—a member of the Federal executive, and twice, in 1881 and in 1887, president of the Swiss Confederation) expressed the opinion shortly before his death in December 1899 (he was born in 1844) that while the dominant note of Swiss politics from 1848 to 1874 was the establishment of a Federal state, that of the period extending from 1874 to 1899 (and this is true of a later period) was the direct rule of the people, as distinguished from government by elected representatives. Whether this distinction be just or not, it is certain that this advance towards democracy in its true sense is due indirectly to the monopoly of political power in the Federal government enjoyed by the Radical party from 1848 onwards: many were willing to go with it some part of the way, but its success in maintaining its close monopoly has provoked a reaction against it on the part of those who desire to see the Confederation remain a Confederation, and not become a strongly centralized state, contrary to its past history and genius. Hence after 1874 we find that democratic measures are not advocated as we should expect by the Radicals, but by all the other political parties with a view of breaking down this Radical monopoly, for it is a strange fact that the people elect and retain Radical representatives, though they reject the measures laid before them for their approval by the said Radical representatives. For these reasons the struggle between Federalists and Centralists (the two permanent political parties in Switzerland), which up to 1874 resulted in favour of the Centralists, has been turning gradually in favour of the Federalists, and that because of the adoption of such democratic institutions as the Referendum and the Initiative.

The general lines on which Swiss politics have run since 1874 may be most conveniently summarized under three headings—the working of the political machinery, the principal political events, and then the chief economical and financial features of the period. But it must be always borne in mind that all the following remarks relate only to *Federal* politics, those of the several cantons being much more intricate, and of course turning more on purely local differences of opinion.

1. *Political Machinery.*—The Federal Constitution of 1848 set up a permanent Federal executive, legislature and tribunal, each and all quite distinct from and independent of any cantonal government. This system was a modified revival of the state of things that had prevailed from 1798 to 1803, and was an imitation of the political changes that had taken place in the cantonal constitutions after 1830. Both were victories of the Centralist or Radical party, and it was therefore but natural that this party should be called upon to undertake the Federal government under the new constitution, a supremacy that it has kept ever since. To the Centralists the *Council of States* (two members from each canton, however large or small) has always been a stumbling-block, and they have mockingly nicknamed it "the fifth wheel of the coach." In the other house of the Federal legislature, the *National Council* (one member per 20,000, or fraction of over 10,000 of the entire population), the

Radicals have always since its creation in 1848 had a majority. Hence, in the Congress formed by both houses sitting together, the Radicals have had it all their own way. This is particularly important as regards the election of the seven members of the Federal executive which is made by such a Congress. Now the Federal executive (*Federal Council*) is in no sense a cabinet, *i.e.* a committee of the party in the majority in the legislature for the time being. In the Swiss Federal Constitution the cabinet has no place at all. Each member of the Federal executive is elected by a separate ballot, and holds office for the fixed term of three years, during which he cannot be turned out of office, while as yet but a single instance has occurred of the rejection of a Federal councillor who offered himself for re-election. Further, none of the members of the Federal executive can hold a seat in either house of the Federal legislature, though they may appear and speak (but not vote) in either, while the Federal Council as such has not necessarily any common policy, and never expresses its views on the general situation (though it does as regards particular legislative and administrative measures) in anything resembling the "speech from the Throne" in England. Thus it seems clear that the Federal executive was intended by the Federal Constitution of 1848 (and in this respect that of 1874 made no change) to be a standing committee of the legislature as a whole, but *not* of a single party in the legislature, or a "cabinet," even though it had the majority. Yet this rule of a single political party is just what has taken place. Between 1848 and the end of 1908, 38 Federal councillors were elected (24 from German-speaking, 12 from French-speaking and 2 from Italian-speaking Switzerland, the canton of Vaud heading the list with 7). Now of these 38 three only were not Radicals, viz. M Paul Ceresole (1870–1875) of Vaud, who was a Protestant Liberal-Conservative, Herren Josef Zemp (1891–1908) and Josef Anton Schobinger (elected 1908), both of Lucerne and Romanist Conservatives, yet the Conservative minority is a large one, while the Romanists form about two-fifths of the population of Switzerland. But despite this predominance of a single party in the Federal Council, no true cabinet system has come into existence in Switzerland, as members of the council do not resign even when their personal policy is condemned by a popular vote, so that the resignation of Herr Welti (a member of the Federal Council from 1867 to 1891), in consequence of the rejection by the people of his railway policy, caused the greatest amazement and consternation in Switzerland.

The chief political parties in the Federal legislature are the Right, or Conservatives (whether Romanists or Protestants), the Centre (now often called "Liberals," but rather answering to the Whigs of English political language, the Left (or Radicals) and the Extreme Left (or the Socialists of varying shades). In the Council of States there is always a Federalist majority, since in this house the smaller cantons are on an equality with the greater ones, each indifferently having two members. But in the National Council (167 elected members) there has always (since 1848) been a considerable Radical majority over all other parties. The Socialists long worked under the wing of the Radicals, but now in every canton (save Geneva) the two parties have quarrelled, the Socialist vote having largely increased, especially in the town of Zürich. In the country the anti-Radical opposition is made up of the Conservatives, who are strongest in the Romanist, and especially the Forest, cantons, and of the "Federalists" of French-speaking Switzerland. There is no doubt that the people are really anti-Radical, though occasionally led away by the experiments made recently in the domain of State socialism: they elect, indeed, a Radical majority, but very frequently reject the bills laid before them by their elected representatives.

2. *Politics.*—The cantons had led the way before 1848, and they continued to do so after that date, gradually introducing reforms all of which tended to give the direct rule to the people. The Confederation was bound to follow this example, though it adopted a far more leisurely pace. Hence, in 1872 a new Federal Constitution was drafted, but was rejected on a popular vote by a small majority, as it was thought to go too far in a centralizing direction, and so encountered the combined opposition of the Conservatives and of the Federalists of French-speaking Switzerland. The last-named party was won over by means of concessions as to military matters and the proposed unification of cantonal laws, civil and criminal, and especially by strong provisions as to religious freedom, since the "Kulturkampf" was then raging in French-speaking Switzerland. Hence a revised draft was accepted in 1874 by a considerable popular majority, and this is the existing Federal Constitution. But it bears marks of its origin as a compromise, and no one party has ever been very eager to support it as a whole. At first all went smoothly, and various very useful laws carrying out in detail the new provisions of the constitution were drafted and accepted. But divisions of opinion arose when it was proposed to reform the military system at a very great expenditure, and also as to the question of the limitation of the right to issue bank-notes, while (as will be seen under 3 below) just at this time grave financial difficulties arose with regard to the Swiss railways, and in consequence of Prince Bismarck's anti-free trade policy, which threatened the prosperity of Switzerland as an exporting country. Further, the disturbed political state of the canton of Ticino (or Tessin) became more or less acute from 1873 onwards. There the Radicals and the Conservatives are nearly equally balanced. In 1872 the Conservatives obtained the majority in this canton, and tried to assure it by some certainly questionable means. The Radicals repeatedly appealed to the Federal government to obtain its armed intervention, but in vain. In 1876 the Conservatives at a rifle match at Stabio fired on the Radicals, but in 1880 the accused persons were acquitted. The long-desired detachment of Ticino from the jurisdiction of the foreign dioceses of Como and Milan was effected in 1888 by the erection of a see at Lugano, but this event caused the Radicals to fear an increase of clerical influence. Growing impatient, they finally took matters in their own hands, and in September 1890 brought about a bloody revolution. The partial conduct of the Radical Federal commissioner was much blamed, but after a state trial at Zürich in 1891 the revolutionists were acquitted, although they loudly boasted of their share in this use of force in political matters.

From 1885 onwards Switzerland had some troubles with foreign powers owing to her defence of the right of asylum for fugitive German Socialists, despite the threats of Prince Bismarck, who maintained a secret police in Switzerland, one member of which, Wohlgemuth, was expelled in 1889, to the prince's huge but useless indignation. From about 1890, as the above troubles within and without gradually subsided, the agitation in the country against the centralizing policy of the Radicals became more and more strongly marked. By the united exertions of all the opposition parties, and against the steady resistance of the Radicals, an amendment was introduced in 1891 into the Federal Constitution, by which 50,000 Swiss citizens can by the "Initiative" *compel* the Federal legislature and executive to take into consideration some point in the Federal Constitution which, in the opinion of the petitioners, requires reform, and to prepare a bill dealing with it which must be submitted to a popular vote. Great hopes and fears were entertained at the time as to the working of this new institution, but both have been falsified, for the Initiative has as yet only succeeded in inserting (in 1893) in the Federal Constitution a provision by which the Jewish method of killing animals is forbidden, and another (in 1908) prohibiting the manufacture or sale of absinthe in the country. On the other hand, it has failed (in 1894) to secure the adoption of a Socialist scheme by which the state was bound to provide work for every able-bodied man in the country, and (also in 1894) to carry a proposal to give to the cantons a bonus of two francs per head of the population out of the rapidly growing returns of the customs duties, similarly in 1900 an attempt to introduce the election of the Federal executive by a popular vote and proportional representation in the *Nationalrat* failed, as in 1903 did a proposal to make the elections to the *Nationalrat* depend on the Swiss population only, instead of the total population of the country.

The great rise in the productiveness of the customs duties (see 3 below) has tempted the Swiss people of late years to embark on a course of state socialism, which may be also described as a series of measures tending to give more and more power to the central Federal government at the expense of the cantons. So in 1890 the principle of compulsory universal insurance against sickness and accidents was accepted by a popular vote, in 1891 likewise that of a state or Federal bank, and in 1898 that of the unification of the cantonal laws, civil and criminal, into a set of Federal codes. In each case the Federal government and legislature were charged with the preparation of laws carrying out in detail these general principles. But in 1897 their proposals as to a Federal bank were rejected by the people, though another draft was accepted in 1905, so that the bank (with a monopoly of note issue, a provision accepted by a popular vote in 1891) was actually opened in 1907. At the beginning of 1900 the suspicion felt as to the insurance proposals elaborated by the Federal authorities was so keen that a popular demand for a popular vote was signed by 117,000 Swiss citizens, the legal minimum being only 30,000: they were rejected (May 20, 1900) on a popular vote by a nearly two to one majority. The preparation of the Federal civil and criminal codes has progressed quietly, drafts being framed by experts and then submitted for criticism to special commissions and public opinion, but finally the civil code was adopted by the Federal Assembly in December 1907. By a popular vote in 1887 the Federal authorities were given a monopoly of alcohol, but a proposal to deal similarly with tobacco has been very ill received (though such a monopoly would undoubtedly produce a large amount), and would pretty certainly be refused by the people if a popular vote were ever taken upon it. In 1895 the people declined to sanction a state monopoly of matches, even though the unhealthy nature of the works was strongly urged, and have also resolutely refused on several occasions to accept any projects for the centralizing of the various branches of military administration, &c., though in 1897 the forests high up on the mountains were placed under Federal supervision, while in 1902 large Federal grants in aid were made to the cantons towards the expenses of primary education, and in 1908 the supervision of the employment of the power derived from rivers and streams was given to the Confederation. Among other reforms which have recently been much discussed in Switzerland are the introduction of the *obligatory* referendum (which hitherto has applied only to amendments to the Federal Constitution) and the extension of the initiative (now limited to piecemeal revision of the Federal Constitution) to *all* Federal laws, &c. The first-named scheme is an attempt to restrain important centralizing measures from being presented as laws (and as such exempt from the compulsory referendum), and not as amendments to the Federal Constitution.

Besides the insurance project mentioned above, two great political questions have engaged the attention of the Swiss.

a. State Purchase of the Railways.—In 1891 the purchase of the Central railway was rejected by a popular vote, but in 1898, by the aid of various baits thrown out, the people were induced to accept the principle of the purchase by the Confederation of the five great Swiss railway lines—three in 1901, viz. the Central, the North-Eastern, and the United Swiss lines; one (the Jura-Simplon) in 1903, and one (the St Gotthard line) in 1909, this delay being due to international conventions that still have some years to run. Further, very important economical consequences, *e.g.* as to strikes, may be expected to result from the transformation of all railway officials of whatever grade into state servants, who may naturally be expected to vote (as in other cases) for their employers, and so greatly increase the strength of the Centralist political party.

b. The " Double Initiative."—This phrase denotes two purely political reforms that have been coupled together, though in reality they are by no means inseparable. One is the introduction of proportional representation (within the several cantons) into the elections for the National Council of the Federal parliament, the object being thus to secure for several large minorities a number of M.P.'s more in accordance with the size of those minorities in the country than is now possible under the régime of pure majorities: naturally these minorities would then receive a proper share of political power in the senate house, instead of merely exerting great political influence in the country, while if they were thus strengthened in the legislature they would soon be able to claim the right of naming several members of the Federal executive, thus making both legislature and executive a mirror of the actual political situation of the country, instead of the preserve of one political party. The other reform is the election of the members of the Federal executive by popular vote, the whole body of voters voting, not by cantons, but as a single electoral constituency. This would put an end to the " lobbying " that goes on previously to the election of a member of the executive by the two houses of the Federal parliament sitting jointly in Congress; but, on the other hand, it might stereotype the present system of electing members of the executive by the majority system, and so reduce large minorities to political impotence. The " double initiative " scheme was launched in the beginning of 1899, and by the beginning of the following July secured more than the requisite number of signatures (50,000), the first-named item having been supported by nearly 65,000 citizens, and the second item by 56,000. Hence the Federal parliament was *bound* to take these two reforms into formal consideration, but in June 1900 it rejected both, and this decision was confirmed by a popular vote taken in the following November.

3. *Economics and Finance.*—Soon after the adoption of the Federal Constitution of 1874 the economical and financial state of the Confederation became very unsatisfactory. The great financial crisis in Vienna in 1873 was a severe blow to Swiss commerce, which had taken a very great start after the Franco-German War of 1870–71. In the later 'seventies, too, the financial position of some of the great Swiss railway lines was very unfavourable: the bankruptcy of the National line ruined for the time (till a Federal loan at a very low rate of interest was forced upon them) the four Swiss towns which were its guarantors; the North-Eastern line had to beg for a "moratorium" (a *legal* delay of the period at which it had to pay its debts) from the Federal government; the Bern-Lucerne line was actually put up to auction, and was bought by the canton of Bern. Further, the expenses of constructing the St Gotthard railway vastly exceeded all estimates, and in 1876 over 100,000,000 francs more were required. Hence the subventions already granted had to be increased. Germany (which gave originally 20,000,000 francs) and Italy (original contribution 45,000,000 francs) each promised 10,000,000 francs more; the St Gotthard company itself gave 12,000,000, and the two Swiss railway lines interested (Central and North-Eastern) added 1,500,000 to the 20,000,000 they had already agreed to give jointly with the cantons interested in the completion of this great undertaking. But these latter refused to add anything to their previous contributions, so that finally the Federal government proposed that it should itself pay the 6,500,000 francs most urgently required. This proposal aroused great anger in east and west Switzerland, but the matter was ultimately settled by the Confederation paying 4,500,000 francs and the interested cantons 2,000,000, the latter gift being made dependent on a grant of 4,500,000 francs by the Federal government for new tunnels through the Alps in east and west Switzerland, and of 2,000,000 more for the Monte Cenere tunnel between Bellinzona and Lugano. This solution of a most thorny question was approved by a popular vote in 1879, and the St Gotthard line was successfully completed in 1882. Gradually, too, the other Swiss railway lines, attained a state of financial equilibrium, owing to the more careful management of new directors and managers. The completion of the Simplon tunnel (1906), the commencement (1906) of that beneath the Lötschen Pass (*q.v.*), and the rival claims of projected tunnels under the Splügen Pass (*q.v.*), besides the struggle for or against a tunnel under the Faucille (supported by Geneva almost alone), show that railway politics play a very prominent part in Swiss national life. They are, too, complicated by many local rivalries, which in this country are of greater importance than

elsewhere because of the considerable share of power still legally belonging to the cantons. Another kindred question (owing to the rapid development of electric traction in Switzerland) is the equitable proposal (accepted in 1908) that the utilization of the immense force supplied by the many rivers and torrents in Switzerland should become a Federal monopoly, so as to secure to the Confederation the control over such important sources of revenue as otherwise might easily be unscrupulously exploited by private companies and firms.

Switzerland, by reason of natural conditions, is properly a free trade country, for it exports far more than it imports, in order to supply the demand for objects that it cannot itself produce. But Prince Bismarck's protectionist policy in 1879 was imitated by France, Austria and Italy, so that Switzerland was gradually shut in by a high wall of tariffs. Hence in 1891 the Swiss people approved, in sheer self-defence, a great increase of the customs duties, and in 1903 sanctioned a further very considerable advance in these duties, so that it is now a thoroughly Protectionist country, despite its obvious natural disadvantages. The huge increase in revenue naturally led to increased expenditure, which took the form of lavish subventions to all sorts of cantonal objects, magnificent Federal buildings, most useful improvements in the post and telegraph services, and extensive and lamentable construction of military fortifications in Uri and the Valais against some unknown foe. In 1894 it was proposed to distribute part of this new wealth in giving a bonus to the cantons at the rate of 2 francs per head of the population, but this extravagant proposal (nicknamed the "Beutezug") was rejected, owing to the cool common sense of the Swiss people, by a majority of over two to one. These prosperous circumstances, however, contributed mainly to the adoption or suggestion of various measures of state socialism, *e.g.* compulsory sick insurance, Federal subvention to primary schools, purchase of the five great Swiss railway lines, giving a right to every able-bodied man to have work at the expense of the state, subventions to many objects, &c. (W. A. B. C.)

Literature

There is no such thing as a Swiss national vernacular literature properly speaking, this being explained by the diversity between the states of which it is composed, which has not favoured any common intellectual life. But there are four branches which make up a literature of Switzerland, distinguished according to the language in which the works in each are composed. As the Confederation, from its foundation in 1291 till 1798, was exclusively composed (with a partial exception in the case of Fribourg) of German-speaking districts, the real Swiss vernacular literature (if any one branch is to be dignified by that name) is in German, though in the 18th century French became the fashionable language in Bern and elsewhere, while the influence of the French-speaking "allies" and subject lands was more marked than before. Hence the German branch is by far the more important and more national, while the French branch is not really Swiss till after 1815, when these regions took full rank as cantons. Thus Geneva and Lausanne in the 18th century, with their respective brilliant societies, were only "Swiss" in so far as Geneva was an "ally" and Vaud a "subject land." The Italian and Romonsch-Ladin branches are of not sufficient importance to deserve more than a passing notice.

a. German Branch.—It is noticeable that while the original League of 1291 (like the earlier charters of liberties to the first members of the Confederation) is drawn up in Latin, all later alliances among the cantons, as well as documents concerning the whole Confederation (the Parsons' Ordinance of 1370, the Sempach Ordinance of 1393, and the Compact of Stans 1481) and all the Recesses of the Diets are compiled in German. Though such political documents are not "literature," yet they show that these early pre-Reformation alliances rested on the popular consent, and so were expressed in vernacular German rather than in clerkly Latin. But this vigorous popular life found other channels in which to develop its energy. First in order of date are the Minnesingers, the number of whom in the districts that ultimately formed part of the medieval Swiss Confederation are said to have exceeded thirty. Zürich then (as now) was the chief literary centre of the Confederation. The two Manesses (father and son) collected many of their songs in a MS. that has happily come down to us and is preserved in Paris. The most prominent personage of this circle of the muses was Master John Hadlaub, who flourished in the second half of the 13th and the first quarter of the 14th centuries. Next we have a long series of war songs, celebrating the marvellous victories of the early Swiss. One of the earliest and most famous of these was composed by Hans Halbsuter of Lucerne to commemorate the glorious fight of Sempach (1386), not far from his native town. There are other similar songs for the victory of Näfels (1388) and those of Grandson and Morat (both 1476) in the Burgundian War, while in the 14th century the Dominican friar Ulrich Boner of Bern versified many old fables. Still more important are the historical chronicles relating to different parts of Switzerland. Thus in the 14th century we have Christian Kuchimeister's continuation of the annals of the famous monastery of St Gall, in the early 15th century the rhymed chronicle of the war between the Appenzellers and the abbot of St Gall, and rather later in the same century the chronicles of Conrad Justinger of Bern and Hans Fründ (d. 1469) of Lucerne, besides the fantastical chronicle of Strättligen and a scarcely less fanciful poem on the supposed Scandinavian descent of the men of Schwyz and of Ober Hasle, both by Eulogius Kiburger (d. 1506) of Bern. In the 15th century, too, we have the *White Book* of Sarnen and the first Tell song (see TELL), which gave rise to the well-known legend, as well as the rather later play named the *Urnerspiel* dealing with the same subject. The Burgundian War witnessed a great outburst of historical ardour in the shape of chronicles written by Diebold Schilling (d. 1486) of Bern, by Melchior Russ (d. 1499), Diebold Schilling (d. between 1516 and 1523) and Petermann Etterlin (d. 1509), all three of Lucerne as well as by Gerold Edlibach (d. 1530) of Zürich, and by Johnanes Lenz (d. 1541) of Brugg. In the vernacular, too, are the earliest descriptions of the Confederation, those by Albert von Bonstetten of Einsiedeln (1479) and by Conrad Türst of Zürich (1496), to whom also we owe the first map of the country (1495–1497).

The Swiss Humanists wrote naturally in Latin, as did also, what was more surprising, the Swiss Reformers, at any rate for the most part, though the Zürich Bible of 1531 forms a striking exception. But Nicholas Manuel (1484–1530), a many-sided Bernese, composed satirical poems in German against the pope, while Valerius Anshelm (d. 1540), also of Bern, wrote one of the best Swiss chronicles extant. Giles Tschudi (*q.v.*) of Glarus, despite great literary activity, published but a single German work in his lifetime—the *Uralt warhafftig Alpisch Rhaetia sampt dem Tract der anderen Alpgebirgen* (1538)—besides his map of Switzerland (same date). Sebastian Münster (*q.v.*), who was a Swiss by adoption, published (1544) his *Cosmographia* in German, the work being translated into Latin in 1550. But the many-sided Conrad Gesner (*q.v.*), a born Swiss, wrote all his works in Latin, German translations appearing only at a later date. Thus the first important original product in German was the very remarkable and elaborate history and description of Switzerland, issued in 1548 at Zürich by Johannes Stumpf (*q.v.*) of that town. But Josias Simler (*q.v.*), who was in a way his continuator, wrote all his works, theological and geographical, in Latin. Matthew Merian (*q.v.*) engraved many plates, which were issued in a series of volumes (1642–1688) under the general title of *Topographia*, the earliest volume describing Switzerland, while all had a text in German by an Austrian, Martin Zeiller. Very characteristic of the age are the autobiography of the Valais scholar Thomas Platter (1499–1582) and the diary of his still more distinguished son Felix (1536–1614), both written in German, though not published till long after. But gradually Swiss historical writers gave up the use of Latin for their native tongue, so Michael Stettler (1580–1642) of Bern, Franz Haffner (1609–1671) of Soleure, and quite a number of Grisons authors (though the earliest in date, Ulrich Campell of Süs, *c.* 1509–*c.* 1582, still clung to Latin), such as Bartholomew Anhorn (1566–1640) and his son of the same name (1616–1670) and Johannes Guler (1562–1637). Yet Fortunatus Sprecher (1585–1647) preferred to write his *Pallas raetica* in Latin, as did Fortunatus Juvalta (1567–1654) in the case of his autobiography. But we have some compensation in the delightful autobiography of Hans Ardüser of Davos (1557–post 1614) and the amusing dialogue between the Niesen and the Stockhorn by Hans Rudolf Rebmann (1566–1605), both composed in naïve German. J. B. Plantin (1625–1697) wrote his description of Switzerland in Latin, *Helvetia nova et antiqua* (1656), but J. J. Wagner's (1641–1695) guide to Switzerland is in German, despite its titles *Index memorabilium Helvetiae* (1684) and *Mercurius helveticus* (1688), though he issued his scientific description of his native land in Latin, *Historia naturalis Helvetiae curiosa* (1680).

In the 18th century the intellectual movement in Switzerland greatly developed, though it was naturally strongly influenced by local characteristics. Basel, Bern and especially Zürich were the chief literary centres. Basel was particularly distinguished for its mathematicians, such as Leonhard Euler (1707–1783, *q.v.*) and three members of the Bernoulli family (*q.v.*) refugees from Antwerp, the brothers Jakob (1654–1705) and Johannes (1667–1748), and the latter's son Daniel (1700–1782). But its chief literary glory was Isaac Iselin (1728–1783), one of the founders of the Helvetic Society

(1760) and of the Economical Society (1777), and author of a treatise on the philosophy of history entitled *Geschichte der Menschheit* (1764), and of another on ideal politics, *Philosophische und patriotische Träume eines Menschenfreundes* (1755), while many of his economical tracts appeared (1776–1782) under the general title of *Ephemeriden der Menschheit.* At Bern Albrecht von Haller (*q.v.*), though especially distinguished as a scientific writer, yet by his poem *Die Alpen* (1732) and his travels in his native country did much to excite and stimulate the love of mountain scenery. Another Bernese, Charles Victor de Bonstetten (*q.v.*), is a type of the gallicized Liberal Bernese patrician, while Beat Ludwig von Muralt (1665–1749) analysed the racial characteristics of other nations for the instruction of his fellow-countrymen, his *Lettres sur les anglais et les français* (1725) being his principal work. Samuel Wyttenbach (1748–1830) devoted himself to making known the beauties of his country to its natives, travelling much and writing much about his travels. Gottlieb Sigmund Gruner (*q.v.*) wrote the *Eisgebirge des Schweizerlandes* (1760), a work describing the ice-clad mountains of Switzerland, though it is rather a useful compilation than an original contribution to knowledge, but a decided advance on his fellow Bernese Johann Georg Altmann's (1697–1758) *Versuch einer historischen und physischen Beschreibung der helvetischen Eisgebirge* (1751). In another department of knowledge a son of Albrecht von Haller, Gottlieb Emmanuel von Haller (1735–1786), compiled a most useful bibliography of writings relating to Swiss history, the *Bibliothek der Schweizergeschichte* (6 vols., 1784–1787), that is still indispensable to the historical student.

But in the 18th century Zürich was undoubtedly the intellectual and literary capital of German-speaking Switzerland, and gained the title of "Athens on the Limmat." One of its earliest and most famous celebrities was J. J. Scheuchzer (*q.v.*), who travelled much in Switzerland, and wrote much (his travels are described in Latin) as to its natural curiosities, being himself an F.R.S., and closely associated with Newton and the other English scientific men of the day. But in the purely literary domain the names of J. J. Bodmer (*q.v.*) and of his friend Johann Jakob Breitinger (1701–1776), are the most prominent. By their united exertions the antiquated traditions of German literature were broken down to a large extent, while great praise was bestowed on English poets, Shakespeare, Milton and others. Their views were violently opposed by Gottsched, the leader of the Saxon school, and the controversy that arose forms part of the history of German literature. In 1721–1723 they published jointly the *Discourse der Maler*, a periodical which spread their views, while more elaborate and systematic expositions of their critical doctrine as to poetry are Bodmer's *Kritische Abhandlung von dem Wunderbaren in der Poesie* (1740), and Breitinger's *Critische Dichtkunst* (also in 1740). Their untiring efforts helped to prepare the way for the later outburst of German literature begun by Klopstock, Wieland and Lessing. Another famous Zürich writer was Solomon Gesner (*q.v.*), the pastoral poet, and yet another was J. K. Lavater (*q.v.*), now best remembered as a supporter of the view that the face presents a perfect indication of character and that physiognomy may therefore be treated as a science. Other well-known Zürich names are those of J. H. Pestalozzi (1746–1827, *q.v.*), the educationalist, of Johann Caspar Hirzel (1725–1803), another of the founders of the Helvetic Society, and author of *Die Wirthschaft eines philosophischen Bauers* (1761), and of Johann Georg Sulzer (1720–1779), whose chief work is one on the laws of art or aesthetics, entitled *Allgemeine Theorie der schönen Künste* (1771–1774).

Outside the three towns named above there were several writers of German-speaking Switzerland who must be mentioned. One of the best known even now is Johann Georg Zimmermann (1728–1795 *q.v.*), whose *Betrachtungen über die Einsamkeit* (1756–1784–1785) profoundly impressed his contemporaries. He, like the fabulist A. E. Fröhlich (*q.v.*), was born at Brugg. Johannes von Müller (*q.v.*) of Schaffhausen, was the first who attempted to write (1780) a detailed history of Switzerland, which, though inspired rather by his love of freedom than by any deep research, was very characteristic of his times. J. G. Ebel (*q.v.*) was a Swiss by adoption only, but deserves mention as the author of the first detailed guide-book to the country (1793), which held its ground till the days of "Murray" and "Baedeker." A later writer, Heinrich Zschokke (1771–1848), also a Swiss by adoption only, produced (1822) a history of Switzerland written for the people, which had a great vogue.

In the later literary history of German-speaking Switzerland three names stand out above all others—Albrecht Bitzius (*q.v.*), known as Jeremias Gotthelf from the first of his numerous tales of peasant life in the Emmenthal, Gottfried Keller (*q.v.*), perhaps the most genuinely Swiss poet and novelist of the century, and Conrad Ferdinand Meyer (*q.v.*), also a poet and novelist, but of more cosmopolitan leanings and tastes. Jakob Burckhardt (*q.v.*) was a famous writer on Italian art, while Jakob Frey (1824–1875) continued the work of Bitzius by his tales of Swiss peasant life. Ulrich Hegner (1759–1840) of Winterthur wrote novels full of local colour, as is also the case with David Hess (1770–1843) in his description of a cure at Baden in Aargau and various tales. Johann Martin Usteri (1763–1828) of Zürich was one of the earliest to write poems in his native dialect. Later we have a number of Zürich poets or versifiers, some of whose writings have become very well known. Such were Heinrich Leuthold (1827–1879), August Corrodi (1826–1885) and Leonhard Widmer (1808–1868), the author of *Trittst im Morgenrot daher* (1842), which, set to music by the Cistercian monk Alberic Zwyssig (1808–1854), is now known as the "Swiss Psalm," of *Es lebt in jeder Schweizerbrust* (1842), and *Wo Berge sich erheben* (1844). To the Bernese poet, Johann Rudolf Wyss (1781–1830), whose father, J. D. Wyss (1743–1818), was the author of the *Swiss Family Robinson*, we owe the Swiss national anthem, *Rufst du mein Vaterland?* and the song, *Herz, myn Herz, warum so trurig?*—while Johann Georg Krauer (1792–1845), of Lucerne, wrote the Rütlilied, *Von ferne sei herzlich gegrüsset*, and Gottfried Keller himself was responsible for *O mein Heimatland.* Gottlieb Jakob Kuhn (1775–1845) wrote many poems in the Bernese dialect as to the Alps and their inhabitants. Less national in sentiment and more metaphysical are the lyrics of "Oranmor," the pen-name of the Bernese Ferdinand Schmid (1823–1888).

Among the chief contemporary Swiss writers in the department of belles-lettres, novelists, poets, &c., may be mentioned Ernst Zahn, Meinrad Lienert, Arnold Ott, Carl Spitteler, Fritz Marti, Walther Siegfried, Adolf Frey, Hermann Hesse, J. C. Herr, J. V. Widmann, and Gottfried Strasser.

Isabella Kaiser, by her poems and stories, upholds the honour of the fair sex, while the fame won by Johanna Spyri (d. 1891) for her children's stories is still fresh. Of historical writers in different departments of their subject in the course of the 19th century some of the principal were (in alphabetical order): Ildefons von Arx (1755–1833), the historian of St Gall, of which he had been a monk, E. Blösch (1838–1900), the historian of the Protestant churches in German-speaking Switzerland, J. J. Blumer (1819–1875), and J. C. Bluntschli (1808–1881), who both devoted their energies to Swiss constitutional matters, J. J. Hottinger (1783–1860), the continuator of J. von Müller's Swiss history, J. E. Kopp (1793–1866), who rewrote early Swiss history on the basis of authentic documents, R. Maag (1866–1899), who began the publication of the invaluable Habsburg terrier of the early 14th century, but had to leave the completion of the work to other competent hands, P. C. von Planta (1815–1902) and J. A. Pupikofer (1797–1882), the historians respectively of the Grisons and of the Thurgau, A. P. von Segesser (1817–1888), the historian and statesman of Lucerne, A. F. Stettler (1796–1849), A. von Tillier (1792–1854), E. von Wattenwyl (1815–1890), and J. L. Wurstemberger (1783–1862) who all four wrote on Bernese history, G. von Wyss (1816–1893), to whom we owe, among many excellent works, an admirable account of all Swiss historians and their works, his step-brother F. von Wyss (1818–1907), a great authority on the legal and constitutional history of Switzerland, and J. C. Zellweger (1768–1855), the historian of Appenzell. Among contemporary historical writers of German-speaking Switzerland we may mention (in alphabetical order), A. Büchi, J. L. Brandstetter, W. Burckhardt, K. Dändliker, J. Dierauer, R. Durrer, H. Escher, A. Heusler, R. Hoppeler, T. von Liebenau, W. Merz, G. Meyer von Knonau, W. F. von Mülinen, W. Oechsli, J. R. Rahn, L. R. von Salis, P. Schweizer, J. Schollenberger, J. Strickler, R. Thommen, and H. Wartmann.

b. French Branch.—The knight Othon of Grandson is the earliest figure in the literature of the *Suisse romande.* He was killed in a judicial duel in 1397, the last scion of his ancient house, and left some amatory poems behind him, while one is extant only in a translation by Chaucer, who makes flattering mention of him. In the 15th and 16th centuries many miracle plays in the local Romance dialect were known. The *Chronique des chanoines de Neuchâtel* was formerly supposed to date from the 15th century, but is now considered by many to be a forgery. More individual and characteristic are the romance about Charlemagne, entitled *Fierabras le Géant* (1478), by Jean Bagnyon, and the poem named *Congié pris du siècle séculier* (1480), by Jacques de Bugnin. But the first really prominent personage in this department of literature is François Bonivard (*q.v.*; d. 1570) who wrote the *Chroniques de Genève* that extend down to 1530 and were continued to 1562 by Michel Roset (d. 1613). The first Protestant French translation of the Bible was issued at Neuchâtel in 1535, its principal authors being Pierre Robert (nicknamed Olivétan) and Pierre de Vingle. As a sort of pendant to the Protestant Bonivard, we have the nun Jeanne de Jussie who in her *Levain du Calvinisme* (*c.* 1545) recounts the establishment of Calvinism at Geneva, while the noble Pierre de Pierrefleur in his *Mémoires* does the same in a lighter and less lachrymose style for Orbe, his native district. Naturally the Reformers of the Suisse Romande used French much in their theological and polemical works. Of more general interest are the writings of two Frenchmen who were driven by religious persecutions to end their lives at Geneva—the memoirs and poems of Théodore Agrippa d'Aubigné (1552–1630), and the historical writings and poems of Simon Goulart (1543–1628). The great deliverance of Geneva from the duke of Savoy, known as the Escalade (1602), was described in prose by David Piaget (1580–1644) in his *Histoire de l'escalade* and celebrated in verse by Samuel Chappuzeau (1625–1701) in his *Genève délivrée*, though the narratives of Goulart and that (published officially by the government) attributed to Jean Sarasin (1574–1632), the author of the *Citadin de Genève* (1606), are more laconic and more striking. J. B. Plantin (1625–1697), of Vaud, wrote his topography of Switzerland, *Helvetia antiqua et nova* (1656), in Latin, but his *Abrégé de l'histoire générale de la Suisse* (1666) in French, while Georges de Montmollin (1628–1703) of Neuchâtel wrote, besides various works as to local history, *Mémoires* of his times which have a certain historical value.

But the 17th century in the Suisse Romande pales before the glories of the 18th century, which forms its golden age, and was in a large degree due to the influence of French refugees who, with their families, flocked thither after the Revocation of the Edict of Nantes (1685) and settled down there for the rest of their lives. Such was Louis Bourguet (1678–1743), who, besides his geological works, founded two periodicals which in different ways did much to stimulate the intellectual life of the Suisse Romande; these were the *Bibliothèque italique* (1729–1734), which aimed at making more widely known the results of Italian research, and the *Mercure suisse* which, first issued in 1732, lasted till 1784, under different names (from 1738 onwards the literary section bore the name of *Journal helvétique*), and secured contributions from most of the leading writers of the Suisse Romande of the day, such as Firmin Abauzit (1679–1767), Abraham Ruchat (1678–1750), and others. Ruchat is now best remembered as the author (under the pen-name of Gottlieb Kypseler) of an excellent guide-book to Switzerland, the *Délices de la Suisse*, which first appeared in 1714 and passed through many editions, the latest being issued in 1778; but his *Histoire de la Réformation de la Suisse* (1727–1728) was much esteemed in his day. Another Vaudois historian and antiquary was Charles Guillaume Loys de Bochat (1695–1754) whose *Mémoires critiques sur divers points de l'ancienne histoire de la Suisse* (1747–1749) still form a treasure-house for archaeologists. Yet a third Lausanne man was J. P. de Crousaz (1663–1750; *q.v.*), who introduced there the philosophy of Descartes, and was, by his books, the master of Gibbon in logic. A French refugee at Lausanne, Jean Barbeyrac (1674–1744), published in 1712 the *Droit de la nature et des gens*, a translation of Puffendorf's treatise, with a striking preface of his own. A precursor of Montesquieu and of Rousseau was Jean Jacques Burlamaqui (1694–1750) in his *Principes du droit naturel et politique* (1747 and 1751, issued together in 1763), while the celebrated international lawyer, Eméric de Vattel (1714–1767), was a native of Neuchâtel by birth and descent, and, though he spent most of his life at foreign courts, died at Neuchâtel, not so very long after the publication of his famous *Droit des gens* (1758).

The year 1754 is a great date in the literary history of the Suisse Romande, for in that year Rousseau came back for good to Geneva, and Voltaire established himself at Ferney, while in 1753 Gibbon had begun his first residence (which lasted till 1758) in Lausanne. The earlier writers mentioned above had then nearly all disappeared, and a more brilliant set took their place. But Rousseau (*q.v.*), though a Genevese, belongs rather to European than to Swiss literature, as do later Jacques Necker (*q.v.*) and his daughter, Madame de Staël (*q.v.*), Benjamin Constant (*q.v.*) and Sismondi (*q.v.*). Madame de Charrière (1740–1805) was Dutch by birth, but married to a native of Neuchâtel. Among her earlier works were two novels, *Le Mari sentimental* (1783), and the *Lettres de Mistress Henley* (1784), both of which had a great vogue in their day and paint, from her own experience, the sad results of an unsuitable marriage. More celebrated by reason of the liveliness and acuteness with which the manners of a little provincial town are described are her *Lettres de Lausanne* (1871), and her *Lettres neuchâteloises* (1784), particularly the second part of a story of the former, entitled *Caliste*, and published in 1788, for, according to Sainte-Beuve, it was a sort of foreshadowing of the more famous *Corinne* (1807) of Madame de Staël. P. H. Mallet (*q.v.*), a Genevese, who held a chair at Copenhagen, devoted himself to making known to the educated world the history and antiquities of Scandinavia. But more characteristic of Geneva were the efforts of a group of men to spread the cause of natural science by personal investigations in the higher Alps, then but little known. Possibly their interest in such matters had been stimulated by the scientific and psychological speculations of Charles Bonnet (*q.v.*). The chief of this school was H. B. de Saussure (*q.v.*) one of the founders of geology and meteorology, while his Alpine ascents (undertaken in the cause of science) opened a new world even to non-scientific travellers. The brothers De Luc (*q.v.*) devoted themselves mainly to questions of physics in the Alps, while Senebier (*q.v.*), the biographer of Saussure, was more known as a physiologist than as a physicist, though he wrote on many branches of natural science, which in those days was not yet highly specialized. On the other hand Marc Théodore Bourrit (*q.v.*), the contemporary of these three men, was rather a curious and inquisitive traveller than a scientific investigator, and charms us even now by his genial simplicity as contrasted with the austerity and gravity of the three writers we have mentioned. Philippe Cyriaque Bridel (1757–1845), best known as the "doyen Bridel," was the earliest of the Vaudois poets by virtue of his *Poésies helvétiennes* (1782). But he is better known as the painter of the scenery and people among whom he worked as pastor at Basel, at Château d'Oex, and at Montreux successively. His *Course de Bâle à Bienne par les vallées du Jura* appeared in 1802, while descriptions of his travels, as well as of the manners of the natives, local history, and in short everything that could stimulate national sentiment, were issued in a series of periodicals from 1783 to 1831 under the successive titles of *Étrennes helvétiennes* and of *Conservateur suisse*. His patriotic aim met with great success, while his impressions of his mountain wanderings are fresh and unspoilt by any straining after effect. He was the first writer of the Suisse Romande to undertake such wanderings, so that, with obvious differences, he may be regarded not merely as the forerunner, but as the inspirer and model of later Vaudois travellers and climbers in the Alps, such as Rodolphe Töpffer (*q.v.*), of E. Rambert (*q.v.*), and of the last-named's most brilliant pupil, Émile Javelle (1844–1883), whose articles were collected in 1886 by the pious care of his friends under the title of *Souvenirs d'un alpiniste*. As a poet Juste Olivier (*q.v.*) surpassed Bridel. Nor can we wonder that with the advance of knowledge Bridel's history is found to be more picturesque than scientific. Two Vaudois, Charles Monnard (1790–1865) and Louis Vulliemin (1797–1879) carried out their great scheme of translating (1837–1840) J. von Müller's Swiss history with its continuation by Hottinger, and then completed it (1841–1851) down to 1815. This gigantic task did not, however, hinder the two friends from making many solid contributions to Swiss historical learning. Later in date were Alexandre Daguet (1816–1894) who wrote an excellent history of Switzerland, while Jean Joseph Hisely (1800–1866), Albert Rilliet (1809–1883), and Pierre Vaucher (1833–1898), all devoted much labour to studying the many problems offered by the early authentic history (from 1291 onwards) of the Swiss Confederation. A different type of history is the work of an honest but partisan writer, the Genevese Jules Henri Merle d'Aubigné (1794–1872), entitled *Histoire de la réformation au temps de Calvin* (1835–1878). The Vaudois noble Frédéric Gingins-la-Sarra (1790–1863) represents yet another type of historian, devoting himself mainly to the medieval history of Vaud, but occasionally going beyond the numberless authentic documents brought to light by him, and trying to make them prove more than they can fairly be expected to tell us. Jean Antoine Petit-Senn (1792–1870) was a thorough Genevese and a biting satirist, a pensive poet, the "Genevese La Bruyère," as he liked to be called, but was not fully appreciated till after his death, when his widely scattered writings were brought together. Alexandre Vinet (*q.v.*), the theologian, and H. F. Amiel (*q.v.*), the philosopher, in a fashion balance each other, and need only be mentioned here. Jean Jacques Porchat (1800–1864) was one of the most prominent among the minor poets of the region, very French owing to his long residence in Paris, and best remembered probably by his fables, first published in 1837 under the title of *Glanures d'Esope* (reissued in 1854 as *Fables et paraboles*), though in his day his stories for the young were much appreciated. Urbain Olivier (1810–1888), a younger brother of the poet, wrote many tales of rural life in Vaud, while the Genevese novelist Victor Cherbuliez (1829–1899, *q.v.*) was perhaps the most brilliant of a brilliant family. Fribourg has produced the local novelist Pierre Sciobéret (1830–1876) and the Bohemian poet Étienne Eggis (1830–1867), and Neuchâtel Auguste Bachelin (1830–1890) whose best novel was *Jean Louis*, a tale of which the scene is laid in the old-fashioned little village of St Blaise. Another Neuchâtel writer, Alice de Chambrier, the poetess, died young, as did the Genevese poet Louis Duchosal, both showing in their short lives more promise than performance. Madame de Gasparin's (1813–1894) best tale is *Horizons prochains* (1857), a very vivid story of rural life in the Vaudois Jura, remarkable for the virile imagination of its descriptions.

Edouard Rod (*q.v.*) the novelist, and Marc Monnier (*q.v.*), critic, poet, dramatist and novelist, are the most prominent figures in the recent literature of the Suisse Romande. Amongst lesser stars we may mention in the department of belles-lettres (novelists, poets or critics) Charles Du Bois-Melly, "T. Combe" (the pen name of Mlle Adèle Huguenin), Samuel Cornut, Louis Favre, Philippe Godet, Oscar Huguenin, Philippe Monnier, Noëlle Roger, Virgile Rossel, Paul Seippel and Gaspard Vallette. The chief literary organ of the Suisse Romande is the *Bibliothèque universelle*, which in 1816 took that title in lieu of *Bibliothèque britannique* (founded in 1796), and in 1861 added that of *Revue suisse*, which it then absorbed. Amongst historians the first place is due to one of the most learned men whom Switzerland has ever produced, and whose services to the history of the Valais were very great, and abbé Jean Gremaud (1823–1897) of Fribourg. The principal contemporary historians are Victor van Berchem, Francis De Crue, Camille Favre, Henri Fazy, B. de Mandrot, Berthold van Muyden and Édouard Rott.

c. Italian Branch.—Italian Switzerland is best known by its artists, while its literature is naturally subject to strong Italian influences, and not to any of a strictly Swiss nature. Stefano Franscini (1796–1857) did much for his native land, especially in educational matters, while his chief published work (1835) was one that gave a general account of the canton. But this is not so thorough and good as a later book by Luigi Lavizzari (1814–1875), entitled *Escursioni nel cantone Ticino* (1863), which is very complete from all points of view. Angelo Baroffio (d. 1893) and Emilio

Motta represent the historical sciences, the latter contributing much to the *Bollettino della Svizzera Italiana* (from 1879 onwards), which, though mainly historical, devotes much space to literary and historical matters relating to the canton. The art of novel writing does not flourish in Ticino. But it has produced a great number of poets such as Pietro Peri (1794–1869), who translated the Swiss national anthem into Italian, J. B. Buzzi (1825–1898), Giovanni Airoldi (died before 1900) and Carlo Cioccari (1829–1891)—the two former were lyric poets, and the third a dramatist. Two younger singers are F. Chiesa and M. A. Nessi.

d. Romonsch and Ladin Branch.—In the Grisons alone still lingers a quaint Romance dialect, which is a laggard sister of French and Italian, and has therefore not much to show in the way of literary activity. Indeed it would probably have perished altogether by this time had not certain energetic men and societies more or less successfully tried to bring about a sort of artificial revival. It is distinguished into two main dialects, that of the Bündner Oberland or the valley of the Vorder Rhine being called Romonsch, while that spoken in the Engadine and the neighbouring valleys is known as Ladin. Both took their origin from the spoken tongue or lingua rustica Romana in the days of the later empire. The earliest known monument of this interesting survival was discovered in 1907, and consists of a few lines, in an early form of the Romonsch dialect, of interlinear translation (with the original Latin text) of a sermon attributed to St Augustine. This monument is said to date from the early 12th century. The first poem in Ladin was one on the Musso War, written in 1527 by Johann von Travers (1483–1563), though it was not published till 1865. The first book printed in it (at Poschiavo in 1552) was the translation of a German catechism, and the next a translation of the New Testament, also at Poschiavo, but in 1560. Most of the works in both these dialects are translations of books of a religious or educational nature. The principal writers in the Romonsch dialect (the less literary of the two) of recent times are Theodor von Castelberg (1748–1830), a poet and translator of poetry, and P. A. de Latour (about 1814) also a poet, while the best of all poets in this dialect was Anton Huonder, whose lyrics are considered remarkable. Alexander Balletta (1842–1887) wrote prose romances and sketches, while J. C. Muoth (1844–1906), himself a most typical and characteristic figure, wrote much in prose and verse as regards his native region. In Ladin one of the chief figures was the poet Conradin von Flugi (1787–1874), who published volumes of poems in 1845 and 1861, but the poems, novels and translations of J. F. Caderas (1830–1891) are placed above them. Other Ladin poets are Florin Valentin, O. P. Juvalta and S. Caratsch (d. 1892), while P. Lansel represents a younger generation. Zaccaria Pallioppi (1820–1873) also wrote poems, but the excellent Ladin dictionary that he compiled was not published till 1895 by the care of his son. (W. A. B. C.)

BIBLIOGRAPHY.—*a. General.*—The indispensable work for any one desiring to know what books have been written on any subject relating to Switzerland is the officially published *Bibliographie der schweizerischen Landeskunde*, a series of detached parts, each complete in itself, and issued separately (Bern, from 1892 onwards). In particular may be mentioned: A. Wäber's *Landes- und Reisebeschreibungen* (1899; with a supplement, 1909), that deals with works of travel in Switzerland (see, too, the new edition, London, 1899, of J. Ball's *Hints and Notes for Travellers in the Alps*, pp. 140–152), and J. H. Graf, *Kartenwesen* (1896), which enumerates all the maps of Switzerland and its various districts. Among the best of the older descriptions may be mentioned those of A. von Bonstetten (1479), Conrad Türst (1495), Sebastian Münster (1544), J. Stumpf (1548), J. Simler (1574), M. Merian (1642), J. J. Scheuchzer (1723), G. S. Gruner (1760), P. F. D. de Zurlauben (1777) and W. Coxe (1779). More modern, but still useful in many ways, are Max Wirth, *Allgemeine Beschreibung und Statistik der Schweiz* (3 vols., Zürich, 1871–1875), and H. A. Berlepsch, *Schweizerkunde* (2nd ed., Brunswick, 1875). The most complete and recent monograph on the country from all points of view is the work (700 pp.) entitled *La Suisse* (also in German), with atlas of 48 maps, reprinted from the *Dictionnaire géographique de la Suisse* (Neuchâtel, 1909). For a pretty complete detailed account of its chief towns, villages and mountains, by far the best work is the *Dictionnaire géographique de la Suisse* (Neuchâtel, 1902, and following years; it is also issued in German). A complete account of the country in the 19th century is given in the work entitled *La Suisse au xix^{me} siècle* (3 vols., Lausanne, 1899–1900; also issued in German). For statistics see the official census of 1900 (Bern, 3 vols., 1904–1907), as well as the annual official publication *Statistisches Jahrbuch der Schweiz* (from 1891, see specially the vol. for 1897, *Atlas graphique et statistique de la Suisse*, with many diagrams), and another (appearing six times a year at Bern, since 1865) the *Zeitschrift für schweizerische Statistik*. For educational matters the annual official *Jahrbuch für Unterrichtswesen in der Schweiz* (Zürich, from 1894) is very useful. For mountaineers there is the Climbers' Guides Series (London, from 1890, now comprising 11 vols. relating to Switzerland), and the two works published by the Swiss Alpine Club, *Clubführer durch die Glarner Alpen* (1902), and *Clubführer durch die Urner Alpen* (2 vols., 1905). Murray's *Handbook for Travellers in Switzerland* was thoroughly revised (19th edition) in 1904, while it is not necessary to do more than mention the guide-books of Bäedeker and Joanne, of which new editions often appear (that by Iwan von Tschudi is no longer kept up to date).

The best *maps* of Switzerland are those published by the Federal Topographical Bureau at Bern. One, called from the director of the survey (G. H. Dufour, 1787–1875) the *Dufour Map* (scale 1 : 100,000), was published in twenty-five sheets between 1845 and 1863 (see the detailed history of this map in the work entitled *Die schweizerische Landesvermessung, 1832–1864*, Bern, 1896). It has however, been practically superseded by the issue (revised and corrected) of the original survey (scale 1 : 25,000 for the plains and 1 : 50,000 for the mountain districts) in 598 sheets, of which the publication began in 1870—this magnificent map, one of the finest ever executed, is named the *Siegfried Atlas*, from the successor of Dufour at the head of the survey, Hermann Siegfried (1819–1879). The history of Swiss travel has been told by G. Peyer, *Geschichte des Reisens in der Schweiz* (Basel, 1885), and W. A. B. Coolidge, *Swiss Travel and Swiss Guide-Books* (London, 1889). That of the exploration of the Swiss Alps is contained in Gottlieb Studer's *Über Eis und Schnee* (Bern, 3 vols., new ed., 1896–1899), while Bernard Studer's *Geschichte der physischen Geographie der Schweiz bis 1815* (Bern, 1863) describes the gradual examination of the country from the scientific point of view. The last-named work contains many short lives of eminent Swiss. These are narrated more in detail in R. Wolf's *Biographieen zur Kulturgeschichte der Schweiz* (4 vols., Zürich, 1858–1862); E. Secretan's *Galerie suisse* (3 vols., Lausanne, 1873–1880); and *Sammlung berner Biographieen* (Bern, as yet 5 vols., 1884–1906). (See also ALPS and GLACIERS.)

As to *languages* in Switzerland the best general work is J. Zimmerli's *Die deutsch-französische Sprachgrenze in der Schweiz* (3 vols., Basel and Geneva, 1891–1899); while for the Swiss-German dialects there is the splendid *Schweizerisches Idiotikon* (of which the publication began at Frauenfeld in 1881); and the *Glossaire des patois de la Suisse romande*. For one branch of the curious Ladin dialect, see Z. and E. Pallioppi's *Dizionari dels idioms romauntschs d'Engiadina*, &c. (Samaden, 1895); while for select extracts of all branches of the Romonsch or Ladin literature consult C. Decurtins, *Rätoromanische Chrestomathie* (8 vols., Erlangen, 1894–1907), of which the vols. i., ii., iii. and iv. refer to the Romonsch dialect of the Bündner Oberland, and the rest to the Ladin dialect of the Engadine. F. J. Stalder's *Versuch eines schweizerischen Idiotikon* (2 vols.- Aarau, 1806–1812) is still useful, as is his later work *Die Landessprachen der Schweiz* (Aarau, 1819).

The *Archiv für Volkskunde* published by the *Société suisse des traditions populaires* (Zürich, from 1897), contains much that is interesting in the way of folk-lore, while for Swiss legends in general consult E. Kohlrusch, *Schweizerisches Sagenbuch* (Leipzig, 1854); A. Lütolf, *Sagen, Bräuche, Legenden aus den Fünf Orten* (Lucerne, 1862); M. Tscheinen and P. J. Ruppen, *Walliser-Sagen* (Sion, 1872); A. Cérésole, *Légendes des alpes vaudoises* (Lausanne, 1885); J. Kuoni, *Sagen des Kantons St Gallen* (St Gall, 1903); T. Vernaleken, *Alpensagen* (Vienna, 1858); D. Gempeler's *Sagen und Sagengeschichten aus dem Simmenthal* (Thun, 1883–1893); and *Walliser-Sagen* (2 vols., Brieg, 1907). Another feature of the life of the people in Switzerland is treated in H. Herzog's *Schweizerische Volksfeste, Sitten, und Gebräuche* (Aarau, 1884).

For *educational* matters the two following books (with the *Jahrbuch für Unterrichtswesen in der Schweiz*, already mentioned) will be found specially useful: F. Escali, *L'Instruction primaire en Suisse* (Paris, 1883) and the annual volume (Geneva, from 1904) entitled *L'Education en Suisse*. For the Swiss universities see the special histories mentioned in the articles on the several cantons, while for the Swiss Polytechnic School at Zürich, consult W. Oechsli's *Geschichte der Gründung des eidg. Polytechnicums* (Frauenfeld. 1905).

As to the *mountain pastures*, see ALP, where a list of books is given.

Swiss *carriage roads*, especially across the Alpine passes, are described in S. Bavier, *Die Strassen der Schweiz* (Zürich, 1878), and the official book, *Die schweizerischen Alpenpässe* (2nd ed., 1893). For the history of the several Swiss Alpine passes consult in particular P. H. Scheffel, *Verkehrsgeschichte der Alpen* (Berlin, 1908–1909); R. Reinhard, *Pässe und Strassen in den schweizer Alpen* (Lucerne, 1903), which gives full references; and E. Oehlmann's articles "Die Alpenpässe im Mittelalter," published in vols. iii. and iv. (Zurich, 1878–1879) of the *Jahrbuch für schweizerische Geschichte*). The Simplon has a special history, F. Barbey, *La Route du Simplon* (Geneva, 1906), as has also the St Gotthard; E. Motta, *Dei Personaggi celebri che varcarono il Gottardo nei tempi antichi e moderni* (Bellinzona, 1884; later continued in the *Bollettino della Svizzera Italiana*). As to Swiss *railways* in general, see R. Herold, *Der schweizerische Bund und die Eisenbahnen bis zur Jahrhundertwende* (Munich, 1902); P. Weissenbach, *Die Eisenbahnverstaatlichung in der Schweiz* (Berlin, 1905); and C. P. Wiedemann, *Die geschichtliche Entwicklung der schweizer. Eisenbahngesetzgebung* (Zürich, 1905). The St Gotthard railway and its history are treated of at length by M. Wanner in his two works—*Geschichte der Begründung des Gotthardunternehmens* (Lucerne, 1880); and

Geschichte des Baues der Gotthardbahn (Lucerne, 1885). For a general estimate of the commercial importance of the Simplon railway, see A. Möhring, *Die Simplonbahn—eine verkehrswirthschaftliche Studie* (Bern, 1907). For a technical description of the works for the Simplon tunnel see an article (also issued separately) by K. Pressel in vol. xlvii. of the *Schweizerische Bauzeitung* (Zürich), while similar details, as well as more general notices, relating to the Splügen tunnel are given in G. Bener and R. Herold, *Studien zur Ostalpenbahnfrage* (Zürich, 1907); and A. Mettler, *Der Splügen als ostschweizerische Alpenbahn* (Zürich, 1907). As to the Jungfrau railway, see A. H. Guyer-Zeller, *Das Projekt der Jungfraubahn* (Zürich, 1896, with atlas of plates); and S. Herzog, *Die Jungfraubahn* (Zürich, 1904). A special part of the *Bibliographie der schweizer. Landeskunde* is devoted to Swiss railways.

Economical: Trade and Commerce.—As to the general economical state of Switzerland, the older *Volkswirthschafts-Lexikon der Schweiz*, by A. Furrer (Bern, 4 vols., 1885–1892), may still be consulted with advantage, while naturally more up to date is N. Reichesberg's *Handwörterbuch der Schweiz. Volkswirthschaft, Socialpolitik und Verwaltung* (Bern, since 1903). A very useful and well-arranged work is A. Le Cointe's *Inventaire des institutions économiques et sociales de la Suisse à la fin du xix^{me} siècle* (Geneva, 1900). W. H. Dawson's *Social Switzerland* (London, 1897), deals with matters rather from the social than from the strictly economical standpoint, but contains a variety of interesting information, while H. D. Lloyd's *The Swiss Democracy* (London, 1908), is rather more political. A very handy, trustworthy and admirable work of moderate size on Switzerland generally from an economical point of view is T. Geering and R. Hotz's *Économie politique de la Suisse* (Zürich, 1903, trans. of a German work issued in 1902)—the German only has the detailed bibliography. P. Clerget's *La Suisse au xx^{ème} siècle* (Paris, 1908), is very useful. Other works relating to Swiss industries and commerce are T. Geering, *Die Handelspolitik der Schweiz am Ausgang des xix. Jahrhunderts* (Berlin, 1902); E. Hofmann, *Die Schweiz als Industriestaat* (Zürich, 1902); and H. Wartmann, *Industrie und Handel der Schweiz im xix. Jahrhundert* (Bern, 1902). The following are historical monographs as to some of the principal Swiss industries: A. Bürkli-Meyer, *Die Geschichte der zürcherischen Seidenindustrie* (Zürich, 1894); H. Lehmann, *Die aargauische Strohindustrie* (Aarau, 1896); and A. Steinmann, *Die ostschweizerische Stickerei-Industrie* (Zürich, 1905); while the following deal rather with local centres of industry: H. Wartmann, *Industrie und Handel des Kantons St Gallen auf 1866* (St Gall, 1870, besides many reports as to local industry, 1708 to 1890); T. Geering, *Handel und Industrie der Stadt Basel* (Basel, 1886); A. Bachelin, *L'Horlogerie neuchâteloise* (Neuchâtel, 1888); and A. Pfleghart, *Die schweizerische Uhrenindustrie* (Leipzig, 1908). A full technical and well-illustrated description of some of the chief industrial establishments in Switzerland is given in *Die industrielle und kommerzielle Schweiz beim Eintritt ins xx. Jahrhundert* (Zürich, since 1900); while B. de Cérenville's *Le Système continental et la Suisse, 1803–1813* (Lausanne, 1906) treats of an interesting period in Swiss commercial history. Swiss mercantile law is expounded in A. Curti's *Schweizerisches Handelsrecht* (Zürich, 1903). For purely financial matters the *Finanz Jahrbuch* (Bern, from 1899), contains much information of the latest date; while H. Ernst's *Eine schweizerische Bundesbank* (Winterthur, 1904) sketches the foundation of the Swiss National Bank that was successfully launched in 1907. G. Schanz's *Die Steuern der Schweiz* (5 vols., Stuttgart, 1890) is a remarkably complete and instructive work; while the later book by J. Steiger, *Grundzüge des Finanzhaushaltes der Kantone und Gemeinden* (2 vols., Bern, 1903), is specially devoted to taxes levied by the cantons and the communes, and is of the greatest utility in studying a very complicated subject. E. Naef's *Tabakmonopol und Biersteuer* (Zürich, 1903), treats of two special sources of revenue in the Swiss financial system. The history of the Swiss coinage is admirably narrated, with many fine illustrations, by L. Coraggioni, in his *Münzgeschichte der Schweiz* (Geneva, 1896), and is the chief authority on Swiss numismatics in general.

As to the *fine arts*, the best general work on medieval Swiss architecture is J. R. Rahn's *Geschichte der bildenden Künste in der Schweiz* (Zürich, 1876). The same author has also collected various of his art essays in his *Kunst- und Wanderstudien in der Schweiz* (Vienna, 1883), while he has described (alone or with the help of others) the chief art monuments in the various Swiss cantons—these notices appeared in the *Anzeiger für schweiz. Alterthumskunde* (Zürich, from 1868), and for the cantons of Soleure, Ticino, Thurgau and Unterwalden, form appendices which are really art monographs. An older and more special work on the same subject is J. D. Blavignac's *Histoire de l'architecture sacrée du iv^{me} au x^{me} siècle dans les anciens évêchés de Genève, Lausanne, et Sion* (Geneva, 1853). There are two general books on the special subject of Swiss castles—Mme de Montmolier's *Les Châteaux suisses* (1816–1823, new ed., later); and F. Küpfer's *Burgen und Schlösser der Schweiz* (n.d.). Many have now special monographs; so *Habsburg* (1896) and *Lenzburg* (1904), both by W. Merz, whose later work *Die mittelälterlichen Burganlagen und Wehrbauten des Kantons Aargau* (2 vols., Aarau, 1906) is a very complete treatise on the most castellated region of the country. For the Bernese castles we have E. L. C. Eden and A. von Fischer's *Die Schlösser d. Kant. Bern* (Bern, about 1898). All the great churches of Switzerland have also been made the subject of monographs—so the Münster in Bern, by B. Haendcke and V. Muller (Bern, 1894); Lausanne, by E. Dupraz (Lausanne, 1906), &c. As to the wooden architecture so characteristic of Switzerland, consult E. G. Gladbach's *Die Holz-Architektur der Schweiz* (2nd ed., Leipzig, 1885—the same author has also issued several series of plates illustrating this subject). Domestic Swiss architecture in general is represented by J. Hunziker's *Das Schweizerhaus* (Aarau), which includes 4 vols. dealing respectively with the Valais (1900), Ticino (1902), the Grisons and Glarus (1905), and the Jura with most of the Suisse Romande (1907). A. Robida's *Les Vieilles villes de Suisse* (Paris, 1879) is a pleasantly written book. The biographies of Swiss artists are conveniently summarized in the *Schweizerisches Künstler-Lexikon* (Frauenfeld, from 1902 onwards), the order followed being alphabetical, while full references to special works, are given in each case. For Swiss glass painting, see H. Meyer's *Die schweizerische Sitte der Fenster- und Wappenschenkung vom xv. bis xvii. Jahrhundert* (Frauenfeld, 1884); and B. Haendcke's *Die schweiz. Malerei im xvi. Jahrhundert unter Berücksichtigung der Glasmalerei, des Formschnittes, und des Kupferstiches* (Aarau, 1893); while Swiss fresco painting is treated of in Konrad Escher's *Untersuchungen zur Geschichte der Wand- und Deckenmalerei in der Schweiz vom ix. bis zum Anfang des xvi. Jahrhunderts* (Strassburg, 1906); while the town shields are depicted in P. Küpfer's *Armorial des villes suisses* (Basel, 1885); and their seals in E. Schulthess's *Die Städte- und Landes-Siegel der Schweiz* (Zürich, 1853). Early Swiss heraldry is historically described in P. Ganz's *Geschichte d. herald. Kunst in der Schweiz im xii. und xiii. Jahrhundert* (Frauenfeld, 1899). The Swiss Renaissance is dealt with by G. Schneeli, *Renaissance in der Schweiz* (Munich, 1896); while J. H. Heer in his *Die schweiz. Malerei des xix. Jahrhunderts* (Leipzig, 1905), has printed his lectures relating to most of the best-known modern Swiss painters. Many splendid series of reproductions in various departments of Swiss art have appeared, two of the most striking being the three series of *Handzeichnungen schweizerischer Meister des xv.–xviii. Jahrhunderts* (Basel, from 1904); and the *Kunstdenkmäler der Schweiz* (2nd series, Geneva, from 1901), to which we may add R. Anheisser's *Altschweizerische Baukunst* (Bern, 1906–1907); R. Hinderer, *Alte schweizer Bauweise* (Frankfort, 1907); and the four series (Bern, 1883–1887) of E. von Rodt's *Kunstgeschichtliche Denkmäler der Schweiz.* The most artistic and accurate reproductions of Swiss costumes are the thirty-six coloured plates, drawn after originals, published by Fr. Julie Heierli (Zürich, 1897, sqq.), under the title of *Die schweizer Trachten vom xvii.–xix. Jahrhundert.*

b. History.—The great collection (officially published in 32 vols., 1858–1905) entitled *Amtliche Sammlung der ältern eidgenössischen Abschiede* contains all the recesses of the Diet, &c., from 1245 to 1848, and is absolutely indispensable. A series of selected extracts from chroniclers, documents, &c., is given in W. Oechsli's *Quellenbuch zur Schweizergeschichte* (2 vols. 2nd ed. of vol. i. 1901, and 1st ed. of vol. ii., Zürich, 1893). The texts (with short introductions) of all the Federal Constitutions from 1798 onwards are conveniently collected in S. Kaiser and J. Strickler's *Geschichte und Texte der Bundesverfassungen der schweiz. Eidgenossenschaft von 1798 bis zur Gegenwart* (Bern, 1901). The texts of the early alliances (1291–1513) are reprinted in J. von Ah's *Die Bundesbriefe der alten Eidgenossen* (Einsiedeln, 1891), while a commentary on all the Federal Constitutions from 1291 (with reprints of certain texts) is furnished by C. Hilty in his *Die Bundesverfassungen der schweiz. Eidgenossenschaft* (Bern, 1891; also in French). For more recent documents and laws see the *Amtliche Sammlung der Bundesgesetze* (from 1849 onwards), which are conveniently arranged and classified by P. Wolf in his *Die schweizerische Bundesgesetzgebung* (2nd ed., 3 vols., Basel, 1905–1908). G. von Wyss's *Geschichte der Historiographie in der Schweiz* (Zürich, 1895) is an admirable guide to the works and lives of all Swiss historians up to about 1850, while all articles (published in Swiss periodicals from 1812 to 1900) relating to the subject are most carefully indexed and classified in J. L. Brandstetter and H. Barth's *Repertorium über die in Zeit- und Sammelschriften enthaltenen Aufsätze und Mitteilungen schweizergeschichtlichen Inhaltes* (2 vols., Basel, 1892 and 1906).

The latest revised texts of the Federal Constitution and (often) of the cantonal constitutions can be procured separately, but the last official collection of all in one volume dates from 1891 (*Recueil des constitutions fédérales et cantonales*), since which time many changes have been made. These can generally be discovered, and much valuable present-day knowledge of Swiss matters gained, in C. Hilty's *Politisches Jahrbuch der schweizer. Eidgenossenschaft* (published at Bern annually since 1886).

The best general recent histories are J. Dierauer, *Geschichte der schweizerischen Eidgenossenschaft* (3 vols., up to 1648, Zürich, 1887–1907 to be continued), which gives in detail the original authorities and the statements of modern writers for every point; W. D. McCrackan, *The Rise of the Swiss Republic* (2nd ed., New York, 1901), and B. van Muyden, *Histoire de la nation suisse* (3 vols., Lausanne, 1896–1899). Some of the older histories (such as those of Daguet and Dändliker) may still be consulted with advantage, while W. Oechsli's

Lehrbuch für den Geschichtsunterricht in der Sekundärschule (Zürich, 1885), is very accurate and handy. Far more popular in style than any yet mentioned are J. Sutz's *Schweizer-Geschichte für das Volk erzählt* (La Chaux de Fonds, 1899), and A. Gobat, *Histoire de la Suisse racontée au peuple* (Neuchâtel, 1900). A very attractive summary (including social and economical history) is given in H. Vulliéty's *La Suisse à travers les âges* (Basel and Geneva, 1901).

J. Heierli's *Urgeschichte der Schweiz* (Zürich, 1901) has superseded all earlier works (such as Heer) on prehistoric Switzerland. The authentic early history of the Confederation (see also TELL, TSCHUDI, and WINKELRIED) is admirably told in W. Oechsli's *Die Anfänge der schweizerischen Eidgenossenschaft* (Zürich, 1891, also in French), as well as in the older work by A. Rilliet, *Les Origines de la confédération suisse* (2nd ed., Geneva and Basel, 1869). For the earlier medieval history (1273–1334) J. E. Kopp's *Geschichte der eidgenössischen Bünde* (5 vols., Leipzig, Lucerne and Basel, 1845–1882) is a perfect storehouse of information, while the medieval political Swiss system in relation to the empire has been very clearly described by W. Oechsli in his article (published in vol. v., 1890, of Hilty's *Politisches Jahrbuch*) "Die Beziehungen der schweiz. Eidgenossenschaft zum Reiche bis zum Schwabenkrieg, 1499," while the same writer's article (published in vol. xiii., 1888, of the *Jahrbuch für schweizerische Geschichte*) "Orte und Zugewandte," gives an admirable account of the relations of many small districts and towns to the Swiss Confederation, as "allies," from the earliest times to 1798. The two following works trace certain phenomena throughout Swiss history —P. Schweizer, *Geschichte der schweizerischen Neutralität* (Frauenfeld, 1895), and J. Schollenberger, *Geschichte der schweizer. Politik* (2 vols., Frauenfeld, 1906 and 1908). As to the more recent history of Switzerland (since 1798) see, besides various articles in Hilty's *Jahrbuch*, C. Hilty, *Öffentliche Vorlesungen über die Helvetik* (Bern, 1878); W. Oechsli, *Geschichte der Schweiz im xix. Jahrhundert* (vol. i., Leipzig, 1903, extends from 1798 to 1813); F. Burckhardt, *Die schweizerische Emigration, 1798–1901* (Basel, 1908); B. van Muyden, *La Suisse sous le pacte de 1815* (2 vols., 1815–1838, Lausanne, 1890–1891); G. H. Dufour, *Der Sonderbunds-Krieg und die Ereignisse von 1856 in Neuenburg* (Basel, 1876; also in French, Paris, 1876); G. Grote, *Seven Letters concerning the Politics of Switzerland* (1847, enlarged ed., London, 1876); T. Curti, *Die schweizerischen Volksrechte, 1848–1900* (Bern, 1900); J. Schollenberger, *Die Schweiz seit 1848* (Berlin, 1908); and the blue-book (London, 1848) entitled *Correspondence Relative to the Affairs of Switzerland*, with the following volumes of memoirs by Swiss statesmen: A. P. Segesser, *Fünf und vierzig Jahre im luzernischen Staatsdienst, 1841–1887* (Bern, 1887); J. C. Kern, *Souvenirs politiques, 1838–1883* (Bern, 1887); and Numa Droz, *Études et portraits politiques* (Geneva, 1895), as well as lives of others. For the history of Switzerland in the 19th century see T. Curti, *Geschichte der Schweiz im xix. Jahrhundert* (Neuchâtel, 1902), and the work entitled *La Suisse au xix^me siècle* (3 vols., Lausanne, 1899–1900; also issued in German).

The following works are very useful for various departments of Swiss history: *Genealogisches Handbuch zur schweizer Geschichte* (in course of publication since 1900 at Zürich); P. Ganz, *Geschichte der heraldischen Kunst in der Schweiz im xii. and xiii. Jahrhundert* (Frauenfeld, 1899); E. Schulthess, *Die Städte- und Landes-Siegel der Schweiz* (Zürich, 1853); P. Küpfer's *Armorial des villes suisses* (120 shields, Basel, 1885); A. Gautier, *Les Armoiries et les couleurs de la confédération et des cantons suisses* (2nd ed., Geneva and Basel, 1879); and L. Tobler's *Schweizerische Volkslieder* (2 vols., Frauenfeld, 1882–1884; many historical ballads, texts with introductions). The best historical atlas is the *Historisch-geographischer Atlas der Schweiz* by J. C. Vögelin, G. Meyer von Knonau and G. von Wyss (new ed., Zürich, 1870), while L. Poirier-Delay and F. Müllhaupt's *Historischer Atlas der Schweiz* (Bern, 1898), and J. S. Gerster's small maps (Zürich, 1886) are also useful. There is a set of small Swiss historical maps in one sheet (No. 25) in Droysen's *Allgemeiner historischer Atlas* (Bielefeld, 1886), and a single general one (No. 44) in R. L. Poole's *Historical Atlas of Modern Europe* (Oxford, 1902).

For the pre-1798 constitution of Switzerland see J. Simler, *De Helvetiae republicâ* (Zürich 1576; also in German and French), and Abraham Stanyan's *An Account of Switzerland* (London, 1714).

The best and most recent works on the existing Swiss constitution of 1874 and its history are the large volume by W. Burckhardt, *Kommentar der schweiz. Bundesverfassung von 1874* (Bern, 1905), and the smaller one by J. Schollenberger, *Bundesverfassung der Schweiz. Eidgenossenschaft. Kommentar mit Einleitung* (Berlin, 1905), while the same author's *Das Bundesstaatsrecht der schweiz. Geschichte und System* (Berlin, 1902) and his *Grundriss der Staats- und Verwaltungsrechts der schweiz. Kantone* (2 vols., Zürich, 1898–1899) are clear, and, especially the last-named, very useful as to cantonal matters. In English there is nothing better than J. M. Vincent's *Government in Switzerland* (New York and London, 1900), for the work by F. O. Adams and C. D. Cunningham is not very satisfactory, though better in its French edition (Basel and Geneva, 1890) than in its original English shape (London, 1889). The decisions of the Swiss Federal Tribunal as to Swiss constitutional law are collected (up to the end of 1902) in L. R. von Salis's *Schweizerisches Bundesrecht* (2nd ed., 5 vols., Bern, 1903–1904), while H. Ryffel's *Die schweizer. Landsgemeinden* (Zürich, 1904) and T. Curti's *Die schweizer. Volksrechte* (Bern, 1900) touch on special sides of the subject. See, too, COMMUNE (Swiss) and REFERENDUM AND INITIATIVE. Many of the older works are still worth consulting, such as those by Snell (1839–1844), Stettler (1847), Ullmer (1862–1866), Pfaff (1870), Bluntschli (2nd ed., 1875), Meyer (1875–1878), Dubs (1878), Orelli (1885), and Blumer (latest ed., vol. i., 1891; vols. ii. and iii., 1880–1887). There are also useful articles in Furrer's and Reichesberg's dictionaries. J. J. Blumer's *Staats- und Rechtsgeschichte der schweiz. Demokratieen* (2 vols., St Gall, 1850–1858) deals collectively with the old democratic cantons—Uri, Schwyz, Unterwalden, Glarus, Zug and Appenzell—and is still very useful for local history; the special works as to the constitutional history of other cantons are mentioned in the articles relating to them. A general theoretical work on federal constitutions in general is L. le Fur's *État Fédéral et Confédération d'états* (Paris, 1896), vol. i. of a new German edition of which (prepared by the author with the help of P. Posener) appeared at Breslau in 1902; this is more up to date than E. A. Freeman's *Federal Government* (new ed. of vol. i., London, 1893), or than J. B. Westerkamp's *Staatenbund und Bundesstaat* (Leipzig, 1900).

There is no really satisfactory general ecclesiastical history of Switzerland before the Reformation, though monographs abound, and much material has been collected in the *Zeitschrift für Schweizerische Kirchengeschichte* (Stans, from 1907). E. E. Gelpke's *Kirchengeschichte der Schweiz* (2 vols., Bern, 1856–1861) is now out of date, and only includes the early portion of the period (it is written from a Protestant standpoint), while vol. ii. of B. Fleischlin's *Studien und Beiträge zur schweizer. Kirchengeschichte* (Lucerne, 1902–1903) includes the period 800 to 1520, but is written from a strong Romanist point of view. As to the early history consult E. Egli's *Die christlichen Inschriften der Schweiz von iv–ix. Jahrhundert* (Zürich, 1895), and his *Kirchengeschichte der Schweiz bis auf Karl den Grossen* (Zürich, 1893); S. Guyer, *Die christlichen Denkmäler des ersten Jahrtausends in der Schweiz* (Leipzig, 1907); A. Lütolf, *Die Glaubensboten der Schweiz vor St Gallus* (Lucerne, 1871); and E. F. Gelpke, *Die christliche Sagengeschichte der Schweiz* (Bern, 1862). As to the medieval saints in Switzerland see E. A. Stückelberg, *Geschichte der Reliquien in der Schweiz* (2 vols., Zürich and Basel, 1902 and 1908), and his *Die schweiz. Heiligen des Mittelalters* (Zürich, 1903), and J. Genoud's *Les Saints de la Suisse française* (new ed., 2 vols., Fribourg, 1897). For the documentary history of some of the medieval Swiss dioceses see *Regesta episcoporum constantiensium*, edited by P. Ladewig and T. Müller (2 vols., from 596 to 1383, as yet published, Innsbruck, 1895 and 1905); M. Besson, *Recherches sur les origines des évêchés de Genève, Lausanne, et Sion* (Fribourg, 1906), and L. Stouff, *Le Pouvoir temporal des évêques de Bâle* (2 vols., Paris, 1891). E. E. von Mülinen's *Helvetia sacra* (2 vols., Bern, 1858 and 1861) gives the succession of the various bishops, abbots, provosts, &c., but requires bringing up to date. For the medieval Swiss monasteries we have *Die Regesten der Archive in der schweiz. Eidgenossenschaft* (edited by T. von Mohr; 2 vols., Coire, 1851–1854), though it refers only to a few monasteries, for which it is indispensable, while Arnold Nüscheler's *Die Gotteshäuser der Schweiz* (3 pts., Zürich, 1864–1873, continued by the author and others in the *Geschichtsfreund* and *Argovia*, complete index issued as an appendix to the *Anzeiger für schweizerische Geschichte*, 1900) is most valuable and useful. Some of the great monasteries have histories of their own, such as Einsiedeln (*q.v.*), Engelberg (*q.v.*), and Muri, the last by Pater M. Kiem, *Geschichte der Benedictiner-Abtei Muri* (2 vols., Stans, 1888 and 1891). Two monographs may be mentioned: R. G. Bindschedler, *Kirchliches Asylrecht und Freistätten in der Schweiz* (Stuttgart, 1906), and Augusta Steinberg, *Studien zur Geschichte der Juden in der Schweiz während des Mittelalters* (Zürich, 1903). For the Reformation and later times consult (on the Protestant side), besides biographies, &c., of Calvin and Zwingli (*qq. v.*), E. Bloesch, *Geschichte der schweizerisch-reformierten Kirchen* (2 vols., Bern, 1898–1899); and W. Hadorn, *Geschichte des Pietismus in der schweiz. reform. Kirchen* (Constance, 1901), and the same author's *Kirchengeschichte der reformierten Schweiz* (since 1906). F. Meyer's work, *Die evangelische Gemeinde in Locarno* (2 vols., Zürich, 1836), treats of an important event of that period. The Romanist standpoint is presented in vols. iii. and iv. (1904 sqq.) of Fleischlin's work mentioned above, and also in J. G. Mayer's *Das Conzil von Trient und die Gegenreformation in der Schweiz* (2 vols., Stans, 1901 and 1903).

For more modern days the best book, especially from the constitutional side, is C. Gareis and P. Zorn, *Staat und Kirche in der Schweiz* (2 vols., Zürich, 1877–1878), which tells the story down to the date of publication. Special subjects are treated of in M. Kothing, *Die Bisthumsverhandlungen der schweizerisch-konstanzischen Diözesanstände von 1803–1862* (Schwyz, 1863); F. Troxler, *Der Kulturkampf von 1863–1888* (Bienne, 1889); Ch. Woeste, *Histoire du Culturkampf en Suisse, 1871–1886* (Brussels, 1887, Romanist work); and P. Gschwind, *Geschichte der Entstehung der christkatholischen Kirche der Schweiz* (vol. i. appeared at Basel in 1904). The work by A. Büchi entitled *Die katholische Kirche in der Schweiz* (Munich, 1902) gives a full and authorized account of the present state of the Roman Catholic Church in Switzerland.

c. Literature.—For the Swiss medieval Minnesingers see Karl Bartsch, *Die schweizer Minnesänger* (Frauenfeld, 1887, texts, with introductions); and for popular ballads, historical or not, L. Tobler, *Schweizerische Volkslieder* (2 vols., Frauenfeld, 1882–1884, texts, with notes and introductions). In general consult J. Bächtold, *Geschichte der deutschen Literatur in der Schweiz* (Frauenfeld, 1892); E. H. Gaullieur, *Études sur l'histoire littéraire de la Suisse française, particulièrement dans la seconde moitié du xviii^me siècle* (Paris, 1856); P. Godet, *Histoire littéraire de la Suisse romande* (2nd ed., Neuchâtel and Paris, 1895); H. E. Jenny, *Die Alpendichtung der deutschen Schweiz* (Bern, 1905); J. C. Mörikofer, *Die schweizerische Literatur des xviii. Jahrhunderts* (Leipzig, 1861); F. Rausch, *Geschichte der Literatur des rhäto-romanischen Volkes* (Frankfort-on-the-Main, 1870); Virgile Rossel, *Histoire littéraire de la Suisse romande* (2 vols., Geneva and Paris, 1889–1891); R. Weber, *Die poetische Nationalliteratur der deutschen Schweiz* (3 vols., Glarus, 1866–1867). For the more recent Swiss writers see the literary sections of the work entitled *La Suisse au xix^me siècle*, vol. ii. ch. 4 (Lausanne, 1889–1900), and the biographers of the several writers noted under the separate articles. (W. A. B. C.)

SWOLD (or Swöld), **BATTLE OF,** the most famous of the sea-fights of the ancient Norsemen. It took place on the 9th of September 1000. The place cannot now be identified, as the formation of the Baltic coast has been much modified in the course of subsequent centuries, partly by the gradual silting up of the sea, and partly by the storms of the 14th century. Swold was an island probably on the North German coast, near Rügen. The battle was fought between Olaf Trygvesson, king of Norway, and a coalition of his enemies—Eric Hakonson, his cousin and rival; Olaf, the king of Sweden; and Sweyn Forkbeard, king of Denmark. The poets, and the poetically minded authors of the sagas, who are the only authorities, have told the story with many circumstances of romance. But when the picturesque details, which also have no doubt at least a foundation of truth, are taken at their true value, the account of the battle still presents a very trustworthy picture of the sea-fighting of the Norsemen. Olaf had been during the summer in the eastern Baltic. The allies lay in wait for him at the island of Swold on his way home. The Norse king had with him seventy-one vessels, but part of them belonged to an associate, Sigwald, a chief of the Jomsburg vikings, who was an agent of his enemies, and who deserted him. Olaf's own ships went past the anchorage of Eric Hakonson and his allies in a long column without order, as no attack was expected. The king was in the rear of the whole of his best vessels. The allies allowed the bulk of the Norse ships to pass, and then stood out to attack Olaf. He might have run past them by the use of sail and oar to escape, but with the true spirit of a Norse warrior he refused to flee, and turned to give battle with the eleven ships immediately about him. The disposition adopted was one which is found recurring in many sea-fights of the middle ages where a fleet had to fight on the defensive. Olaf lashed his ships side to side, his own—the "Long Serpent," the finest war-vessel as yet built in the north—being in the middle of the line, where her bows projected beyond the others. The advantage of this arrangement was that it left all hands free to fight, a barrier could be formed with the oars and yards, and the enemy's chance of making use of his superior numbers to attack on both sides would be, as far as possible, limited—a great point when all fighting was with the sword, or with such feeble missile weapons as bows and javelins. The Norse long ships were high in the bulwark—or, as the Greeks would have said, "cataphract." Olaf, in fact, turned his eleven ships into a floating fort. The Norse writers, who are the only authorities, gave all the credit to their own countrymen, and according to them all the intelligence of Olaf's enemies, and most of their valour, were to be found in Eric Hakonson. They say that the Danes and Swedes rushed at the front of Olaf's line without success. Eric Hakonson attacked the flank. His vessel, the "Iron Ram," was "bearded," that is to say, strengthened across the bows by bands of iron, and he forced her between the last and last but one of Olaf's line. In this way the Norse ships were carried one by one, till the "Long Serpent" alone was left. At last she too was overpowered. Olaf leapt into the sea holding his shield edgeways, so that he sank at once and the weight of his hauberk dragged him down. A legend of later days has it that at the last moment a sudden blaze of light surrounded the king, and when it cleared away he had disappeared. King Olaf is one of the same company as Charlemagne, King Arthur and Sebastian of Portugal—the legendary heroic figures in whose death the people would not believe, and whose return was looked for.

See the *Heims-Kringla*, in the Saga Library, trans. by W. Morris and E. Magmússon (1893) and the *Saga of King Olaf Tryggwason*, trans. by J. Sephton (1895). (D. H.)

SWORD (O. Eng. *sweord*; ultimately from an Indo-European root meaning to wound), a general term for a hand weapon of metal, characterized by a longish blade, and thus distinct from all missile weapons on the one hand, and on the other hand from staff weapons—the pike, bill, halberd and the like—in which the metal head or blade occupies only a fraction of the effective length. The handle of a sword provides a grip for the hand that wields it, or sometimes for two hands; it may add protection, and in most patterns does so to a greater or less extent. Still it is altogether subordinate to the blade. For want of a metal-headed lance or axe, which indeed were of later invention, a sharpened pole or a thin-edged paddle will serve the turn. But a sword-handle without a blade is naught; and no true sword-blade can be made save of metal capable of taking an edge or point.

1. *Historical.*—There are so-called swords of wood and even stone to be found in collections of savage weapons. But these are really flattened clubs; and the present writer agrees with the late General Pitt-Rivers in not believing that such modifications of the club have had any appreciable influence on the form or use of true swords. On this last point, however, the opinions of competent archaeologists have been much divided. We will only remark that the occurrence in objects of human handiwork of a form, or even a series of forms, intermediate between two types is not conclusive evidence that those forms are historical links between the different types, or that there is any historical connexion at all. In the absence of dates fixed by external evidence this kind of comparison will seldom take us beyond plausible conjecture. A traveller who had never seen velocipedes might naturally suppose, on a first inspection, that the tricycle was a modification of the old four-wheeled velocipede, and the bicycle a still later invention; but we know that in fact the order of development was quite different.

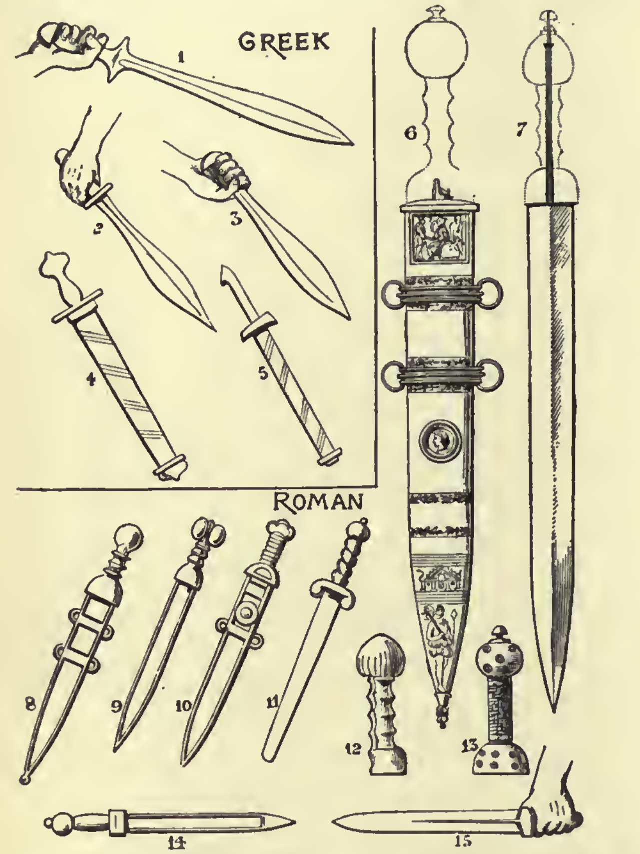
Origins and Early Forms.

It is more difficult as a matter of verbal definition to distinguish the sword from smaller hand weapons. Thus an ordinary sword is four or five times as long as an ordinary dagger: but there are long daggers and short swords; neither will the form of blade or handle afford any certain test. The real difference lies in the intended use of the weapon; we associate the sword with open combat, the dagger with a secret attack or the sudden defence opposed to it. One might say that a weapon too large to be concealed about the person cannot be called a dagger. Again, there are large knives, such as those used by the Afridis and Afghans, which can be distinguished from swords only by the greater breadth of the blade as compared with its length. Again, there are special types of arms, of which the yataghan is a good example, which in their usual forms do not look much like swords, but in others that occur must be classed as varieties of the sword, unless we keep them separate by a more or less artificial theory, referring the type as a whole to a different origin.

Of the actual origin of swords we have no direct evidence. Neither does the English word nor, so far as we are aware, any of the equivalent words in other languages, Aryan or otherwise, throw any light on the matter. Daggers shaped from reindeer antlers occur among the earliest relics of man, and there are flint daggers of the Neolithic period, which may be supposed to have been the model for the first hand weapons made of copper. Bronze took the place of copper about 2000 B.C., and the transition from bronze to iron is assigned to the period from 1000 to 700 B.C.[1] Whatever may be the further discoveries of archaeologists, we know that swords are found from the earliest

[1] As to the overlapping of the bronze and iron ages in the Homeric poems, see Burrows, *The Discoveries in Crete* (1907), p. 214. As to Britain, O. Montelius in *Archaeologia*, 61, pp. 155–6; Cowper, *Art of Attack*, 124 sqq. (Ulverston, 1906).

times of which we have any record among all people who have acquired any skill in metal-work. There are two very ancient types, which we may call the straight-edged and the leaf-shaped. Assyrian monuments represent a straight and narrow sword, better fitted for thrusting than cutting. Bronze swords of this form have been found in many parts of Europe, at Mycenae, side by side with leaf-shaped specimens, and more lately in Crete.[1] We have also from Mycenae some very curious and elaborately wrought blades, so broad and short that they must be called ornamental daggers rather than swords. The leaf-shaped blade is common everywhere among the remains of men in the "Bronze Period" of civilization, and this was the shape used by the Greeks in historical times, and is the shape familiar to us in Greek works of art. It is impossible, however, to say whether the Homeric heroes were conceived by the poet as wearing the leaf-shaped sword, as we see it, for example, on the Mausoleum sculptures, or a narrow straight-edged blade of the Minoan and Mycenaean pattern. In any case, the sword holds a quite inferior position with Greek warriors of all times.



(1–5, from Gerhard's *Griechische Vasenbilder*; 6–15, from Lindenschmit, *Tracht und Bewaffnung des römischen Heeres während der Kaiserzeit*, Brunswick, 1882.)

11, 14, 15, From Trajan's column.

The relation of the Minoan long sword to the Greek leaf-shaped blade is obscure. It is conceivable that the leaf-shape was modified from a longer straight blade for the sake of handiness and cutting power, but not less so that the leaf-shape was independently produced by imitation in metal of flint daggers. Independence appears, on the whole, slightly more probable; the existence of specimens which might belong to an intermediate type is only an ambiguous fact without a more exact chronology than we have as yet, as it may be due to experiment or imitation after both types were in use. Strange as it is to a modern swordsman, representations in Minoan art seem to show that not only the bronze daggers but the long swords were used with an overhand stabbing action like a modern Asiatic dagger.[2] The handles are too short for any but a rigid grip without finger-play. Before about 1500 B.C. the rapier type was the prevailing one; but there is no evidence of historical connexion between the Assyrian and the Minoan rapiers. It is thought that the leaf-shaped blade came to the Mediterranean countries from the north. So far as we know from works of art, it was mostly used with a downright cutting blow, regardless of the consequent exposure of the swordsman's body; this, however, matters little when defence is left to a shield or armour, or both. Attic vases also show warriors giving point, though less often. The use of the sword as a weapon of combined offence and defence—swordsmanship as we now understand it—is quite modern. If the sword was developed from a spearhead or dagger, it would naturally have been (and it seems in fact to have been) a thrusting weapon before it was a cutting one. But when we come to historical times we find that uncivilized people use only the edge, and that the effective use of the point is a mark of advanced skill and superior civilization. The Romans paid special attention to it, and Tacitus tells us how Agricola's legionaries made short work of the clumsy and pointless arms of the Britons when battle was fairly joined.[3] The tradition was preserved at least as late as the time of Vegetius, who, as a technical writer, gives details of the Roman soldier's sword exercise. Asiatics to this day treat the sword merely as a cutting weapon, and most Asiatic swords cannot be handled in any other way.

Historical Types.

The normal types of swords which we meet with in historical times, and from which all forms now in use among civilized nations are derived, may be broadly classified as straight-edged or curved. In the straight-edged type, in itself a very ancient one, either thrusting or cutting qualities may predominate, and the blade may be double-edged or single-edged. The double-edged form was prevalent in Europe down to the 17th century. The single-edged blade, or back-sword as it was called in England, is well exemplified among the Scottish weapons commonly but improperly known as claymores (the real claymore, *i.e.* great sword, *claidheamh mór*, is an earlier medieval form), and is now all but exclusively employed for military weapons. But these, with few exceptions, have been more or less influenced by the curved Oriental sabre. Among early double-edged swords the Roman pattern (*gladius*, the thrusting sword, contrasted with the barbarian *ensis*) stands out as a workmanlike and formidable weapon for close fight. In the middle ages the Roman tradition disappeared, and a new start was made from the clumsy barbarian arm which the Romans had despised. Gradually the broad and all but pointless blade was lightened and tapered, and the thrust, although its real power was unknown, was more or less practised from the 12th century onwards. St Louis anticipated Napoleon in calling on his men to use the point; and the heroes of dismounted combats in the *Morte d'Arthur* are described as "foining" at one another. In the first half of the 16th century a well-proportioned and well-mounted cut-and-thrust sword was in general use, and great artistic ingenuity was expended, for those who could afford it, on the mounting and adornment. The growth and variations of the different parts of the hilt, curiously resembling those of a living species, would alone be matter enough for an archaeological study. One peculiar form, that of the Scottish basket-hilt, derived from the Venetian pattern known as *schiavone*, has persisted without material change.

[1] The Cretan finds are fully described by Arthur J. Evans, "The Prehistoric Tombs of Knossos," (*Archaeologia* (1905), 59, pt. 2; also separately published (1906). There are long (91–95 cm., 34·1 in.–37·1 in.) and short (50–61 cm., 20–24·2 in.), swords, daggers and bronze knives. A fine original specimen and several facsimiles (Mycenaean as well as Minoan) may be seen in the Ashmolean Museum at Oxford. Bronze daggers preceded both swords and spear-heads (Greenwell and Brewis, in *Archaeologia*, 61, pp. 443, 453).

[2] As the spear still was in historical times (Furtwängler-Reichhold, *Gr. Vasenmalerei*, iii. 122).

[3] *Agric.* 36: "Britannorum gladii sine mucrone complexum armorum et in aperto pugnam non tolerabant." The short Roman infantry sword, however, dates only from the Second Punic War.

Quite different from the European models is the crescent-shaped Asiatic sabre, commonly called scimitar. We are not acquainted with any distinct evidence as to the origin of this in time or place. Dr R. Forrer thinks the whole family of curved swords was developed from bronze knives. The Frankish *scramasax* would then represent an intermediate type. However that may be, the fame of the Damascus manufacture of sword-blades is of great antiquity, as is also that of Khorāsān, still the centre of the best Eastern work of this kind. Whoever first made these blades had conceived a very definite idea—that of gaining a maximum of cutting power regardless of loss in other qualities—and executed it in a manner not to be improved upon. The action of the curved edge in delivering a blow is to present an oblique and therefore highly acute-angled section of the blade to the object struck, so that in effect the cut is given with a finer edge than could safely be put on the blade in its direct transverse section. In a well-made sabre the setting of the blade with regard to the handle ("leading forward") is likewise ordered with a view to this result. And the cutting power of a weapon so shaped and mounted is undoubtedly very great. But the use of the point is abandoned,

FIG. 2.—Oriental Swords.

1, 2, Decorated Persian arms.
3, Gauntlet sword.
4, Common type of talwar (North-West Provinces).
5, Yataghan type.
6, Persian talwar.
8, Kukri (Nepal).
7, 9, 10, Mahratta, showing transition to gauntlet sword.

and the capacities of defensive use (to which Orientals pay little or no attention) much diminished. These drawbacks have caused the scimitar type, after being in fashion for European light cavalry during the period of Napoleon's wars and somewhat longer, to be discarded in our own time. But, as long as Easterns adhere to their rigid grasp of a small handle and sweeping cut delivered from the shoulder, the Persian scimitar or Indian talwar will remain the natural weapon of the eastern horseman. Indian and Persian swords are often richly adorned; but their appropriate beauty is in the texture of the steel itself, the "damascening" or "watering" which distinguishes a superior from a common specimen.

There are special Asiatic varieties of curved blades of which the origin is more or less uncertain. Among these the most remarkable is perhaps the yataghan, a weapon pretty much coextensive with the Mahommedan world, though it is reported to be not common in Persia. It was imported from Africa, through a French imitation, as the model of the sword-bayonets which were common for about a generation in European armies; probably the French authorities caught at it to satisfy the sentiment, which lingered in continental armies long after it had disappeared in England, that even the infantry soldier after the invention of the bayonet must have some kind of sword. A compact and formidable hand weapon was thus turned into a clumsy and top-heavy pike. If we try to make a bayonet that will cut cabbages, we may or may not get a useful chopper, but we shall certainly get a very bad bayonet. The modern short sword-bayonet is a reversion to the original dagger type, and not open to this objection. The double curve of the yataghan is substantially identical with that of the Gurkha knife (*kukri*), though the latter is so much broader as to be more like a woodman's than a soldier's instrument. It is doubtful, however, whether there is any historical connexion. Similar needs are often capable of giving rise to similar inventions without imitation or communication. There are yet other varieties, belonging to widely spread families of weapons, which have acquired a strong individuality. Such are the swords of Japan, which are the highly perfected working out of a general Indo-Chinese type; they are powerful weapons and often beautifully made, but a European swordsman would find them ill-balanced, and the Japanese style of sword-play, being two-handed, has little to teach us.

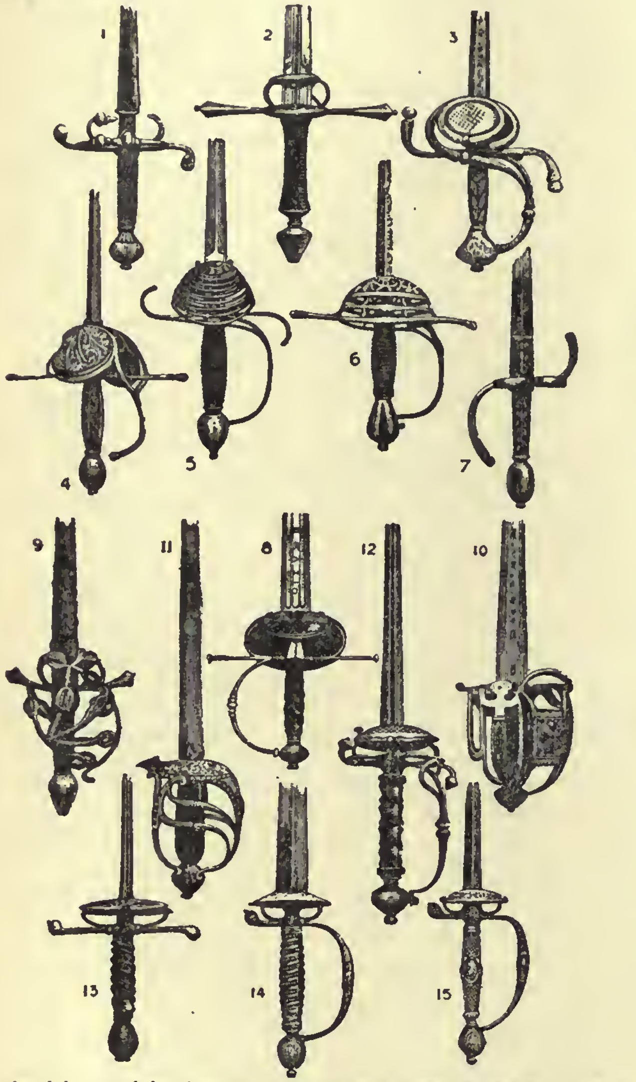
Other sorts of weapons, again, are so peculiar in form or historical derivation, or both, as to refuse to be referred to any of the normal divisions. The long straight gauntlet-hilted sword (*paṭā*, fig. 3) found both among the Mahrattas in the south of India and among the Sikhs and Rajputs in the north, is an elongated form of the broad-bladed dagger with a cross-bar handle (*kaṭār*, figs. 9, 10), as is shown by a transitional form, much resembling in shape and size of blade the medieval English anlace, and furnished with a guard for the back of the hand. This last-mentioned pattern seems, however, to be limited to a comparatively small region. When once the combination of a long blade with the gauntlet hilt was arrived at, any straight blade might be so mounted; and many appear on examination to be of European workmanship—German, Spanish or Italian. There are various other Oriental arms, notably in the Malay group, as to which it is not easy to say whether they are properly swords or not. The Malay "parang latok" is a kind of elongated chopper sharpened by being bevelled off to an edge on one side, and thus capable of cutting only in one direction. The anlace incidentally mentioned above seems to be merely an overgrown dagger; the name occurs only in English and Welsh; in which language first, or whence the name or thing came, is unknown.

Later European Developments.

In the course of the 16th century the straight two-edged sword of all work was lengthened, narrowed, and more finely pointed, till it became the Italian and Spanish rapier, a weapon still furnished with cutting edges, but used chiefly for thrusting. We cannot say how far this transition was influenced by the *estoc* or *Panzerstecher*,[1] a late medieval thrusting weapon carried by horsemen rather as an auxiliary lance than as a sword. The Roman preference of the point was rediscovered under new conditions, and fencing became an art. Its progress was from pedantic complication to lucidity and simplicity, and the fashion of the weapon was

[1] Probably this was the kind of sword called *Broch* in 14th-century English (*Eyre of Kent*, Selden Soc., 1910, p. 100).

simplified also. Early in the 18th century, the use of the edge having been finally abandoned in rapier-play, the two-edged blade was supplanted by the bayonet-shaped French duelling sword, on which no improvement has since been made except in giving it a still simpler guard. The name of rapier was often but wrongly given to this by English writers. About the same time, or a little earlier, the primacy of the art passed from Italy to France. There is still a distinct Italian school, but the rest of the world learns from French masters. It is unnecessary here to consider the history of fencing (*q.v.*); Mr Egerton Castle's book on the subject will be found a trustworthy guide, and almost indispensable for those who wish really to understand the passages relating to sword-play in our Elizabethan literature, of which the fencing scene in *Hamlet* is the most famous and obvious example.



(Reproduced by permission from Mr Egerton Castle's *Schools and Masters of Fence.*)

FIG. 3.—Typical European Swords, 16th–18th centuries.

1, Early 16th century.

7, English musketeer's sword, early 17th century.
8, Spanish broadsword, early 17th century.
9, Venetian, *c.* 1550.
10, Italian, late 16th century.
11, English, time of Commonwealth.
12, French rapier, *c.* 1650.
13, German flamberg, early 17th century.
14, 15, Small-swords, 1700–1750.

Meanwhile a stouter and broader pattern, with sundry minor varieties, continued in use for military purposes, and gradually the single-edged form or broadsword prevailed. The well-known name of Ferrara, peculiarly associated with Scottish blades, appears to have originally belonged to a Venetian maker, or family of makers, towards the end of the 16th century. The Spanish blades made at Toledo had by that time acquired a renown which still continues. Somewhat later Oriental examples, imported probably by way of Hungary, induced the curvature found in most recent military sabres, which, however, is now kept within such bounds as not to interfere with the effective use of the point. An eccentric specialized variety—we may call it a "sport"—of the sabre is the narrow and flexible "Schläger" with which German students fight their duels (for the most part not arising out of any quarrel, but set trials of skill), under highly conventional rules almost identical with those of the old English "backswording" practised within living memory, in which, however, the swords were represented by sticks. These "Schläger" duels cause much effusion of blood, but not often serious danger to life or limb.

There are plenty of modern books on sabre-play, but comparatively little attention has been given to its scientific treatment. It is said that the Italian school is better than the French, and the modern German and Austrian the best of all. Some of the English cavalry regiments have good traditions, enriched by the application of a knowledge of fencing derived from eminent French masters.

Manufacture of Swords by Hand-work.

The following description, written for the 9th edition of this work from personal inspection, applies to the process used by the best private makers till near the end of the 19th century, and is purposely left unchanged. The present method of making army swords is separately described below. Mechanical invention has not been able to supersede or equal hand-work in the production of good sword-blades. The swordsmith's craft is still, no less than it was in the middle ages, essentially a handicraft, and it requires a high order of skill. His rough material is a bar of cast and hammered steel tapering from the centre to the ends; when this is cut in two each half is made into a sword. The "tang" which fits into the handle is not part of the blade, but a piece of wrought iron welded on to its base. From this first stage to the finishing of the point it is all hammer and anvil work. Special tools are used to form grooves in the blade according to the regulation or other pattern desired, but the shape and weight of the blade are fixed wholly by the skilled hand and eye of the smith. [Machine forging in the early stages is now common, and there is no difficulty in making the blade and tang of the same metal.] Measuring tools are at hand, but are little used. Great care is necessary to avoid overheating the metal, which would produce a brittle crystalline grain, and to keep the surface free from oxide, which would be injurious if hammered in. In tempering the blade the workman judges of the proper heat by the colour. Water is preferred to oil by the best makers, notwithstanding that tempering in oil is much easier. With oil there is not the same risk of the blade coming out distorted and having to be forged straight again (a risk, however, which the expert swordsmith can generally avoid); but the steel is only surface-hardened, and the blade therefore remains liable to bend. [This is disputed.] Machinery comes into play only for grinding and polishing, and to some extent in the manufacture of hilts and appurtenances. The finished blade is proved by being caused to strike a violent blow on a solid block with the two sides flat, with the edge, and lastly with the back; after this the blade is bent flatwise in both directions by hand, and finally the point is driven through a steel plate about an eighth of an inch thick. In spite of all the care that can be used both in choice of material and in workmanship, about 40% of the blades thus tried [now only about 10%] fail to stand the proof, and are rejected. The process we have briefly described is that of making a really good sword; of course, plenty of cheaper and commoner weapons are in the market, but they are hardly fit to trust a man's life to. It is an interesting fact that the peculiar skill of the swordsmith is in England so far hereditary that it can be traced back in the same families for several generations.

The best Eastern blades are justly celebrated, but they are not better than the best European ones; in fact, European swords are often met with in Asiatic hands, remounted in Eastern fashion.

The "damascening" or "watering" of choice Persian and Indian arms is not a secret of workmanship, but is due to the peculiar manner of making the Indian steel itself, in which a crystallizing process is set up; when metal of this texture is forged out, the result is a more or less regular wavy pattern running through it. There were early medieval damascened (in German called *wurmbunte*) blades. No difference is made by this in the practical qualities of the blade. (F. Po.)

2. *Modern Military Swords.*—The present military swords are descended from the straight "back-sword" and the Eastern scimitar or talwar. The difference between the curved "sabre" and straight "sword" has been preserved abroad, not only in fact but in name (*e.g.* in German, *Degen* stands for the straight, and *Säbel* for the curved, sword), though in English the single word "sword" covers both varieties. The shape of the sword has varied considerably at different times; this is due to the fact that it is practically impossible to decide by trial whether a straight or a curved sword is the better under all circumstances. The trooper can use his sword in three different ways—to cut, to guard and to point; and his success depends upon the training of his horse, his skill in horsemanship, and, above all, upon the dexterity and methods of his adversary. Thus the effect the cavalryman can produce in combat depends upon much besides his arm or arms, and those other conditions cannot be reproduced accurately enough to make trustworthy tests. The result is that changes have often been made in cavalry armament under the erroneous impression that the arm used has been the main cause of success. The Ottoman cavalry up to the end of the 18th century was regarded as one of the best in Europe, and so much was it dreaded that the Austrians and Russians in their wars with Turkey at that time often carried "chevaux-de-frise" to protect their infantry against these redoubtable horsemen. The curved European cavalry sabre so long in use may undoubtedly be traced to this cause, the superiority of the Turks being put down to their curved scimitars, though there can be no doubt that horsemanship and dash were really the dominating factors.

The shape of the sword to be chosen depends obviously on the purpose for which it is mainly intended. If for cutting a curved blade, and for thrusting a straight and pointed one, will be adopted. The question naturally arises as to which is the better plan to adopt, and it is improbable that a definite answer can ever be given to it. The French, for instance, in 1822 adopted a curved blade for a short time for all their cavalry, and in 1882 again for a short time a straight blade, and in 1898 again a straight blade. In this much-debated matter the facts appear to be as follows: A determined thrust, especially when delivered by a horseman at full speed, is difficult to parry: if it gets home, it will probably kill the recipient outright or disable him for the rest of the campaign. That this is the case is borne out by the very large proportion of killed as compared with wounded in the British cavalry when engaged with that of the French in the Peninsular War, the French making much use of the point, and their heavy cavalry being armed with a long straight sword. On the other hand, to deliver a bold thrust, while disregarding the uplifted sword of the adversary, and leaving one's own body and head open to an impending blow, demands complete confidence that the thrust will get home before the blow can descend, or that the adversary's cut will probably be weakened by a momentary uncertainty as to whether it would not be better to convert the intended cut into a parry. Such confidence, it is argued with much truth, can only be the fruit of long training, especially as it is the natural tendency of all men to cut when excited; therefore, as the trooper in modern armies will often be a reservist who has not been able to keep up his swordsmanship, or a young soldier liable to lose his head and forget the lessons of peace in the excitement of the *mêlée*, it is considered by many most unwise to adopt a sword with which a powerful cut cannot be delivered as well as an effective thrust. The swords recently adopted by most nations have represented a compromise. They have blades which are nearly straight, but of sufficient weight towards their points to enable an efficient cut to be delivered with them. France, however, in 1898 decided on a long straight sword designed wholly for thrusting (see fig. 1), practically identical with that which was in use about a century ago. The following year Great Britain introduced a slightly curved weapon, but in 1908 a new sword was adopted which has a long straight blade and is intended to be used chiefly for thrusting.

As regards the swords worn by officers and men of corps other than cavalry, no remarks are necessary. As long as they are worn they should be efficient; but with the officer the sword is largely a badge of rank. From 1901 to 1908 the sword was worn only for ceremonial purposes by British infantry officers, but in the latter year it was again ordered to be worn on active service and at manœuvres. Mounted men in general wear cavalry swords, and swords are also worn by warrant officers and by certain staff-sergeants of dismounted arms and branches.

A good sword should be elastic, so as to stand bending or a heavy blow without breaking or permanent deformation, and yet stiff enough to deliver a powerful thrust without yielding too readily from the straight; it must also be as light as is possible consistently with strength, and well balanced. All four desiderata are met in the main by the use of a suitable steel, properly treated and disposed, but balance is also dependent on the weight and form of the hilt. As regards the effect of disposition, grooving or "fullering" the flats of the blade reduces weight without impairing strength, and is now very largely adopted.

The operations of manufacture, as carried out at the Royal Small Arms Factory at Enfield, may be described briefly as follows, the weapon being the pattern 1899 cavalry sword, which was slightly curved:—

The steel blank, about $17'' \times 1\frac{1}{4}'' \times \frac{1}{2}''$, is heated and drawn out to about double its length under a mechanical hammer; it is then reheated and rolled out between rolls suitably shaped, and the fullers formed; the tang (to which the hilt and grips are ultimately attached) is then formed by stamping under a machine hammer, and the blade is cut to length and roughly pointed. The blade, though approximately in its finished form, is now straight; the fins are ground off, the tang annealed, the blade set for grinding, and afterwards rough-ground. It is heated and set to curve in a press, then reheated and hardened by being plunged into a bath of oil kept cool by a water jet. On removal from the bath the blade is dead hard and so brittle that it can be broken by a slight blow, and consequently has to be let down by tempering. This is accomplished by heating in a bath of molten lead until the steel assumes a particular colour, at which stage, while hot, the blade is adjusted for straightness and curve, this being a delicate operation, as it must be performed while the blade retains its temper and heat before finally cooling. It is now ground to size, and the tang, which, though not hardened purposely, is harder than is desired for machining, is softened by cooling, and machined to the required form. The blade is then ground, reheated to spring temper and set, then tested as follows: When tempered and set before polishing it is fixed in a machine and caused to strike an oak block with a blow of 120 lb with both its edge and back, and with similar blows, but with a force of 60 lb, with both flats. These tests detect flaws, and over or under tempering, by the breakage or distortion of the blade, the blows by the flat being particularly searching tests. If the blade passes the above tests, it is then placed vertically in a machine and shortened 5 in. by bending towards each flat, and must recover perfect straightness; it is then shortened 1 in., and must recover itself when supporting a weight of 35 lb bearing on its tang. This tests the elasticity of the blade. After polishing it is again tested for stiffness as above, and must recover perfect straightness, but only under 32 lb, and for elasticity by a further shortening of 5 in., but towards one flat only.

The introduction of the system described above has greatly simplified and cheapened the process of manufacture, while the greater excellence of the product and the severe and certain tests applied to it by mechanical means have increased the standard of efficiency of the swords in the hands of the troops. It is certainly true that, of old, excellent blades were occasionally turned out by hand, but they were exceedingly costly, and the average merit of sword-blades when turned out in numbers by hand was poor. It must not, however, be supposed that the regular methods described have eliminated the necessity for personal skill. The steel can still be spoilt by over- or under-heating, whether for rolling or hardening; tempering and setting require much experience and skill, and blades can be easily injured both in form and temper by unskilful grinding. Sword-making, therefore, though not the somewhat uncertain art it once was, still requires skilled craftsmen for its successful accomplishment. (H. W. B.; F. Po.)

AUTHORITIES.—The following list of works is intended to guide the reader, if desired, to fuller acquaintance with the literature and authorities of the subject:—

Archaeology and General History.—R. Forrer, "Der Werdegang von Dolch und Schwert," introduction to *Die Schwerter und Schwertknäufe der Sammlung Carl von Schwerzenbach* (Leipzig, 1905), the best monograph; Dr Julius Naue, *Die vorrömischen Schwerter aus Kupfer, Bronze und Eisen* (Munich, 1903), with atlas of illustrations, a standard work for the prehistoric periods (neither of these authors has been able to use the Cretan materials); R. F. Burton, *The Book of the Sword* (only 1 vol. published; London, 1884); Colonel Lane Fox (afterwards Major-General Pitt-Rivers), *Catalogue of Anthropological Collection, South Kensington Museum* (London, 1874); "Primitive Warfare," in *Journal* of the Royal United Service Institution (1867, 1868, 1869). For special regions and periods, see Lord Egerton of Tatton, *Indian and Oriental Armour* (London, 1896); Lindenschmit, *Tracht und Bewaffnung des römischen Heeres während der Kaiserzeit* (Brunswick, 1882); Drummond and Anderson, *Ancient Scottish Weapons* (Edinburgh and London, 1881). The general treatises and handbooks on arms and armour, such as Grose, Meyrick, Hewitt, Lacombe and Demmin, may be consulted with advantage, but with caution in details. The same may be said of published catalogues of museums and private collections. W. Boeheim, *Handbuch der Waffenkunde* (Leipzig, 1900); R. C. Clephan, *The Defensive Armour and the Weapons and Engines of War of Medieval Times and of the Renaissance* (London, 1900); Ashdown, *British and Foreign Arms and Armour* (London, 1909); and G. F. Laking, *The Armour of Windsor Castle* (European section; London, 1904), are trustworthy guides. "The Forms and History of the Sword," in *Proceedings* of the Royal Institution (1883), by the present writer, reprinted in *Oxford Lectures*, &c. (London, 1890), gives further references and citations on various points.

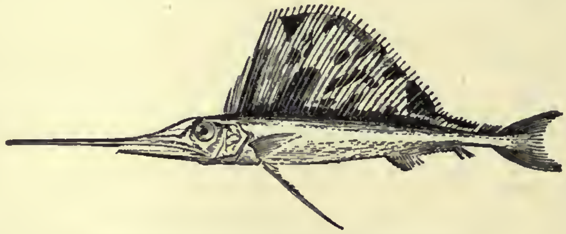
Swordsmanship.—Egerton Castle, *Schools and Masters of Fence from the Middle Ages to the Eighteenth Century* (including a critical bibliography; London, 1892); Carl A. Thimm, *Bibliography of Fencing and Duelling* (London, 1896). For the beginnings of the art in Italy, *Flos duellatorum* (a MS. of 1410 edited by Francesco Novati, with critical introduction and notes, Bergamo, 1902). Vigeant, *Bibliographie de l'escrime ancienne et moderne* (Paris, 1882); Gomard (assumed name of Possellier), *Théorie de l'escrime* (historical introduction; Paris, 1845). Grisier, *Les Armes et le duel* (preface by A. Dumas; Paris, 1847).

Technology.—Wilkinson, *Engines of War* (London, 1841); Latham, "The Shape of Sword-Blades," *Journal* of the Royal U.S. Institution (1862); Marey, *Mémoire sur les armes blanches* (Strassburg, 1841; trans. by Lieut.-Colonel Maxwell, London, 1860).

For the technique of Japanese swords, see A. Dobrée, "Japanese Sword Blades," *Archaeol. Journal*, lxii. 1, 218 (London, 1905); as to export of European blades to India, Lord Dillon, "Arms and Armour Abroad," ibid. 67, 69–72. (F. Po.)

SWORDFISH, the name given to a small family of spiny-rayed fishes (Xiphiidae), the principal characteristic of which consists in the prolongation of the upper jaw into a long pointed sword-like weapon. The "sword" is formed by the coalescence of the intermaxillary and maxillary bones, which possess an extremely hard texture; it has the shape of a much elongated cone, more or less flattened throughout its whole length; the end is sharply pointed. It is smooth above and on the upper part of the sides, and rough below owing to the presence of innumerable rudimentary teeth, which have no function.

The general form of the body is well proportioned, somewhat elongate, and such as is always found in fishes with great power



Swordfish (*Histiophorus pulchellus*).

of swimming, as, for instance, in the mackerel and tunny, and the tail terminates in a powerful bilobed caudal fin. A long fin occupies nearly the whole length of the back, whilst the anal fin is generally interrupted in the middle and consequently appears to be double. The skin is very firm, partly naked, partly with small lanceolate scales deeply embedded in the skin. The teeth of the lower jaw are, like those of the upper, merely rudimentary structures, which render the surface of the bone rough without possessing any special function.

Swordfishes have been divided into three generic groups:—

a. Histiophorus, with a high dorsal fin which can be spread out like a sail, and with ventral fins which are reduced to a pair of long styliform appendages.

b. Tetrapturus, with a dorsal fin of which the anterior rays only are elongate, the remainder of the fin being low or partly obsolete, and with styliform ventral fins as in the preceding genus.

c. Xiphias, with the dorsal fin shaped as in *Tetrapturus*, but without ventral fins.

Swordfishes are truly pelagic fishes, which either singly or in pairs or in smaller or larger companies roam over the oceans of the tropical and subtropical zones of both hemispheres. Some species wander regularly or stray far into the temperate seas. Some of the tropical forms are the largest of Acanthopterygian fishes, and not exceeded in size by any other Teleostean; such species attain to a length of from 12 to 15 ft., and swords have been preserved more than 3 ft. long and with a diameter of at least 3 in. at the base. The *Histiophori*, which inhabit chiefly the Indo-Pacific Ocean, but occur also in the Atlantic, seem to possess in their high dorsal fin an additional aid for locomotion. During the rapid movements of the fish this fin is folded downwards on the back, as it would impede the velocity of progress by the resistance it offers to the water; but, when the fish is swimming in a leisurely way, it is frequently seen with the fin erected, and projecting out of the water, and when quietly floating on the surface it can sail by the aid of the fin before the wind, like a boat.

The food of the swordfishes is the same as that of tunnies, and consists of smaller fish, and probably also in great measure of pelagic cuttle-fishes. It has been ascertained by actual observation that swordfishes procure their food by dashing into a school of fishes, piercing and killing a number of them with their swords; and this kind of weapon would seem to be also particularly serviceable in killing large cuttle-fish, like the saw of sawfishes, which is used for the same purpose. But the swords of the large species of *Histiophorus* and *Tetrapturus* are, besides, most formidable weapons of aggression. These fishes never hesitate to attack whales and other large cetaceans, and, by repeatedly stabbing them, generally retire from the combat victorious. That they combine in these attacks with the thresher-shark is an often-repeated story which is discredited by some naturalists on the ground that the dentition of the thresher-shark is much too weak to make an impression on the skin of any cetacean. The cause which excites swordfishes to such attacks is unknown; but they follow the instinct so blindly that they not rarely assail boats and ships in a similar manner, evidently mistaking them for cetaceans. They easily pierce the light canoes of the natives of the Pacific islands and the heavier boats of the professional swordfish fishermen, often dangerously wounding the persons sitting in them. Attacks by swordfishes on ocean-going ships are so common as to be included among sea-risks: they are known to have driven their weapon through copper-sheathing, oak-plank and timber to a depth of nearly 10 in., part of the sword projecting into the inside of the ship; and the force required to produce such an effect has been described by Sir R. Owen in a court of law as equal to "the accumulated force of fifteen double-handed hammers," and the velocity as "equal to that of a swivel-shot" and "as dangerous in its effects as a heavy artillery projectile." Among the specimens of planking pierced by swordfishes which are preserved in the British Museum there is one less than a foot square which encloses the broken ends of three swords, as if the fishes had had the object of concentrating their attack on the same vulnerable point of their supposed enemy. The part of the sword which penetrates a ship's side is almost always broken off and remains in the wood, as the fish is unable to execute sufficiently powerful backward movements to free itself by extracting the sword.

In the Mediterranean and on the Atlantic coasts of the United States the capture of swordfishes forms a regular branch of the fishing industry. The object of the fishery in the Mediterranean is the common European swordfish (*Xiphias gladius*), the average weight of which is about 1 cwt., and which is abundant off the Sicilian coasts and on the opposite coast of Calabria. Two methods are employed—that by harpoons, chiefly used for larger fish, and that by peculiarly constructed nets called *palamitare*. This fishery is very productive: a company of fishermen frequently capture from twenty to fifty fish in a single day, and the average annual catch in Sicily and Calabria is reported to be 140,000 kilogrammes (138 tons). The products of the fishery are consumed principally in a fresh state, but a portion is preserved in salt or oil. The flesh of the swordfish is much preferred to that of the tunny, and always commands a high price. This species is occasionally captured on the British coast.

On the coast of the United States a different species, *Histiophorus gladius*, occurs; it is a larger fish than the Mediterranean swordfish, attaining to a length of from 7 to 12 ft. and an average weight of 300 or 400 lb. It is captured only by the use of the harpoon. From forty to fifty vessels, schooners of some 50 tons, are annually engaged in this fishery, with an aggregate catch amounting annually to about 3400 swordfishes, of a value of $45,000. The flesh of this species is inferior in flavour to that of the Mediterranean species, and is principally consumed after having been preserved in salt or brine.

Useful and detailed information on the swordfish fishery can be obtained from A. T. Tozzetti, "La Pesca nei mari d'Italia e la pesca all' estero esercitata da Italiani," in *Catalogo esposizione internazionale di pesca in Berlino* (1880); also from *La Pesca del pesce-spada nello Stretto di Messina* (Messina, 1880), and from G. Brown Goode, "Materials for a History of the Sword-fish," in *Report of the Commissioner of Fish and Fisheries*, pt. viii. (Washington, 1883). (A. C. G.)

SWYNFORD, CATHERINE (*c.* 1350–1403), wife of John of Gaunt, duke of Lancaster, was a daughter of Sir Payne Roelt, a knight who came to England from Hainault in the train of Edward III.'s queen, Philippa. About 1367 she married Sir Hugh Swynford (1340–1372), a Lincolnshire man, by whom she had a son, Thomas (*c.* 1368–1433), who was a friend and companion of Henry IV. both before and after he came to the English throne. Soon after her husband's death in 1372 Catherine became the mistress of John of Gaunt, and in 1396, nearly two years after the duke had become a widower for the second time, she was married to him at Lincoln. She died at Lincoln on the 10th of May 1403. By John of Gaunt Catherine had four children, all of whom were born before their marriage. They were declared legitimate in 1397 and took the name of Beaufort from one of their father's castles in Anjou (see BEAUFORT).

SYAGRIUS (d. 487), the last of the independent Roman administrators of Gaul, was the son of Aegidius, who had seized Gaul while Ricimer was master of Italy. From 464 to 486 he governed that part of Gaul which lies between the Maas, the Scheldt and the Seine, and was termed "king of the Romans" by the German invaders, Franks, Burgundians and Visigoths, who already occupied the rest of Gaul. Defeated in 486 by Clovis, king of the Salian Franks, at the battle of Soissons, Syagrius fled, leaving his land at the mercy of the Franks. He sought refuge with Alaric II., king of the Visigoths, at Toulouse, but Alaric imprisoned him instead of granting him refuge, and delivered him up to Clovis. He was executed in 487, secretly and by the sword, according to Gregory of Tours.

SYBARIS, a city of Magna Graecia, on the Gulf of Tarentum, between the rivers Crathis (Crati) and Sybaris (Coscile), which now meet 3 m. from the sea, but in ancient times had independent mouths, was the oldest Greek colony in this region. It was an Achaean colony founded by Isus of Helice (about 720 B.C.), but had among its settlers many Troezenians, who were ultimately expelled. Placed in a very fertile, though now most unhealthy, region, and following a liberal policy in the admission of citizens from all quarters, the city became great and opulent, with a vast subject territory and divers daughter colonies even on the Tyrrhenian Sea (Posidonia, Laus, Scidrus). For magnificence and luxury the Sybarites were proverbial throughout Greece, and in the 6th century probably no Hellenic city could compare with its wealth and splendour. At length contests between the democrats and oligarchs, in which many of the latter were expelled and took refuge at Crotona, led to a war with that city, and the Crotoniats with very inferior forces were completely victorious. They razed Sybaris to the ground and turned the waters of Crathis to flow over its ruins (510 B.C.). Explorations undertaken by the Italian government in 1879 and 1887 failed to lead to a precise knowledge of the site. The only discoveries made were (1) that of an extensive necropolis, some 8 m. to the west of the confluence of the two rivers, of the end of the first Iron age, known as that of Torre Mordillo, the contents of which are now preserved at Potenza; (2) that of a necropolis of about 400 B.C.—the period of the greatest prosperity of Thurii (*q.v.*)—consisting of tombs covered by tumuli (called locally *timponi*), in some of which were found fine gold plates with mystic inscriptions in Greek characters; one of these tumuli was over 90 ft. in diameter at the base with a single burial in a sarcophagus in the centre.

SYBEL, HEINRICH VON (1817–1895), German historian, sprang from a Protestant family which had long been established at Soest, in Westphalia. He was born on the 2nd of December 1817 at Düsseldorf, where his father held important posts in the public service both under the French and the Prussians; in 1831 he had been raised to the hereditary nobility. His home was one of the centres of the vigorous literary and artistic life for which at that time Düsseldorf was renowned. Sybel was educated at the gymnasium of his native town, and then at the university of Berlin, where he came under the influence of Savigny and of Ranke, whose most distinguished pupil he was to become. After taking his degree, he settled down in 1841 as *Privatdozent* in history at the university of Bonn. He had already made himself known by critical studies on the history of the middle ages, of which the most important was his *Geschichte des ersten Kreuzzuges* (Düsseldorf, 1841; new ed., Leipzig, 1881), a work which, besides its merit as a valuable piece of historical investigation, according to the critical methods which he had learnt from Ranke, was also of some significance as a protest against the vaguely enthusiastic attitude towards the middle ages encouraged by the Romantic school. Lady Duff-Gordon published in 1861 an English translation of part of this book, to which are added lectures on the crusades delivered in Munich in 1858, under the title *History and Literature of the Crusades*. This was followed by a study on the growth of German kingship (*Die Entstehung des deutschen Königtums*, Frankfort, 1844, and again 1881), after which he was appointed professor.

In the same year (1844) Sybel came forward prominently as an opponent of the Ultramontane party. The exhibition of the Holy Coat at Trier had attracted enormous numbers of pilgrims, and so, indignant at what appeared to him an imposture, he assisted to publish an investigation into the authenticity of the celebrated relic. From this time he began to take an active part in contemporary politics and in controversy as a strong though moderate Liberal. In 1846 he was appointed professor at Marburg, and though this small university offered little scope for his activities as a teacher, a seat in the Hessian Landtag gave him his first experience of political affairs. In 1848 he was present at Frankfort, but he did not succeed in winning a seat for the National Assembly. His opposition to the extreme democratic and revolutionary party made him unpopular with the mob, who broke his windows, as his liberalism made him suspected at court. He sat in the Erfurt parliament of 1850, and was attached to the Gotha party, which hoped for the regeneration of Germany through the ascendancy of Prussia. During the years that followed all political activity was impossible, but he was fully occupied with his great work *Geschichte der Revolutionszeit 1879-1800*, for which he had made prolonged studies in the archives of Paris and other countries. The later editions of the earlier volumes are much enlarged and altered, and a new edition was published at Stuttgart in 1882. The first three volumes have been translated into English by W. C. Perry (1867–1869). In this work he for the first time showed the connexion between the internal and external history of France; he was also the first, by a systematic study of the records, to check and correct the traditional account of many episodes in the internal history. His demonstration that letters attributed to Marie Antoinette were not genuine roused much interest in France. For the history of German thought it was of the greatest importance that a Liberal from the Rhine, by a systematic history of the Revolution, attempted to overthrow the influence which the revolutionary legend, as expounded by French writers, had acquired over the German mind; and the book was an essential part of the influences which led to the formation of a National Liberal school of thought. Sybel had been much influenced by Burke, on whom he had published two essays. The work was in fact the first attempt to substitute for the popular representations of Thiers and Lamartine the critical investigation which has been carried on with such brilliance by Taine and Sorel.

In 1856, on the recommendation of Ranke, Sybel accepted the post of professor at Munich, where King Maximilian II. of Bavaria, a wise and generous patron of learning, hoped to establish a school of history. He found here a fruitful field for his activity. Besides continuing his work on the Revolution and on the middle ages, he was occupied with the *Historical Seminar* which he instituted; with the *Historische Zeitschrift* which he founded, the original and model of the numerous technical historical publications which now exist; and as secretary of the new historical commission. Political differences soon interfered with his work; as an adherent of Prussia and a Protestant, especially as a militant champion against the Ultramontanes, he was from the first an object of suspicion to the Clerical party. In the political excitement which followed the war of 1859 he found that he could not hope for the unreserved support of the king, and therefore in 1861 he accepted a professorship at Bonn, which he held till 1875. He was at once elected a member of the Prussian Lower House, and during the next three years was one of the most active members of that assembly: in several important debates he led the attack on the government, and opposed the policy of Bismarck, not only on financial but also on the Polish and Danish affairs. In 1864 he did not stand for re-election, owing to an affection of the eyes, but in 1866 he was one of the first to point out the way to a reconciliation between Bismarck and his former opponents. He had a seat in the Constituent Assembly of 1867, and while he joined the National Liberals he distinguished himself by his opposition to the introduction of universal suffrage, the effects of which he, as did many other Liberals, much distrusted. In 1874 he again accepted a seat in the Prussian parliament, in order to support the government in their conflict with the Clericals, and after 1878 with the Socialists. In two pamphlets, by an analysis of the teaching of the Socialists and a survey of Clerical policy during the 19th century, he explained and justified his opinions. In 1880 he retired, like so many other Liberals, disheartened by the change in political life, which he attributed to universal suffrage.

In 1875 he had been appointed by Bismarck to the post of director of the Prussian archives. Under his superintendence was begun the great series of publications, besides that of the correspondence of Frederick the Great, in the editing of which he himself took part. His last years were occupied on his great work, *Die Begründung des deutschen Reiches durch Wilhelm I.* (Munich, 1889–1894), a work of great importance, for he was allowed to use the Prussian state papers, and was therefore enabled to write a history of the greatest events of his own time with full access to the most secret sources of information. As a history of Prussian policy from 1860 to 1866 it is therefore of incomparable value. After the fall of Bismarck the permission to use the secret papers was withdrawn, and therefore vols. vi. and vii., which deal with the years 1866 to 1870, are of less importance. This work has been translated into English as *The Founding of the German Empire*, by M. L. Perrin and G. Bradford (New York, 1890–1891). Sybel did not live to write the account of the war with France, dying at Marburg on the 1st of August 1895. His other writings include *Die deutsche Nation und das Kaiserreich* (1862) and a large number of historical articles.

Sybel left two sons, one of whom became an officer in the Prussian army; the other, Ludwig von Sybel (b. 1846), professor of archaeology in the university of Marburg, is the author of several works dealing with Greek archaeology.

Some of Sybel's numerous historical and political essays have been collected in *Kleine historische Schriften* (3 vols., 1863, 1869, 1881; new ed., 1897); *Vorträge und Aufsätze* (Berlin, 1874); and *Vorträge und Abhandlungen*, published after his death with a biographical introduction by C. Varrentrapp (Munich, 1897).

SYCOPHANT (Gr. *συκοφάντης*), in ancient Greece the counterpart of the Roman delator (*q.v.*), a public informer. According to ancient authorities, the word (derived by them from *σῦκον*, "fig," and *φαίνειν*, "to show") meant one who informed against another for exporting figs (which was forbidden by law) or for stealing the fruit of the sacred fig-trees, whether in time of famine or on any other occasion. Another old explanation was that fines and taxes were at one time paid in figs, wine and oil, and those who collected such payments in kind were called sycophants because they "presented," publicly handed them over to the state. Böckh suggested that the word signified one who laid an information in reference to an object of trifling value, such as a fig (cf. "I don't care a fig about it"), but there seems no authority for such a use of σῦκον in Greek. According to C. Sittl (*Die Gebärden der Griechen und Römer*, Leipzig, 1890), the word refers to an obscene gesture of phallic significance (see also A. B. Cook in *Classical Review*, August 1907), called "showing the fig" (*faire la figue, far la fica* or *le fiche*), originally prophylactic in character. Such gesture, directed towards an inoffensive person, became an insult, and the word sycophant might imply one who insulted another by bringing a frivolous or malicious accusation against him. According to S. Reinach (*Revue des études grecques*, xix., 1906), who draws special attention to the similar formation "hierophant," the sycophant was an official connected with the cult of the Phytalidae, whose eponymus Phytalus was rewarded with a fig-tree by the wandering Demeter in return for his hospitality. The final act of the cult, the "exaltation" of the fig, with which Reinach compares the "exaltation" of the ear of corn by the hierophant at the Eleusinian mysteries, was performed by the sycophant. Again, like the hierophant, the sycophant publicly pronounced the formula of exclusion of certain unworthy persons from the celebration of the mysteries of the fig. As the cult of the Phytalidae sank into insignificance beside the greater mysteries, the term sycophant survived in popular language in the sense of an informer or denouncer, whose charges deserved but little consideration. L. Shadwell suggests that the real meaning is "fig-discoverer," not "fig-informer," referring to the blackmailer who discovers the "figs" (that is, the money) of the rich man and forces him to hand it over by the threat of bringing a criminal accusation against him. It must be remembered that any Athenian citizen was at liberty to accuse another of a public offence, and the danger of such a privilege being abused is sufficiently obvious. The people naturally looked upon all persons of wealth and position with suspicion, and were ready to believe any charge brought against them. Such prosecutions also put money into the pockets of the judges, and, if successful, into the public treasury. In many cases the accused persons, in order to avoid the indignity of a public trial, bought off their accusers, who found in this a fruitful source of revenue. Certain legal remedies, intended to prevent the abuses of the system, undoubtedly existed. Persons found guilty of bringing false charges, of blackmail, or of suborning false witnesses, were liable to criminal prosecution by the state and a fine on conviction. Penalties were also inflicted if an accuser failed to carry the prosecution through or to obtain a fifth part of the votes. But these remedies were rather simple deterrents, and instances of informers being actually brought to trial are rare. Sycophants were an inseparable accompaniment of the democracy, and the profession, at least from a political point of view, was not regarded as in any way dishonourable. The idea of encouraging the citizens to assist in the detection of crime or treason against the state was commendable; it was not the use, but the abuse of the privilege that was so injurious. Allusions to the sycophants are frequent in Aristophanes and the Attic orators. The word is now generally used in the sense of a cringing flatterer of the great.

See Meier and Schömann, *Der attische Process* (ed. J. H. Lipsius, 1883–1887); article by C. R. Kennedy and H. Holden, in Smith's *Dictionary of Antiquities* (3rd ed., 1891).

SYDENHAM, CHARLES EDWARD POULETT-THOMSON, 1ST BARON (1799–1841), British statesman, was born on the 13th of September 1799, being the son of John Buncombe-Poulett-Thomson, a London merchant. After some years spent in his father's business in Russia and in London he was returned to the House of Commons for Dover in 1826. In 1830 he joined Lord Grey's ministry as vice-president of the board of trade and treasurer of the navy. A free-trader and an expert in financial matters he was elected M.P. for Manchester in 1832, a seat which he occupied for many years. He was continuously occupied with negotiations affecting international commerce until 1839, when he accepted the governor-generalship of Canada, where it fell to his lot to establish the union of Upper and Lower Canada. His services in establishing the Canadian constitution were recognized in 1840 by a K.C.B. and a peerage. He took the title of Baron Sydenham of Sydenham in Kent and Toronto in Canada. He died unmarried on the 4th of September 1841, when his peerage became extinct.

His *Memoirs* were published by his brother, G. J. Poulett Scrope, in 1843.

SYDENHAM, THOMAS (1624–1689), English physician, was born on the 10th of September 1624 at Wynford Eagle in Dorset, where his father was a gentleman of property and good pedigree. At the age of eighteen he was entered at Magdalen Hall, Oxford; after a short period his college studies appear to have been interrupted, and he served for a time as an officer in the army of the parliament. He completed his Oxford course in 1648, graduating as bachelor of medicine, and about the same time he was elected a fellow of All Souls College. It was not until nearly thirty years later (1676) that he graduated as M.D., not at Oxford, but at Pembroke Hall, Cambridge, where his eldest son was then an undergraduate. After 1648 he seems to have spent some time studying medicine at Oxford, but he was soon again engaged in military service, and in 1654 he received the sum of £600, as a result of a petition he addressed to Cromwell, setting forth that various arrears were due to two of his brothers who had been killed and that he himself had faithfully served the parliament with the loss of much blood. In 1655 he resigned his fellowship at All Souls and married, and probably a few years later went to study medicine at Montpellier. In 1663 he passed the examinations of the College of Physicians for their licence to practice in Westminster and 6 m. round; but it is probable that he had been settled in London for some time before that. This minimum qualification to practise was the single bond between Sydenham and the College of Physicians throughout the whole of his career. He seems to have been distrusted by some members of the faculty because he was an innovator and something of a plain-dealer. In his letter to John Mapletoft he refers to a class of detractors "qui vitio statim vertunt si quis novi aliquid, ab illis non prius dictum vel etiam inauditum, in medium proferat"; and in a letter to Robert Boyle, written the year before his death (and the only authentic specimen of his English composition that remains), he says, "I have the happiness of curing my patients, at least of having it said concerning me that few miscarry under me; but [I] cannot brag of my correspondency with some other of my faculty . . . . Though yet, in taken fire at my attempts to reduce practice to a greater easiness, plainness, and in the meantime letting the mountebank at Charing Cross pass unrailed at, they contradict themselves, and would make the world believe I may prove more considerable than they would have me." Sydenham attracted to him in warm friendship some of the most discriminating men of his time, such as John Locke and Robert Boyle. His first book, *Methodus curandi febres*, was published in 1666; a second edition, with an additional chapter on the plague, in 1668; and a third edition, much enlarged and bearing the better-known title of *Observationes medicae*, in 1676. His next publication was in 1680 in the form of two *Epistolae responsoriae*, the one, "On Epidemics," addressed to Robert Brady, regius professor of physic at Cambridge, and the other "On the Lues venerea," to Henry Paman, public orator at Cambridge and Gresham professor in London. In 1682 he issued another *Dissertatio epistolaris*, on the treatment of confluent small-pox and on hysteria, addressed to Dr William Cole of Worcester. The *Tractatus de podagra et hydrope* came out in 1683, and the *Schedula monitoria de novae febris ingressu* in 1686. His last completed work, *Processus integri*, is an outline sketch of pathology and practice; twenty copies of it were printed in 1692, and, being a compendium, it has been more often republished both in England and in other countries than any other of his writings separately. A fragment on pulmonary consumption was found among his papers. His collected writings occupy about 600 pages 8vo, in the Latin, though whether that or English was the language in which they were originally written is disputed.

Hardly anything is known of Sydenham's personal history in London. He died in London on the 29th of December 1689, and was buried in the church of St James's, Piccadilly, where a mural slab was put up by the College of Physicians in 1810.

Although Sydenham was a highly successful practitioner and saw, besides foreign reprints, more than one new edition of his various tractates called for in his lifetime, his fame as the father of English medicine, or the English Hippocrates, was decidedly posthumous. For a long time he was held in vague esteem for the success of his cooling (or rather expectant) treatment of small-pox, for his laudanum (the first form of a tincture of opium), and for his advocacy of the use of Peruvian bark in quartan agues. There were, however, those among his contemporaries who understood something of Sydenham's importance in larger matters than details of treatment and pharmacy, chief among them being the talented Richard Morton. But the attitude of the academical medicine of the day is doubtless indicated in Martin Lister's use of the term "sectaries" for Sydenham and his admirers, at a time (1694) when the leader had been dead five years. If there were any doubt that the opposition to him was quite other than political, it would be set at rest by the testimony of Dr Andrew Brown,[1] who went from Scotland to inquire into Sydenham's practice and has incidentally revealed what was commonly thought of it at the time, in his *Vindicatory Schedule concerning the New Cure of Fevers*. In the series of Harveian orations at the College of Physicians, Sydenham is first mentioned in the oration of Dr John Arbuthnot (1727), who styles him "aemulus Hippocratis." H. Boerhaave, the Leyden professor, was wont to speak of him in his class (which had always some pupils from England and Scotland) as "Angliae lumen, artis Phoebum, veram Hippocratici viri speciem." A. von Haller also marked one of the epochs in his scheme of medical progress with the name of Sydenham. He is indeed famous because he inaugurated a new method and a better ethics of practice, the worth and diffusive influence of which did not become obvious (except to those who were on the same line with himself, such as Morton) until a good many years afterwards. It remains to consider briefly what his innovations were.

First and foremost he did the best he could for his patients, and made as little as possible of the mysteries and traditional dogmas of the craft. All the stories told of him are characteristic. Called to a gentleman who had been subjected to the lowering treatment, and finding him in a pitiful state of hysterical upset, he "conceived that this was occasioned partly by his long illness, partly by the previous evacuations, and partly by emptiness. I therefore ordered him a roast chicken and a pint of canary." A gentleman of fortune who was a victim to hypochondria was at length told by Sydenham that he could do no more for him, but that there was living at Inverness a certain Dr Robertson who had great skill in cases like his; the patient journeyed to Inverness full of hope, and, finding no doctor of the name there, came back to London full of rage, but cured withal of his complaint. Of a piece with this is his famous advice to Sir Richard Blackmore. When Blackmore first engaged in the study of physic he inquired of Dr Sydenham what authors he should read, and was directed by that physician to *Don Quixote*, "which," said he, "is a very good book; I read it still." There were cases, he tells us, in his practice where "I have consulted my patient's safety and my own reputation most effectually by doing nothing at all." It was in the treatment of small-pox that his startling innovations in that direction made most stir. It would be a mistake, however, to suppose that Sydenham wrote no long prescriptions, after the fashion of the time, or was entirely free from theoretical bias. Doctrines of disease he had, as every practitioner must have; but he was too much alive to the multiplicity of new facts and to the infinite variety of individual constitutions to aim at symmetry in his theoretical views or at consistency between his practice and his doctrines; and his treatment was what he found to answer best, whether it were *secundum artem* or not. His fundamental idea was to take diseases as they presented themselves in nature and to draw up a complete picture ("Krankheitsbild" of the Germans) of the objective characters of each. Most forms of ill-health, he insisted, had a definite type, comparable to the types of animal and vegetable species. The conformity of type in the symptoms and course of a malady was due to the uniformity of the cause. The causes that he dwelt upon were the "evident and conjunct causes," or, in other words, the morbid phenomena; the remote causes he thought it vain to seek after. Acute diseases, such as fevers and inflammations, he regarded as a wholesome conservative effort or reaction of the organism to meet the blow of some injurious influence operating from without; in this he followed the Hippocratic teaching closely as well as the Hippocratic practice of watching and aiding the natural crises. Chronic diseases, on the other hand, were a depraved state of the humours, mostly due to errors of diet and general manner of life, for which we ourselves were directly accountable. Hence his famous dictum: "*acutos* dico, qui ut plurimum Deum habent authorem, sicut chronici ipsos nos." Sydenham's nosological method is essentially the modern one, except that it wanted the morbid anatomy part, which was first introduced into the "natural history of disease" by Morgagni nearly a century later. In both departments of nosology, the acute and the chronic, Sydenham contributed largely to the natural history by his own accurate observation and philosophical comparison of case with case and type with type. The *Observationes medicae* and the first *Epistola responsoria* contain evidence of a close study of the various fevers, fluxes and other acute maladies of London over a series of years, their differences from year to year and from season to season, together with references to the prevailing weather—the whole body of observations being used to illustrate the doctrine of the "epidemic constitution" of the year or season, which he considered to depend often upon inscrutable telluric causes. The type of the acute disease varied, he found, according to the year and season, and the right treatment could not be adopted until the type was known. There had been nothing quite like this in medical literature since the Hippocratic treatise, Περὶ ἀέρων, ὑδάτων, τόπων; and there are probably some germs of truth in it still undeveloped, although the modern science of epidemiology has introduced a whole new set of considerations. Among other things Sydenham is credited with the first diagnosis of scarlatina and with the modern definition of chorea (in *Sched. monit.*). After small-pox, the diseases to which he refers most are hysteria and gout, his description of the latter (from the symptoms in his own person) being one of the classical pieces of medical writing. While Sydenham's "natural history" method has doubtless been the chief ground of his great posthumous fame, there can be no question that another reason for the admiration of posterity was that which is indicated by R. G. Latham, when he says, "I believe that the moral element of a liberal and candid spirit went hand in hand with the intellectual qualifications of observation, analysis and comparison."

Among the lives of Sydenham are one (anonymous) by Samuel Johnson in John Swan's translation of his works (London, 1742), another by C. G. Kühn in his edition of his works (Leipzig, 1827), and a third by Dr R. G. Latham in his translation of his works published in London by the Sydenham Society in 1848. See also Frédéric Picard, *Sydenham, sa vie, ses œuvres* (Paris, 1889), and J. F. Payne, *T. Sydenham* (London, 1900). Dr John Brown's "Locke and Sydenham," in *Horae subsecivae* (Edinburgh, 1858), is of the nature of eulogy. Many collected editions of his works have been published, as well as translations into English, German, French and Italian. Dr W. A. Greenhill's Latin text (London, 1844, Syd. Soc.) is a model of editing and indexing. The most interesting summary of doctrine and practice by the author himself is the introduction to the 3rd edition of *Observationes medicae* (1676).

SYDENHAM, a large residential district in the south of London, England, partly within the metropolitan borough of Lewisham (*q.v.*). The Crystal Palace (*q.v.*) is in this district.

SYDNEY, the capital of New South Wales, Australia, in Cumberland county, on the east coast of the continent, situated on the south shore of Port Jackson (*q.v.*), in 33° 15′ 44″ S., 151° 12′ 23″ E. Few capitals in the world can rival Sydney in natural advantages and beauty of site. It stands on undulating and easily drained ground, upon a bed of sandstone rock, on a peninsula jutting into one of the deepest, safest and most beautiful harbours in the world; and in addition it lies in the centre of a great carboniferous area. The metropolitan area of Sydney consists of a peninsula, about 13 m. in length, lying between the Parramatta and George's rivers. The sea frontage of this area stretches for 12 m. from the South Head of Port Jackson to the North Head of Botany Bay; it consists of bold cliffs alternating with beautiful beaches, of which some are connected with the city by tramway, and form favourite places of resort. The city proper occupies two indented tongues of land, having a water frontage on Port Jackson, and extending from Rushcutter's Bay on the east to Blackwattle Bay on the west, a distance of 8 m., nearly two miles of which is occupied by the Domain and the botanical gardens. The business quarter is a limited area lying between Darling Harbour and the Domain. The streets are irregular in width, some of them narrow and close together, while those leading down to Darling Harbour have a steep incline. Sydney has in consequence more than usually the appearance of an old-world town.

The main street of the city, George Street, is 2 m. long, running from north to south; it contains the town-hall, the post office and the Anglican cathedral. The post office is a handsome sandstone building in Renaissance style; it is colonnaded on two sides with polished granite columns and surmounted by a clock tower, containing a peal of bells. The town-hall, a large

[1] See Dr John Brown's *Horae subsecivae*, art. "Dr Andrew Brown and Sydenham."

Emery Walker sc.

florid building of Classic order, stands on an eminence, and its clock tower forms a landmark; it contains the spacious Centennial Hall (commemorating the first Australian colonization here in 1787), and has one of the finest organs in the world. Opposite are the Queen Victoria Markets, a striking Byzantine erection, capped by numerous turrets and domes. Adjoining the town hall is the Anglican cathedral of St Andrew, in the Perpendicular style; it has two towers at the west end and a low central tower above the intersection of the nave and transepts, with a very handsome chapter house. Second in importance to George Street is Pitt Street, which runs parallel to it from the Circular Quay to the railway station; Macquarie Street runs alongside the Domain and contains a number of public buildings, including the treasury, the office of public works, the houses of parliament and the mint. In Bridge Street, behind the office of public works, are the exchange and the crown lands office. All these government offices are in classical style. The Roman Catholic Cathedral of St Mary lies on the north-east side of Hyde Park; it is a splendid Gothic structure, the finest in Australia. This cathedral has been twice destroyed by fire, and the existing building, from the designs of Mr W. W. Wardell, was consecrated in 1905. Government House, the residence of the governor-general, an excellent Tudor building erected in 1837, and several times enlarged, is delightfully situated in the Domain, overlooking Farm Cove. The residence of the state governor is at Rose Bay, east of the city. At the top of King Street there is a statue of Queen Victoria and close by a statue of Prince Albert, at the entrance to Hyde Park, in which the most elevated spot is occupied by a statue of Captain Cook. The university stands in its own grounds on the site of Grose Farm, the scene of one of the earliest attempts at government farming. Like most of the buildings at Sydney, the university is built of the excellent sandstone from the quarries of Pyrmont; it is 15th-century Gothic in style and stands at the top of a gentle slope, surrounded by gardens. Around it lie three Gothic colleges in the 14th-century style, affiliated to the university and known as St Paul's, St John's and St Andrew's. They are residential colleges belonging respectively to the Anglicans, Roman Catholics and Presbyterians. The university provides instruction and grants degrees in arts, law, medicine, science and engineering; instruction in theology, however, is given, not by the university, but by the different affiliated colleges.

To compensate for the narrowness of its streets and its lack of fine promenades Sydney possesses a number of grand parks, surpassed in few other capitals. Hyde Park is a plateau almost in the centre of the city, which in the early days of Sydney was used as a race-course. Adjoining are two smaller parks, Cook Park and Philip Park, while north of these stretches the Domain and the botanical gardens. The Domain embraces 138 acres, extending along one side of Woolloomooloo Bay and surrounding Farm Cove, in which the warships belonging to the Australian station are usually anchored; in this charming expanse of park land are the governor's residence and the National Art Gallery, which houses a splendid collection of pictures by modern artists, statuary, pottery and other objects of art. The botanical gardens on the southern shores of Farm Cove are the finest in the Commonwealth and are distinguished for their immense collection of exotics. On the south-east of the city lie Moore Park, 600 acres in extent, containing two fine cricket grounds and the show grounds of the agricultural society, and Centennial Park, formerly a water reserve of 768 acres. Adjoining Moore Park is the metropolitan race-course of Randwick. There are numerous other and smaller parks, of which the chief are Wentworth Park laid out on the site of Blackwattle Swamp, Prince Alfred Park, Belmore Park and Victoria Park adjoining the university grounds.

Sydney harbour is divided into a number of inlets by projecting headlands. The head of Woolloomooloo Bay, Sydney Cove, the shallow bay between Dawes and Millers Point, and Darling Harbour, are lined with wharves. The Circular Quay at the head of Sydney Cove is 1300 ft. long, and here all the great ocean liners from Europe, China and Japan are berthed, while to the great wharf in Woolloomooloo Bay, 3000 ft. in length, the American liners and the majority of the small coasting vessels come to discharge their cargoes. The whole of the eastern side of Darling Harbour is occupied by a succession of wharves and piers, there being in all 4000 ft. of wharfage. Connected with the main railway system of the colony is the Darling Harbour Wharf 1260 ft. long and equipped with electric light, stationary and travelling hydraulic cranes, machinery for meat freezing, and large sheds for storing corn and wool. In addition to these there are wharves at Pyrmont and Blackwattle Bay, respectively 3500 ft. and 1400 ft. long. These harbours on the eastern side of Sydney are mainly frequented by cargo boats trading in coal, corn, frozen meat, wool, hides and various ores. The total length of quays and wharves belonging to the port amounts to some 23 m. The dock accommodation is extensive. On Cockatoo Island, a few miles west of the city, the government have two large dry docks, the Fitzroy dock, 450 ft. long, and the Sutherland dock, 630 ft. Mort's dock, another large dry dock, is at Mort's Bay, Balmain, while there are five floating docks with a combined lifting power of 3895 tons, and the three patent slips in Mort's Bay can raise between them 3040 tons. Prior to 1899 the jurisdiction of the port was in the hands of a marine board, three members of which were elected by the shipping interest, and the remaining four nominated by the government, but in that year the board was replaced by a single official, known as the superintendent of the department of navigation and responsible to the colonial secretary.

Sydney has a great number of learned, educational and charitable institutions; it possesses a Royal Society, a Linnean Society and a Geographical Society, a women's college affiliated to the university, an astronomical observatory, a technical college, a school of art with library attached, a bacteriological institute at Rose Bay, a museum and a free public library. Standing in the centre of a great coal-bearing basin, Sydney is naturally the seat of numerous manufactures, to the prosperity of which the abundance and cheapness of coal has been highly conducive. In addition to the industries connected with the shipping, large numbers of hands are employed in the government railway works, where the locomotives and rolling stock used by the state railways are manufactured. There are several large tobacco factories, flour mills, boot factories, sugar refineries, tanneries, tallow works, meat-preserving, glue and kerosene-oil factories and soap works. Clothing, carriages, pottery, glass, paper and furniture are made, and there are numerous minor industries.

Sydney is governed municipally by a city council. The gas and electric lighting is in the hands of private firms. The administration of the park, the city improvements and the water and sewerage departments have been handed over to boards and trusts. The control of the traffic is in the hands of the police, who, with the wharves and the tramways, are directed by the state government. The whole district between Sydney and Parramatta on each side of the railway is practically one continuous town, the more fashionable suburbs lying on the east of the city while the business extension is to the westward and the southern quarters are largely devoted to manufacturing. The suburbs comprise the following distinct municipalities, Alexandria, with a population in 1901 of 9341; Annandale, 8349; Ashfield, 14,329; Balmain, 30,076; Bexley, 3079; Botany, 3383; North Botany, 3772; Burwood, 7521; Camperdown, 7931; Canterbury, 4226; Concord, 2818; Darlington, 3784; Drummoyne, 4244; Enfield, 2497; Erskineville, 6059; Glebe, 19,220; Hunter's Hill, 4232; Hurstville, 4019; Kogarah, 3892; Lane Cove, 1918; Leichhardt, 17,454; Manly, 5035; Marrickville, 18,775; Eastwood, 713; Mosman, 5691; Newtown, 22,598; North Sydney, 22,040; Paddington, 21,984; Petersham, 15,307; Randwick, 9753; Redfern, 24,219; Rockdale, 7857; Ryde, 3222; St Peter's, 5906; Vaucluse, 1152; Waterloo, 9609; Waverley, 12,342; Willoughby, 6004; Woollahra, 12,351. These suburbs are connected with the city, some by railway, some by steam, cable and electric tramways, and others by ferry across Port Jackson. The tramway system is owned by the government.

There are numerous places of resort for the citizens. Many of the bays in the harbour are largely visited on Sundays and holidays. The most popular resorts are Manly Beach, Chowder Bay and Watson's Bay, in the harbour; Cabarita, on the Parramatta river; Middle Harbour; and Coogee Bay and Bondi, on the ocean beach; Botany, Lady Robinson's Beach, Sandringham and Sans Souci on Botany Bay. Besides these there are two splendid national reserves, an hour's journey by rail from Sydney, viz. National Park, comprising an area of 36,810 acres, surrounding the picturesque bay of Port Hacking; and Kurringai Chase, with an area of 35,300 acres.

The two principal cemeteries are at Waverley and Rookwood. The former is most picturesquely situated on the cliff overlooking the Pacific Ocean.

The climate of Sydney is mild and equable; in summer sea breezes blow from the north-east, which, while they temper the heat, make the air exceedingly humid; in winter the winds blow from the west and the climate is dry and bracing. The mean average temperature is 63° Fahr., and the rainfall 49·66 in.

The population has increased with marvellous rapidity. In 1861 it was (city and suburbs inclusive) 95,000; in 1881, 237,300; in 1891, 399,270; and in 1901, 487,900. The proportion of city dwellers to suburban is as follows: in 1901—city, 112,137; suburbs, 369,693; total, 487,900. The incorporated area of the metropolitan district is about 142 sq. m., or 91,220 acres, so that the average density of population was 5·35 persons per acre, some of the more immediate suburbs being more densely populated than the city itself.

SYDNEY, the chief town of Cape Breton county, Nova Scotia, on a good harbour, the eastern terminus of the Intercolonial railway. Pop. (1891), 2427, (1901), 9900. Formerly a quiet country town, it became between 1891 and 1901 the chief shipping port of the Dominion Coal Company, and the site of the large works of the Dominion Iron and Steel Company. On the opposite side of the harbour are the flourishing towns of North Sydney and of Sydney Mines. It is the starting point for the line of steamers to the Bras d'Or lakes, and a favourite summer resort.

SYENITE, a name first used by Pliny to designate rocks of the same type as the hornblendic granite of Syene (Assouan) in Upper Egypt, so extensively used in ancient times for architectural work and monuments. Transferred by Werner to a rock of much the same appearance, though not identical in mineralogical character with the Egyptian granite, from the Plauen 'scher Grund near Dresden, it is now used as the group name of a class of holo-crystalline plutonic rocks composed essentially of an alkali felspar and a ferromagnesian mineral. The structure and appearance are very much the same as that of a hornblendic granite; from which it is difficult to distinguish these rocks in hand specimens. The important difference, however, is the absence or scarcity of quartz in the syenites. Their essential components are orthoclase, often with some albite, and augite, hornblende or biotite. The orthoclase is white or pink, and forms nearly one half of the rock. It may be veined with albite (microperthite) and small crystals of plagioclase (mostly andesine and oligoclase) often are present, usually having better crystalline forms than the potash felspar. The prevalent hornblende is green, but brown hornblende and dark blue hornblende, of strong pleochroism, occur in some syenites which are rich in alkalis. The augite is usually pale green and may be in perthitic intergrowth with the hornblende. The mica is always of brown colour, as muscovite is not known to occur in these rocks. In the alkali syenites dark green soda augites may be present; other syenites contain a violet augite which has the lamella structure of diallage.

The accessory minerals include sphene (very frequent), apatite, zircon, magnetite and pyrites; quartz as above stated is rarely absent but should never be abundant, otherwise the rock becomes a granite. Nepheline and sodalite occur only in those rocks which show transitions to the nepheline-syenites.

The structure of syenites is almost exactly the same as that of the granites; varieties with porphyritic felspar are known but none of these rocks are evenly granular. The apatite, zircon and magnetite crystallize first, and occur as small well-shaped crystals enclosed in the other minerals. Sphene also is of early formation; then follow augite, biotite and hornblende, the pyroxene usually taking precedence, but regular intergrowths due to simultaneous crystallization of these three minerals are common. The plagioclase felspar succeeds the ferromagnesian minerals, and the alkali felspar is last to crystallize with the exception of the small amount of quartz and of micropegmatite, if these are present. Exceptions to this rule occur, as for example when part of the soda-lime felspar has separated out of the magma before the ferric minerals have ceased to grow, and is consequently enclosed in them in ophitic fashion. Some syenites have a fluxion or even "augen" structure, due to movements during consolidation; orbicular structure may also occur but is very rare.

Although syenites are by no means common rocks and are not of equal importance with granites and diorites from a geological standpoint, they exhibit many varieties which are of interest. Transitional forms between syenite and granite are common as these rocks very frequently occur in the same mass and can hardly be separated from one another in the field. These syenites, comparatively rich in quartz, have been called syenite-granites. Many of the rocks known to the older geologists and shown on the early maps as "syenite" are of this type; others are hornblendic granites in which quartz is not abundant or conspicuous. Another variety of quartz-syenite, very rich in pink alkali felspar (microperthite), is known as nordmarkite; it occurs in Norway, Sweden and Scotland, and contains usually only a small amount of brown biotite and green augite.

The more normal syenites (with only small percentages of quartz) may be divided into augite-, hornblende- and biotite-syenites, according to their prevalent ferric mineral, but usually the rock contains two or even three of the dark-coloured bisilicates. Augite-syenites occur in Saxony and in Norway. In the latter country the most abundant type is laurvikite. These rocks may be red or grey in colour and very largely consist of a perthitic or cryptoperthitic alkali felspar having a beautiful shimmering dull metallic reflection or play of colours. They are coarse-grained rocks, and their great freshness and iridescent appearance when polished make them favourite ornamental stones for facades and pillars. The large felspars have often an elongated elliptical form and are arranged in sub-parallel fashion apparently by fluxion movements. Quartz is usually absent and plagioclase is still more uncommon, but the occasional presence of nepheline and sodalite indicates that these rocks are connected with the nepheline-syenites of the laurvikite type. The ferromagnesian minerals show a great variety and include diopside, aegirine-augite, biotite, brown hornblende, hypersthene and olivine. Zircon is often abundant (zircon-syenite). Rocks very similar to the laurvikites of Norway are known in the Sawtooth Mountains of Texas. These augite-syenites which have plagioclase and orthoclase felspar in nearly equal quantity are called nonzonites. Hornblende-syenites are regarded as being the typical members of the group, hence the best-known syenite, the original rock which Werner described, is of this kind; they are not very common, but occur in Germany, Piedmont and other places, usually with hornblende-granites and diorites. Biotite-syenites also are not frequent, being usually accompanied by granites of which they represent modifications poor in quartz. Most of the rocks formerly known as mica-syenites are now grouped with the lamprophyres as minettes. The following analyses show the chemical composition of a few of the principal types of syenite. They are characterized by a moderate amount of silica, relatively high alkalis (with potash usually preponderating) and alumina, while lime and magnesia are more variable but never in great amount.

(J. S. F.)

	SiO_2.	Al_2O_3.	Fe_2O_3.	FeO.	MgO.	CaO.	Na_2O.	K_2O.
I. Hornblende-syenite (Plauen 'scher Grund, Dresden)	59·83	16·85	—	7·01	2·61	4·43	2·44	6·57
II. Laurvikite (Laurvik, Norway)	58·88	20·30	3·63	2·58	0·79	3·03	5·73	4·50
III. Nordmarkite (Christiania)	59·88	17·87	2·67	1·50	1·04	2·01	7·96	5·69

SYLBURG, FRIEDRICH (1536–1596), German classical scholar, son of a farmer, was born at Wetter near Marburg. He studied at Marburg, Jena, Geneva, and, lastly, Paris, where his teacher was Henry Estienne (Stephanus), to whose great Greek *Thesaurus* Sylburg afterwards made important contributions. Returning to Germany, he held educational posts at Neuhaus near Worms and at Lich near Giessen, where he edited a useful edition of the *Institutiones in graecam linguam* (1580) of Nicolaus Clenardus (Cleynaerts, 1495–1542). In 1583 he resigned his post at Lich and moved to Frankfort-on-the-Main to act as corrector and editor of Greek texts for the enterprising publisher Johann Wechel. To his Frankfort period belong the editions of Pausanias, Herodotus, Dionysius of Halicarnassus (one of his best pieces of work and highly praised by Niebuhr), Aristotle, the Greek and Latin sources for the history of the Roman emperors and the Περὶ συντάξεως of Apollonius Dyscolus. In 1591 he removed to Heidelberg, where he became librarian to the elector palatine. The Wechel series was continued by Hieronymus Commelinus of Heidelberg, for whom Sylburg edited Clement of Alexander, Justin Martyr, the *Etymologicum magnum*, the *Scriptores de re rustica*, the Greek gnomic poets, Xenophon, Nonnus and other works. All Sylburg's editions show great critical power and indefatigable industry. He died on the 17th of February 1596, a victim of over-work.

SYLHET, a town and district of British India, in the Surma valley division of Eastern Bengal and Assam. The town is on the right bank of the river Surma, on rising ground, embowered in groves. Pop. (1901), 13,893. There are manufactures of mats, carved ivory and shells, and furniture. There is an unaided college, founded in 1892, which is mainly supported by a native gentleman. There are two dispensaries and an English church. The great earthquake of the 12th of June 1897 destroyed every substantial building, but caused very little loss of life. Sylhet is the largest town in Assam, but is steadily decaying, being 30 m. from a railway and inaccessible to steamers during the dry season.

The District of Sylhet has an area of 5388 sq. m. It consists of the lower valley of the Surma or Barak river, and for the most part is a uniform level broken only by scattered clusters of sandy hillocks called *tilās*, and intersected by a network of rivers and drainage channels. It is a broad and densely-cultivated plain, except in the extreme north, where the enormous rainfall converts many square miles of land into one huge lake during the rains, and in the south, where eight low ranges of hills, spurs of the Tippera mountains, run out into the plain, the highest range being about 1500 ft. above sea-level. There is also a small detached group in the centre of the district called the Ita hills. The district is watered by the branches of the Surma (*q.v.*) which are navigable by large boats, and support a busy traffic. The climate is extremely damp and the rainfall is heavy, reaching an annual average of over 150 in.; the rainy season generally lasts from April to October.

In 1901 the population was 2,241,848, showing an increase of 4% in the decade. More than half are Mahommedans. Tea cultivation is a flourishing industry in the southern hills. The Assam-Bengal railway crosses the district, but trade is still largely river-borne. Great damage was done by the earthquake of June 1897, which was followed by an outbreak of malarial fever.

Sylhet passed into the hands of the British in 1765, with the rest of Bengal, of which it formed an integral part until 1874, being included in the Dacca division. In that year it was annexed, together with the adjoining district of Cachar, to the chief-commissionership of Assam which was amalgamated with eastern Bengal in 1905.

See *Sylhet District Gazetteer* (Calcutta, 1905).

SYLLABUS (from Gr. συλλαμβάνειν, to take together, cf. "syllable"), literally something taken together, a collection (Late Lat. *syllabus*), hence a compendium, table or abstract giving the heads, outline or scheme of a course of lectures, teaching, &c. The word in the sense of a list or catalogue is used of a collection of eighty condemned propositions, addressed by order of Pius IX. to all the Catholic episcopate, under the date of the 8th of December 1864. The official title is: "A collection (*syllabus*) containing the principal errors of our times as noted in the Allocutions, Encyclicals and other Apostolic Letters of our Holy Father Pope Pius IX." This collection has a rather curious history. As early as 1849, the council of Spoleto asked the pope for a collective condemnation of all errors concerning the Church, her authority and property. In 1851 the *Civiltà cattolica* proposed that this should be drawn up in connexion with the definition of the Immaculate Conception of Mary. In 1852, Cardinal Fornari wrote by order of the pope to a certain number of bishops and laymen asking for their assistance in the study of the errors most prevalent in modern society. The answers are unknown; but after the definition of the Immaculate Conception (December 8, 1854), the commission of theologians charged with the preparatory investigations was entrusted with the further mission of studying modern errors. For six years it gave no outward signs of activity; but in 1860 Mgr Gerbet, bishop of Perpignan, published his *Instruction pastorale sur diverses erreurs du temps présent*; in it he enumerated 85 erroneous propositions, grouped under eleven heads. Pius IX. was much impressed by this work; he had it printed, and communicated it to the commission, to which he added a few new members, desiring them to take it as a fresh basis for their researches. In 1861 the commission had various meetings, at which the principal propositions were chosen and formulated in Latin, and the theological censure which they incurred applied to them. The result was a collection first of 70, and later of 61 propositions, of which only 27 have the note *haeretica*; Mgr Gerbet's divisions, and frequently his text, are adhered to. This Syllabus, which was excellently drawn up, was not promulgated, owing to an indiscretion. On the occasion of the festivals of the canonization of the Japanese martyrs, Pius IX. had gathered around him three hundred bishops from all parts of the world; he had the projected Syllabus communicated to each of them, under the seal of secrecy for the purpose of asking their opinion on it; each bishop was also, still under the seal of secrecy, empowered to consult a theologian selected by himself. But in October 1862, the Turin *Mediatore* published the catalogue in full, and Mgr Bourget, bishop of Montreal, thinking that it had been published in Rome, officially promulgated it for his diocese in December 1863. Pius IX. then modified his plans: a new commission was appointed to extract from the Allocutions, Encyclicals and papal Letters the chief errors dealt with in them. This work lasted about a year; the result of it was the Syllabus, in eighty propositions, arranged under the distinct heads; the propositions are not accompanied by any theological censure, but simply by a reference to the Allocution, Encyclical or Letter from which each had been more or less textually extracted. This was addressed to the episcopate together with a letter from Cardinal Antonelli, and dated the 8th of December 1864, the same date as the Encyclical *Quanta cura*, from which, however, it remains quite distinct. Its publication aroused the most violent polemics; what was then called the Ultramontane party was loud in its praise; while the liberals treated it as a declaration of war made by the Church on modern society and civilization. Napoleon III.'s government forbade its publication, and suspended the newspaper *l'Univers* for having published it. Controversies were equally numerous as to the theological value of the Syllabus. Most Catholics saw in it as many infallible definitions as condemned propositions; others observed that the pope had neither personally signed nor promulgated the collection, but had intentionally separated it from the Encyclical by sending it merely under cover of a letter from his secretary of state; they said that it was hastily, and sometimes unfortunately drawn up (cf. prop. 61); they saw in it an act of the pontifical authority, but without any of the marks required in the case of dogmatic definitions; they concluded, therefore, that each proposition was to be appreciated separately, and in consequence that each was open to theological comment. That such is the true view is proved by the fact that Rome never censured the theologians who, like Newman, took up this position.

The errors enumerated in the Syllabus are grouped under the ten following heads: (1) Pantheism, naturalism and absolute rationalism; (2) Moderate rationalism; (3) Indifferentism, latitudinarianism; (4) Socialism, communism, secret societies, Bible societies, clerico-liberal societies; (5) Errors regarding the Church and her rights; (6) Errors regarding civil society both in itself and in its relations with the Church; (7) Errors regarding Christian and natural morality; (8) Errors regarding Christian marriage; (9) Errors concerning the temporal power of the pope; (10) Errors relative to modern Liberalism. It was paragraphs 5, 6 and 10 which especially gave rise to discussion. In reality, however, the Syllabus did not contain a new doctrine: the Church was defending her traditional doctrine against the progressive invasion of what were called modern ideas of liberty, *i.e.* the independence of religious authority shown by secular societies, liberty of conscience, equality of all religious confessions before the state, &c. She upheld her theoretical position as in the time of Philip the Fair or of the Reformation, and the Syllabus goes no further in this respect than the Encyclical *Quanta cura* of the same date, or that of Gregory XVI., *Mirari vos*, of the 15th of August 1832. But the unusual form of the document should be considered: instead of an exposition of doctrine it enumerates the errors in the form of bare propositions, without any qualification, and with no variation in the degree of condemnation; the result being that many people on both sides were misled.

The name Syllabus has sometimes also been given to the collection of 65 "modernist" propositions condemned by the decree *Lamentabili* of the Holy Office, dated the 3rd of July 1907; but this name is in no wise official.

Bibliography.—The documents from which the propositions of the Syllabus were borrowed have been collected together in the *Recueil des allocutions consistoriales, &c. citées dans l'encyclique et le syllabus* (Paris, 1865). For the history of the Syllabus: P. Hourat, *Le Syllabus, étude documentaire* (Paris, 1904); and P. Rinaldi, *Il Valore del sillabo* (Rome, 1888). For its theological value: Newman, *A Letter Addressed to his Grace the Duke of Norfolk* (London, 1875); P. Viollet, *L'Infallibilité du pape et le syllabus* (Paris, 1904); L. Choupin, *Valeur des décisions doctrinales et disciplinaires du Saint Siège* (Paris, 1907). See also Mgr. Dupanloup, *La Convention du 15 septembre et l'encyclique du 8 décembre* (Paris, 1865); and for the opposite view, see Trarieux, *Le Syllabus et la déclaration des droits de l'homme* (Paris, 1902). (A. Bo.*)

SYLLOGISM (Gr. συλλογισμός, from σύν, and λόγος, an argument resulting from combination, *i.e.* of premises), in logic, an argument consisting of premises and a conclusion. Aristotle's definition is (*Anal. Pr.* α i. 24 b 18; cf. Top. α i. 100 a 25): συλλογισμὸς ἐστι λόγος ἐν ᾧ τεθέντων τίνων ἕτερόν τι τῶν κειμένων ἐξ ἀνάγκης συμβαίνει τῷ ταῦτα εἶναι, "a syllogism is an argument in which, certain things being posited (the premises), something other than the premises necessarily results from their being true." This definition, though it contains the really important facts, is too wide in two respects. (1) Aristotle himself and subsequent logicians restrict the term to arguments in which there are but two premises. (2) In point of fact, all logicians further confine the syllogism to arguments in which the terms are related as subject and predicate (or attribute in the widest sense). A fortiori arguments, for example, wherein relations of quantity are brought together, though syllogistic in type, are generally excluded. Owing largely to the simplicity and symmetry of the syllogism it has been a commonplace of logic to make the syllogistic form the type of all thought. Modern logicians (cf. especially F. H. Bradley in his *Logic*) have, however, shown that in practice its importance is greatly exaggerated.

A. *The Deductive Syllogism.*—This argument is the simplest form of "mediate" inference, *i.e.* an argument in which two terms are brought into a necessary relation by the aid of a "middle" term which serves as a bridge. It requires, therefore, two propositions known as premises [1] (also spelled premisses, as being more in accordance with the Lat. *praemissae* [*propositiones sententiae*], things put or posited in advance) which contain one common term and one other term each. In the conclusion the middle term disappears and the other two are brought together. The premises are assumed: whether true or false, the conclusion follows necessarily. If the premises are true, the conclusion must be true: if they are false the great probability is that the conclusion is false. The predicate of the conclusion is called the *major* term, the subject the *minor* term; the term which is common to the premises and disappears in the conclusion is the *middle* term. Hence the premise which contains the major term is called the major premise: that which contains the minor, the minor premise. The form of the syllogism is therefore:—

A is B	Major premise
C is A	Minor "
∴ C is B	Conclusion

Syllogisms differ in (*a*) "figure" and (*b*) "mood." (*a*) Difference of figure depends on the order of the terms in the premises. The above is the scheme of figure I. If the middle term is the predicate in both premises, the syllogism is in figure II.: if the subject in both, figure III. These are the only figures recognized by Aristotle, though he points out that the premises in figure I. may justify a conclusion in which the predicate is not, as normally, the major term, but the minor. This possibility, according to Averroes, led to the adoption by the physician Galen of the so-called fourth figure, in which the middle term is predicate of the major and subject of the minor. This, however, destroys the appropriateness of the phrases major and minor term which are specially chosen because in fact the major term does imply the more comprehensive notion. The conclusion is an artificial proposition which would be stated naturally in the converse.

b. The distinction of moods is according to the quantity or quality of the propositions of the syllogism (universal, particular, affirmative, negative, in all the possible combinations). So far as mere form goes, each mood may occur in every figure, though in many cases the conclusion apparently yielded from the premises is invalid. A simple calculation shows that formally there are 64 possible moods. Investigation shows that of these nineteen [2] only are valid, and rules have been formulated which give the reasons for the invalidity of the remaining 45.

The rules which govern syllogistic arguments thus described are:—

i. A syllogism must contain three and three terms only. (*a*) Four terms would mean the absence of any connecting link. (*b*) If the middle term is ambiguous there are really four not three terms. The violation of (*a*) is the fallacy "Quaternio terminorum"; of (*b*) "ambiguous middle."

ii. The middle term must be distributed in one premise at least, *i.e.* it must be taken universally, as including all the particulars over which it extends (see Extension). Violation of this is the fallacy of "undistributed middle."

iii. No inference can be made from two negative premises.

iv. If either premise is negative, the conclusion is negative.

v. The conclusion cannot be negative, if both premises are affirmative.

vi. No term may be distributed in this conclusion which was not distributed in the premise in which it occurs. Violation of this rule is called an "illicit process of the major (or the minor) term."

vii. From two particular premises nothing can be inferred.[3]

viii. If either premise is particular, the conclusion must be particular.[3]

[1] Aristotle προτάσεις, originally translated *propositiones*; *praemissae* dates from 12th century Latin translations of Arabic versions of Aristotle. The term "premises" (a house, &c.), is derived loosely from the legal phase denoting that which has already been mentioned in a document, and is etymologically the same.

[2] The following mnemonic hexameter verses are generally given (first apparently in Aldrich's *Artis logicae rudimenta*) to aid in remembering these moods. The vowels in the words, A, E, I, O, show the quantity and quality of the premises:—

Barbara Celarent Darii Ferioque prioris;
Cesare Camestres Festino Baroco secundi;
Tertia Darapti Disamis Datisi Felapton
Bocardo Ferison habet: quarta insuper addit
Bramantip Camenes Dimaris Fesapo Fresison.

[3] These latter are corollaries of previous rules.

The general criticism of the syllogism as a means of discovering truth is that it is a *petitio principii*, or begging of the question. This accusation is based to some extent on the Aristotelian "Dictum de omni et nullo" (*Anal. Pri.* α i. 24, b 26–30), generally stated as "That which is affirmed or denied of any whole may be affirmed or denied of anything contained within (or 'any part of') that whole." To take a concrete instance of a valid mood: all men are mortal, all Frenchmen are men, therefore all Frenchmen are mortal (the mood Barbara). It is argued that either there is here no real discovery (*i.e.* new truth) or the major premise is improperly used (begs the question) inasmuch as unless we knew that all Frenchmen are mortal we could not state that all *men* are mortal. The problem raised is a real one, and has been discussed by all logicians, from the time of Mill especially. In brief, the solution depends upon the view we take of the major premise, "all men are mortal." If that judgment is taken as a mere enumeration of particulars, *i.e.* in extension, as meaning that all men have been investigated and found to be mortal, clearly it could not be used to make the new discovery that a particular group of men are mortal; the syllogism so understood is a *petitio principii*. If, however, we take the true view of the major premise, namely, that it is not a mere summary of observed particulars but the enunciation of a necessary connexion between two concepts or universals, then the conclusion assumes a different character. The "whole" (*omne*) of the dictum, the major term, ceases to be taken in extension, and becomes intensive or connotative, and the inference consists in subsuming the minor under (bringing it into connexion with) the major. This is the true view of the scientific or inductive universal (as opposed to that of nominalism or pure empiricism). It remains true that in fact the conclusion is contained in the premises—this is essential to the validity of the syllogism—but the inference is a real one because it brings out and shows the necessity of a conclusion which was not before in our minds.

Hypothetical and Disjunctive Syllogisms.—The term syllogism has been extended to cover certain forms of ratiocination which are not based on categorical propositions. The propriety of this extended use is open to question and is denied by some logicians.

a. Hypothetical "Syllogisms" are those in which one premise is a hypothetical proposition, the other a categorical. Two forms are possible (i.) *modus ponens* (which establishes the consequent set down in the major premise): if A is B, it is C (or C is D); A is B; therefore A is C (or C is D), and (ii.) *modus tollens* (which disproves the antecedent): if A is B, it is C (or C is D); A is not C (or C is not D); therefore it is not B (or A is not B). In (i.) a valid conclusion follows from the affirmation of the antecedent: in (ii.) from denying the consequent, but in neither case conversely. The distinction is of greater importance than would appear when one realizes how obvious the facts really are, and in practice it happens frequently that speakers claim with success to disprove a proposition by disproving the fact alleged in support of it, or to establish a hypothesis by showing that facts agree with its consequences.

b. Disjunctive "Syllogisms" are those in which one premise is a disjunctive proposition, the other a categorical proposition which states or denies one of the two alternatives set forth. Again two forms occur: (i.) *modus ponendo tollens* which by the affirmation of one alternative denies the other (A is either B or C; A is B; therefore it is not C: *or* either A is B, or C is D; A is B; therefore C is not D: *or* either A or B is C; A is C; therefore B is not C); (ii.) *modus tollendo ponens* which by the denial of the one, establishes the validity of the other alternative (A is either B or C; A is not B; therefore it is C: *or* either A or B is C; A is not C; therefore B is C: *or* either A is B, or C is D; A is not B; therefore C is D). The validity of such arguments depends upon the sense in which we understand the disjunctive proposition: we must assume that the alternatives are mutually exclusive.[1]

Sorites.—Finally it is necessary to mention a complex syllogistic argument known as the *Sorites* (Gr. σωρός, heap). It has been defined as a syllogism in Fig. 1 (see above) having many middle terms; it is really a series of syllogisms (a polysyllogism), each one proving a premise of another, the intermediate conclusions being suppressed. Its form is A is B, B is C, C is D . . . . Y is Z, therefore A is Z. Each syllogism of the series is called a "prosyllogism"[2] in relation to the one that succeeds, and an "episyllogism" in relation to its predecessors. Resolution of the sorites into its constituent elements gives the rules (α) that no premise except the first may be particular and (β) that no premise except the last may be negative.

B. *The Inductive Syllogism*, like the deductive, is first systematized by Aristotle, who described it as ὁ ἐξ ἐπαγωγῆς συλλογισμός. Unlike the deductive it consists in establishing a conclusion from particular premises, *i.e.* of referring the major term to the middle by means of the minor. The form is "A B C D, &c., are P; A B C D are all M; thus all M are P." This so-called syllogism has been much criticized by modern logicians on various grounds (see LOGIC).

Discussions of the syllogism will be found in all textbooks on Logic, and the more elaborate syllogistic forms are discussed in the article LOGIC.

[1] For a dilemma which includes both hypothetical and disjunctive reasoning see DILEMMA.

[2] Where one premise of a prosyllogism is omitted (see ENTHYMEME), this argument is sometimes called an "epicheirema."

SYLPH, an imaginary spirit of the air; according to Paracelsus, the first modern writer who uses the word, an air-elemental, coming between material and immaterial beings. In current usage, the term is applied to a feminine spirit or fairy, and is often used in a figurative sense of a graceful, slender girl or young woman. The form of the word points to a Greek origin, and Aristotle's σίλφη, a kind of beetle (*Hist. anim.* 8. 17. 8), has usually been taken as the source. Similarly, the earth-elementals or earth-spirits were in Paracelsus's nomenclature, "gnomes" (Gr. γνώμη, intelligence, γιγνώσκειν, to know) as being the spirits that gave the secrets of the earth to mortals. Littré, however, takes the word to be Old Celtic, and meaning "genius," and states that it occurs in such forms as *sulfi*, *sylfi*, &c., in inscriptions, or latinized as *sulevae* or *suleviae*.

SYLT (probably from the O. Fris. *Silendi*, *i.e.* sealand), the largest German island in the North Sea, being about 38 sq. m. in area and nearly 23 m. long. It is, however, very narrow, being generally about half a mile in width, except in the middle, where it sends out a peninsula to the east 7 m. across. It belongs to the Prussian province of Schleswig-Holstein, and lies from 7 to 12 m. from the Schleswig coast. The central peninsula contains some marshland and moorland pasture, on which a few thousand sheep graze; but the rest of the island consists merely of dunes or sandhills. These attain at places a height of from 100 to 150 ft., and are continually shifting to the westward. The inhabitants (3500) are of Frisian origin, and the official language is German, though in the extreme north of the island, known as List, Danish is spoken. Their occupations are fishing, oyster-dredging, seafaring and wild-duck catching. The chief places are Keitum, Tinnum, Morsum, Rantum and Westerland. Westerland, one of the most frequented sea-bathing places of Germany, lies on the west side of the island, separated from the sea, which is seldom perfectly calm, by a chain of sand dunes, across which board walks lead to the beach. The island is reached by a regular steamboat service from Hoyer on the mainland to Munkmarsch, which is connected by a steam tram with Westerland. Another line of steamers runs from Hamburg to Sylt via Heligoland. During the Danish War of 1864, after suffering severely at the hands of the Danes, the island was occupied by the Prussians on the 13th of July (see FRISIAN ISLANDS).

See P. Knuth, *Botanische Wanderungen auf der Insel Sylt* (Tondern, 1890); C. P. Hansen, *Das Nordseebad Westerland auf Sylt* (Garding, 1891); Meyn, *Geologische Beschreibung der Insel Sylt* (Berlin, 1876); and Kepp, *Wegweiser auf Sylt* (Tondern, 1885).

SYLVANITE, a mineral consisting of gold and silver telluride, $AuAgTe_4$, containing gold 24·2 and silver 13·3 %; an important ore of gold. Crystals are monoclinic and often very rich in faces; they are frequently twinned, giving rise to branching forms resembling written characters; on this account the mineral was early known as "graphic gold" or "graphic tellurium" (Ger. *Schrifterz*). It was also known as "white gold," the colour being tin-white with a brilliant metallic lustre. The hardness is 2 and the specific gravity 8·2. It occurs with native gold in veins traversing porphyry at Offenbánya and Nagyág, near Déva in Transylvania (from which country it takes its name); also at several places in Boulder county, Colorado, and at Kalgoorlie in Western Australia. Sylvanite may be readily distinguished from calaverite ($AuTe_2$) by its perfect cleavage in one direction (parallel to the plane of symmetry), but in this character it resembles the very rare orthorhombic mineral krennerite ($[Au, Ag]Te_2$). (L. J. S.)

SYLVESTER, JAMES JOSEPH (1814–1897), English mathematician, was born in London on the 3rd of September 1814. He went to school first at Highgate and then at Liverpool, and in 1831 entered St John's College, Cambridge. In his Tripos examination, which through illness he was prevented from taking till 1837, he was placed as second wrangler, but being a Jew and unwilling to sign the Thirty-nine Articles, he could not compete for one of the Smith's prizes and was ineligible for a fellowship, nor could he even take a degree: this last, however, he obtained at Trinity College, Dublin, where religious restrictions were no longer in force. After leaving Cambridge he was appointed to the chair of natural philosophy at University College, London, where his friend A. De Morgan was one of his colleagues, but he resigned in 1840 in order to become professor of mathematics in the university of Virginia. There, however, he remained only six months, for certain views on slavery, strongly held and injudiciously expressed, entailed unpleasant consequences, and necessitated his return to England, where he obtained in 1844 the post of actuary to the Legal and Equitable Life Assurance Company. In the course of the ensuing ten years he published a large amount of original work, much of it dealing with the theory of invariants, which marked him as one of the foremost mathematicians of the time. But he failed to obtain either of two posts—the professorships of mathematics at the Royal Military Academy and of geometry in Gresham College—for which he applied in 1854, though he was elected to the former in the following year on the death of his successful competitor. At Woolwich he remained until 1870, and although he was not a great success as an elementary teacher, that period of his life was very rich in mathematical work, which included remarkable advances in the theory of the partition of numbers and further contributions to that of invariants, together with an important research which yielded a proof, hitherto lacking, of Newton's rule for the discovery of imaginary roots for algebraical equations up to and including the fifth degree. In 1874 he produced several papers suggested by A. Peaucellier's discovery of the straight line link motion associated with his name, and he also invented the skew pentagraph. Three years later he was appointed professor of mathematics in the Johns Hopkins University, Baltimore, stipulating for an annual salary of $5000, to be paid in gold. At Baltimore he gave an enormous impetus to the study of the higher mathematics in America, and during the time he was there he contributed to the *American Journal of Mathematics*, of which he was the first editor, no less than thirty papers, some of great length, dealing mainly with modern algebra, the theory of numbers, theory of partitions and universal algebra. In 1883 he was chosen to succeed Henry Smith in the Savilian chair of geometry at Oxford, and there he produced his theory of reciprocants, largely by the aid of his "method of infinitesimal variation." In 1893 loss of health and failing eyesight obliged him to give up the active duties of his chair, and a deputy professor being appointed, he went to live in London, where he died on the 15th of March 1897. Sylvester's work suffered from a certain lack of steadiness and method in his character. For long periods he was mathematically unproductive, but then sudden inspiration would come upon him and his ideas and theories poured forth far more quickly than he could record them. All the same his output of work was as large as it was valuable. The scope of his researches was described by Arthur Cayley, his friend and fellow worker, in the following words: "They relate chiefly to finite analysis, and cover by their subjects a large part of it—algebra, determinants, elimination, the theory of equations, partitions, tactic, the theory of forms, matrices, reciprocants, the Hamiltonian numbers, &c.; analytical and pure geometry occupy a less prominent position; and mechanics, optics and astronomy are not absent." Sylvester was a good linguist, and a diligent composer of verse, both in English and Latin, but the opinion he cherished that his poems were on a level with his mathematical achievements has not met with general acceptance.

The first volume of his *Collected Mathematical Papers*, edited by H. F. Baker, appeared in 1904.

SYLVESTER, JOSHUA (1563–1618), English poet, the son of a Kentish clothier, was born in 1563. In his tenth year he was sent to school at Southampton, where he gained a knowledge of French. After about three years at school he appears to have been put to business, and in 1591 the title-page of his *Yvry* states that he was in the service of the Merchant Adventurers' Company. He was for a short time a land steward, and in 1606 Prince Henry gave him a small pension as a kind of court poet. In 1613 he obtained a position as secretary to the Merchant Adventurers. He was stationed at Middelburg, in the Low Countries, where he died on the 28th of September 1618. He translated into English heroic couplets the scriptural epic of Guillaume du Bartas. His *Essay of the Second Week* was published in 1598; and in 1604 *The Divine Weeks of the World's Birth*. The ornate style of the original offered no difficulty to Sylvester, who was himself a disciple of the Euphuists and added many adornments of his own invention. The *Sepmaines* of Du Bartas appealed most to his English and German co-religionists, and the translation was immensely popular. It has often been suggested that Milton owed something in the conception of *Paradise Lost* to Sylvester's translation. His popularity ceased with the Restoration, and Dryden called his verse "abominable fustian."

His works were reprinted by Dr A. B. Grosart (1880) in the "Chertsey Worthies Library." See also C. Dunster's *Considerations on Milton's early Reading* (1800).

SYLVITE, a mineral consisting of potassium chloride (KCl), first observed in 1823, as an encrustation on Vesuvian lava. Well-formed crystals were subsequently found in the salt deposits of Stassfurt in Prussia and Kalusz in Austrian Galicia. It crystallizes in the cubic system with the form of cubes and cubo-octahedra and possesses perfect cleavages parallel to the faces of the cube. Although the crystals are very similar in appearance to crystals of common salt, they are proved by etching experiments to possess a different degree of symmetry, namely plagihedral-cubic, there being no planes of symmetry but the full number of axes of symmetry. Crystals are colourless (sometimes bright blue) and transparent; the hardness is 2 and the specific gravity 1·98. Like salt, it is highly diathermanous. The name sylvite or sylvine is from the old pharmaceutical name, *sal digestivus sylvii*, for this salt. (L. J. S.)

SYMBOL (Gr. σύμβολον, a sign), the term given to a visible object representing to the mind the semblance of something which is not shown but realized by association with it. This is conveyed by the ideas usually associated with the symbol; thus the palm branch is the symbol of victory and the anchor of hope. Much of early Christian symbolism owes its origin to pagan sources, the interpretations of the symbols having a different meaning; thus "the Good Shepherd with the lamb" is thought by some to have been derived from the figure of Hermes (Mercury) carrying the goat to sacrifice, and "Orpheus charming the wild beasts," which, when painted in the catacombs, was probably intended as the representation of a type of Christ. One of the earliest symbols of the Saviour, the fish, was derived from an acrostic of the Greek word ἰχθύς, the component letters of which were the initials of the five words Ἰησοῦς Χριστός, Θεοῦ Υἱός, Σώτηρ, Jesus Christ, Son of God, Saviour. The ship, another early symbol, represented the Church in which the faithful are carried over the sea of life. Other symbols are those which were represented by animals, real or fabulous, and were derived from Scripture: thus the lamb typified Christ from St John's Gospel (i. 29 and 36), and the lion from the Book of Revelations, in which Christ is called the "Lion of the tribe of Judah." The peacock stood for immortality; the phoenix for the Resurrection; the dragon or the serpent for Satan; and the stag for the soul thirsting for baptism. The sacred monogram Chi Rho, ☧ supposed to have been the celestial sign seen by the emperor Constantine on the eve of the defeat of Maxentius, represents the two first letters of the Greek word

Χριστός which Constantine figured on his labarum, or standard, and is found on early Christian coins, bearing also the favourite decoration of the Byzantine sarcophagi. The four evangelical symbols are taken from the book of Ezekiel and from the Book of Revelations; thus the winged man is St Matthew, the winged lion St Mark, the winged ox St Luke and the eagle St John; and these four symbols became the favourite subject for representation in the Church. Besides these the other evangelists and the saints carry emblems by which they may be recognized; thus St Andrew by the cross, St Peter by the keys, St Paul by the sword, St Edward by a cup and dagger, St Mary Magdalene by a box or vase, St Lawrence by a gridiron, St Faith also by a gridiron, &c.

SYME, JAMES (1799–1870), Scottish surgeon, was born at Edinburgh on the 7th of November 1799. His father was a writer to the signet and a landowner in Fife and Kinross, who lost most of his fortune in attempting to develop the mineral resources of his property. James was sent to the high school at the age of nine, and remained until he was fifteen, when he entered the university. For two years he frequented the arts classes (including botany), and in 1817 began the medical curriculum, devoting himself with particular keenness to chemistry. His chemical experiments led him to the discovery that "a valuable substance is obtainable from coal tar which has the property of dissolving india-rubber," and could be used for waterproofing silk and other textile fabrics—an idea which was patented a few months afterwards by Charles Mackintosh, of Glasgow. In the session 1818–1819 Syme became assistant and demonstrator of the dissecting room of Robert Liston, who had started as an extra-mural teacher of anatomy in competition with his old master, Dr John Barclay; in those years he held also resident appointments in the infirmary and the fever hospital, and spent some time in Paris practising dissection and operative surgery. In 1823 Liston handed over to him the whole charge of his anatomy classes, retaining his interest in the school as a pecuniary venture; the arrangement did not work smoothly, and a feud with Liston arose, which did not terminate until twenty years later, when the latter was settled in London. In 1824–1825 he started the Brown Square school of medicine, but again disagreed with his partners in the venture. Announcing his intention to practise surgery only, Syme started a surgical hospital of his own, Minto House hospital, which he carried on from May 1829 to September 1833, with great success as a surgical charity and school of clinical instruction. It was here that he first put into practice his method of clinical teaching, which consisted in having the patients to be operated or prelected upon brought from the ward into a lecture-room or theatre where the students were seated conveniently for seeing and taking notes. His private practice had become very considerable, his position having been assured ever since his amputation at the hip joint in 1823, the first operation of the kind in Scotland. In 1833 he succeeded James Russell as professor of clinical surgery in the university. Syme's accession to the clinical chair was marked by two important changes in the conditions of it: the first was that the professor should have the care of surgical patients in the infirmary in right of his professorship, and the second, that attendance on his course should be obligatory on all candidates for the medical degree. When Liston removed to London in 1835 Syme became the leading consulting surgeon in Scotland. On Liston's death in 1847 Syme was offered his vacant chair of clinical surgery at University College, London, and accepted it. He began practice in London in February 1848; but early in May the same year difficulties with two of his colleagues at Gower Street and a desire to "escape from animosity and contention" led him to throw up his appointment. He returned to Edinburgh in July, and was reinstated in his old chair, to which the crown authority had meanwhile found a difficulty in appointing. The judgment of his friends was that "he was always right in the matter, but often wrong in the manner, of his quarrels." In 1849 he broached the subject of medical reform in a letter to the lord advocate; in 1854 and 1857 he addressed open letters on the same subject to Lord Palmerston; and in 1858 a Medical Act was passed which largely followed the lines laid down by himself. As a member of the general medical council called into existence by the act, he made considerable stir in 1868 by an uncompromising statement of doctrines on medical education, which were thought by many to be reactionary; they were, however, merely an attempt to recommend the methods that had been characteristic of Edinburgh teaching since William Cullen's time—namely, a constant reference of facts to principles, the subordination (but not the sacrifice) of technical details to generalities, and the preference of large professional classes and the "magnetism of numbers" to the tutorial system, which he identified with "cramming." In April 1869 he had a paralytic seizure, and at once resigned his chair; he never recovered his powers, and died near Edinburgh on the 26th of June 1870.

Syme's surgical writings were numerous, although the terseness of his style and directness of his method saved them from being bulky. In 1831 he published *A Treatise on the Excision of Diseased Joints* (the celebrated ankle-joint amputation is known by his name). His *Principles of Surgery* (often reprinted) came out a few months later; *Diseases of the Rectum* in 1838; *Stricture of the Urethra and Fistula in Perineo* in 1849; and *Excision of the Scapula* in 1864. In 1848 he collected into a volume, under the title of *Contributions to the Pathology and Practice of Surgery*, thirty-one original memoirs published in periodicals from time to time; and in 1861 he issued another volume of *Observations in Clinical Surgery*. Syme's character is not inaptly summed up in the dedication to him by his old pupil, Dr John Brown, of the series of essays *Locke and Sydenham*: "Verax, capax, perspicax, sagax, efficax, tenax."

See *Memorials of the Life of James Syme*, by R. Paterson, M.D., with portraits (Edinburgh, 1874).

SYMEON METAPHRASTES,[1] the most renowned of the Byzantine hagiographers. Scholars have been very much divided as to the period in which he lived, dates ranging from the 9th century to the 14th having been suggested; but it is now generally agreed that he flourished in the second half of the 10th century. Still greater divergences of opinion have existed as to the lives of saints coming from his pen, and here again the solution of the problem has been attained by studying the composition of the great Greek menologies. The menology of Metaphrastes is a collection of lives of saints for the twelve months of the year, easily recognizable among analogous collections, and consisting of about 150 distinct pieces, some of which are taken bodily from older collections, while others have been subjected to a new recension (μετάφρασις). Among other works attributed (though with some uncertainty) to Symeon are a *Chronicle*, a canonical collection, some letters and poems, and other writings of less importance. Symeon's great popularity is due more particularly to his collection of lives of saints. About his life we know only very few details. The Greeks honour him as a saint on the 28th of November, and an office has been composed in his honour.

See L. Allatius, *De Symeonum scriptis diatriba* (Paris, 1664); F. Hirsch, *Byzantinische Studien*, pp. 303–355 (Leipzig, 1876); A. Ehrhard, *Die Legendensammlung des Symeon Metaphrastes* (Rome, 1897); and in *Römische Quartalschrift* (1897), pp. 67–205 and 531–553; H. Delehaye, *La Vie de S. Paul le jeune et la chronologie de Métaphraste* (1893); *Analecta Bollandiana*, xvi. 312–327 and xvii. 448–452. (H. De.)

SYMMACHUS, pope from 498 to 514, had Anastasius II. for his predecessor and was himself followed by Hormisdas. He was a native of Sardinia, apparently a convert from paganism, and was in deacon's orders at the time of his election. The choice was not unanimous, another candidate, Laurentius, having the support of a strong Byzantine party; and both competitors were consecrated by their friends, the one in the Lateran Church and the other in that of St Mary, on the 22nd of November 498. A decision was not long afterwards obtained in favour of Symmachus from Theodoric, to whom the dispute had been referred; but peace was not established until 505 or 506, when the Gothic king ordered the Laurentian party to surrender the churches of which they had taken possession. An important incident in the protracted controversy was the

[1] The surname is based on the title, *Metaphrasis*, of some of his works.

decision of the "palmary synod." The remainder of the pontificate of Symmachus was uneventful; history speaks of various churches in Rome as having been built or beautified by him.

SYMMACHUS, the name of a celebrated Roman family of the 4th to 6th centuries of our era. It belonged to the gens Aurelia and can be traced back to Aurelius Julianus Symmachus, proconsul of Achaea (according to others, vicar or vice-prefect of Macedonia) in the year 319. Lucius Aurelius Avianius Symmachus, presumably his son, was prefect of Rome in the year 364, and had also other important posts. He was celebrated for his virtues and the senate awarded him in 377 a gilded statue.

QUINTUS AURELIUS SYMMACHUS (*c.* 345–410), son of the last-named, was one of the most brilliant representatives in public life and in the literature of 4th-century paganism in Rome. He was educated in Gaul, and, having discharged the functions of praetor and quaestor, rose to higher offices, and in 373 was proconsul of Africa (for his official career see *C.I.L.* vi. 1699). His public dignities, which included that of pontifex maximus, his great wealth and high character, added to his reputation for eloquence, marked him out as the champion of the pagan senate against the measures which the Christian emperors directed against the old state religion of Rome. In 382 he was banished from Rome by Gratian for his protest against the removal of the statue and altar of Victory from the senate-house (see Gibbon, *Decline and Fall*, ch. 28), and in 384, when he was prefect of the city, he addressed to Valentinian II. a letter praying for the restoration of these symbols. This is the most interesting of his literary remains, and called forth two replies from St Ambrose, as well as a poetical refutation from Prudentius. After this Symmachus was involved in the rebellion of Maximus, but obtained his pardon from Theodosius, and appears to have continued in public life up to his death. In 391 he was Consul ordinarius. His honesty, both in public and in private affairs, and his amiability made him very popular. The only reproach that could be made against this last valiant defender of paganism is a certain aristocratic conservativeness, and an exaggerated love of the past. As his letters do not extend beyond the year 402, he probably died soon after that date.

Of his writings we possess: (1) *Panegyrics*, written in his youth in a very artificial style, two on Valentinian I. and one on the youthful Gratian. (2) Nine books of Epistles, and two from the tenth book, published after his death by his son. The model followed by the writer is Pliny the Younger, and from a reference in the *Saturnalia* of Macrobius (bk. v., i. § 7), in which Symmachus is introduced as one of the interlocutors, it appears that his contemporaries deemed him second to none of the ancients in the "rich and florid" style. We find them vapid and tedious. (3) Fragments of *Complimentary Orations*, five from a palimpsest (also containing the *Panegyrics*), of which part is at Milan and part in the Vatican, discovered by Mai, who published the Milan fragments in 1815, the Roman in his *Scriptorum veterum nova collectio*, vol. i. (1825), and the whole in 1846. (4) The *Relationes*, which contain an interesting account of public life in Rome, composed for the emperor. In these official writings (reports as prefect of the city), Symmachus is not preoccupied by style and becomes sometimes eloquent; especially so in his remarkable report on the altar of Victory.

His son, QUINTUS FABIUS MEMMIUS SYMMACHUS, was proconsul of Africa (415) and prefect of the city (418). He was probably the father of the Symmachus who was consul in 446, and whose son was QUINTUS AURELIUS MEMMIUS SYMMACHUS (d. 525), patrician, one of the most cultivated noblemen of Rome of the beginning of the 6th century, editor (*e.g.* of Macrobius, *Somnium Scipionis*) and historian, and especially celebrated for his building activity. He was consul in 485. Theodoric charged him with the restoration of the theatre of Pompey. He was father-in-law of Boëtius (*q.v.*), and was involved in his fate, being disgraced and finally put to death by Theodoric in 525.

See E. Morin, *Études sur Symmaque* (1847); G. Boissier, *La Fin du paganisme* (1891), vol. ii.; T. R. Glover, *Life and Letters in the Fourth Century* (1901); S. Dill, *Roman Society in the last century of the Western Empire* (1898); T. Hodgkin, *Italy and her Invaders*, (1880–1899) vol. iii. (on the Boëtius "conspiracy"); M. Schanz, *Geschichte der römischen Litteratur* (1904), vol. iv. pt. 1; and Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. trans., 1900), pp. 425, 477, 4. All editions of the works of Symmachus are now superseded by that of O. Seeck in *Monumenta Germaniae historica. Auctores antiquissimi* (1883), vi. 1, with introductions on his life, works and chronology, and a genealogical table of the family.

SYMONDS, JOHN ADDINGTON (1840–1893), English critic and poet, was born at Bristol, on the 5th of October 1840. He was the only son of John Addington Symonds, M.D. (1807–1871), the author of an essay on *Criminal Responsibility* (1869), *The Principles of Beauty* (1857) and *Sleep and Dreams* (2nd ed., 1857). His mother, Harriet Symonds, was the eldest daughter of James Sykes of Leatherhead. He was a delicate boy, and at Harrow, where he was entered in 1854, took no part in school games and showed no particular promise as a scholar. In 1858 he proceeded to Balliol as a commoner, but was elected to an exhibition in the following year. The Oxford training and association with the brilliant set of men then at Balliol called out the latent faculties in Symonds, and his university career was one of continual distinction. In 1860 he took a first in "Mods," and won the Newdigate with a poem on *The Escorial*; in 1862 he was placed in the first class in Literae Humaniores, and in the following year was winner of the Chancellor's English Essay. In 1862 he had been elected to an open fellowship at Magdalen. The strain of study unfortunately proved too great for him, and, immediately after his election to a fellowship, his health broke down, and he was obliged to seek rest in Switzerland. There he met Janet Catherine North, whom, after a romantic betrothal in the mountains, he married at Hastings on the 10th of November 1864. He then attempted to settle in London and study law, but his health again broke down and obliged him to travel. Returning to Clifton, he lectured there, both at the college and to ladies' schools, and the fruits of his work in this direction remain in his *Introduction to the Study of Dante* (1872) and his admirably vivid *Studies of the Greek Poets* (1873–1876). Meanwhile he was occupied upon the work to which his talents and sympathies were especially attracted, his *Renaissance in Italy*, which appeared in seven volumes at intervals between 1875 and 1886. The *Renaissance* had been the subject of Symonds' prize essay at Oxford, and the study which he had then given to the theme aroused in him a desire to produce something like a complete picture of the reawakening of art and literature in Europe. His work, however, was again interrupted by illness, and this time in a more serious form. In 1877 his life was in acute danger, and upon his removal to Davos Platz and subsequent recovery there it was felt that this was the only place where he was likely to be able to enjoy life. From that time onward he practically made his home at Davos, and a charming picture of his life there will be found in *Our Life in the Swiss Highlands* (1891). Symonds, indeed, became in no common sense a citizen of the town; he took part in its municipal business, made friends with the peasants, and shared their interests. There he wrote most of his books: biographies of Shelley (1878), Sir Philip Sidney (1886), Ben Jonson (1886), and Michelangelo (1893), several volumes of poetry and of essays, and a fine translation of the *Autobiography of Benvenuto Cellini* (1887). There, too, he completed his study of the *Renaissance*, the work by which he will be longest remembered. He was assiduously, feverishly active throughout the whole of his life, and the amount of work which he achieved was wonderful when the uncertainty of his health is remembered. He had a passion for Italy, and for many years resided during the autumn in the house of his friend, Horatio F. Brown, on the Zattare, in Venice. He died at Rome on the 19th of April 1893, and was buried close to Shelley.

He left his papers and his autobiography in the hands of Mr Brown, who published in 1895 an excellent and comprehensive biography. Two works from his pen, a volume of essays, *In the Key of Blue*, and a monograph on *Walt Whitman*, were published in the year of his death. His activity was unbroken to the last. In life Symonds was morbidly introspective, a Hamlet among modern men of letters, but with a capacity for action which Hamlet was denied. Robert Louis Stevenson described him, in the Opalstein of *Talks and Talkers*, as "the best of talkers, singing the praises of the earth and the arts, flowers and jewels, wine and music, in a moonlight, serenading manner, as to the light guitar." But under his excellent good-fellowship lurked a haunting melancholy. Full of ardour and ambition, sympathy and desire, he was perpetually tormented by the riddles of existence; through life he was always a seeker, ardent but unsatisfied. This side of his nature stands revealed in his gnomic poetry, and particularly in the sonnets of his *Animi Figura* (1882), where he has portrayed his own character with great subtlety. His poetry is perhaps rather that of the student than of the inspired singer, but it has moments of deep thought and emotion. It is, indeed, in passages and extracts that Symonds appears at his best. Rich in description, full of "purple patches," his work has not that harmony and unity that are essential to the conduct of philosophical argument. He saw the part more clearly than the whole; but his view, if partial, is always vivid and concentrated. His translations are among the finest in the language; here his subject was found for him, and he was able to lavish on it the wealth of colour and quick sympathy which were his characteristics. He was a lover of beauty, a poet and a philosopher; but in his life and his work alike he missed that absolute harmony of conviction and concentration under which alone the highest kind of literature is produced. (A. Wa.)

SYMONDS, WILLIAM SAMUEL (1818–1887), was born in Hereford in 1818. He was educated at Cheltenham and Christ's College, Cambridge, where he graduated B.A. in 1842. Having taken holy orders he was appointed curate of Offenham, near Evesham in 1843, and two years later he was presented to the living of Pendock in Worcestershire, where he remained until 1877. While at Offenham he became acquainted with H. E. Strickland and imbibed from him such an interest in natural history and geology, that his leisure was henceforth devoted to these subjects. He was one of the founders of the Woolhope Naturalists' Field Club (1851) and of the Malvern Naturalists' Field Club (1853), and was an active member of the Cotteswold Field Club and other local societies. In 1858 he edited an edition of Hugh Miller's *Cruise of the "Betsey."* He was the author of numerous essays on the geology of the Malvern country, notably of a paper "On the passage-beds from the Upper Silurian rocks into the Lower Old Red Sandstone at Ledbury" (*Quart. Journ. Geol. Soc.* 1860). His principal work was *Records of the Rocks* (1872). He was author of *Stones of the Valley* (1857), *Old Bones, or Notes for Young Naturalists* (1859, 2nd ed. 1864), and other popular works. He died at Cheltenham on the 15th of September 1887.

See *A Sketch of the Life of the Rev. W. S. Symonds*, by the Rev. J. D. La Touche.

SYMOND'S YAT, one of the most famous view points on the river Wye, England. At a point 9 m. above Monmouth and 12 m. below Ross by water, the Wye makes a sweep of nearly 5 m. round a peninsula whose neck is only some 600 yds. across. The peninsula is occupied by the limestone acclivity of Huntsham Hill. Caverns are seen in the limestone on both precipitous banks of the river. The Yat or Gate is situated on the west side of the neck, which reaches an elevation over 500 ft., and a road from the east drops to a ferry, which was of early importance as a highway between England and Wales. The boundary between Herefordshire and Gloucestershire crosses the neck; the Yat is in the county first named, but the railway station, on the east side (left bank) is in Gloucestershire. It is on the Ross-Monmouth line of the Great Western railway. There are here groups of cottages and several inns on both banks, while opposite the Yat itself is the hamlet of New Weir, and a little above it the village of Whitchurch. The river banks are densely wooded, except where they become sheer cliffs, as at the Coldwell rocks above the station. The surrounding country is hilly and rich, and the views from the Yat are superb, embracing the Forest of Dean to the south and east, and backed by the mountains of the Welsh border in the west.

SYMONS, ARTHUR (1865–), English poet and critic, was born in Wales on the 28th of February 1865, of Cornish parents. He was educated privately, spending much of his time in France and Italy. In 1884-1886 he edited four of Quaritch's *Shakespeare Quarto Facsimiles*, and in 1888–1889 seven plays of the "Henry Irving" Shakespeare. He became a member of the staff of the *Athenaeum* in 1891, and of the *Saturday Review* in 1894. His first volume of verse, *Days and Nights* (1889), consisted of dramatic monologues. His later verse is influenced by a close study of modern French writers, of Baudelaire and especially of Verlaine. He reflects French tendencies both in the subject-matter and style of his poems, in their eroticism and their vividness of description. His volumes of verse are: *Silhouettes* (1892), *London Nights* (1895), *Amoris victima* (1897), *Images of Good and Evil* (1899), *A Book of Twenty Songs* (1905). In 1902 he made a selection from his earlier verse, published as *Poems* (2 vols.). He translated from the Italian of Gabriele d'Annunzio *The Dead City* (1900) and *The Child of Pleasure* (1898), and from the French of Émile Verhaeren *The Dawn* (1898). To *The Poems of Ernest Dowson* (1905) he prefixed an essay on the deceased poet, who was a kind of English Verlaine and had many attractions for Mr Symons. Among his volumes of collected essays are: *Studies in Two Literatures* (1897), *The Symbolist School in Literature* (1899), *Cities* (1903), word-pictures of Rome, Venice, Naples, Seville, &c., *Plays, Acting and Music* (1903), *Studies in Prose and Verse* (1904), *Spiritual Adventures* (1905), *Studies in Seven Arts* (1906).

SYMONS, GEORGE JAMES (1838–1900), English meteorologist, was born in Pimlico, London, on the 6th of August 1838. In 1860 he obtained a post in the meteorological department of the Board of Trade under Admiral Robert Fitzroy, who was then deeply interested in the subject of storm-warnings, and in the same year he published the first annual volume of *British Rainfall*, which contained records from 168 stations in England and Wales, but none from Scotland or Ireland. Three years later he resigned his appointment at the Board of Trade, where his rainfall inquiries were not appreciated—at least not as a prior study of storm-warnings—and devoted his whole energies to the organization of a band of volunteer observers for the collection of particulars of rainfall throughout the British Isles. So successful was he in this object that by 1866 he was able to show results which gave a fair representation of the distribution of rainfall, and the number of recorders gradually increased until the last volume of *British Rainfall* which he lived to edit (that for 1899) contained figures from 3528 stations—2894 in England and Wales, 446 in Scotland, and 188 in Ireland. Apart from their scientific interest, these annual reports are of great practical importance, since they afford engineers and others engaged in water supply much-needed data for their calculations, the former absence of which had on some occasions given rise to grave mistakes. Symons himself devoted special study not only to rainfall, but also to the evaporation and percolation of water as affecting underground streams, and his extensive knowledge rendered him a valuable witness before parliamentary committees. In other branches of meteorology also he took a keen interest, and he was particularly indefatigable, though consistently unsuccessful, in the quest of a genuine thunderbolt. The history of the science too attracted his attention, and he possessed a fine library of meteorological works, which passed to the Meteorological Society at his death. Of that society he became a member when only eighteen, and he retained his connexion with it in various official capacities up to the end of his life. He served as its president in 1880, and in view of the celebration of its jubilee was re-elected to that office in 1900, but the illness that caused his death prevented him from acting. He died in London on the 10th of March 1900.

SYMPATHETIC SYSTEM, in physiology. By the "sympathetic system" is understood a set of nerves and ganglia more or less sharply marked off from the cerebro-spinal, both functionally and anatomically. (For anatomy see NERVOUS SYSTEM.) Formerly it was thought more independent from the rest of the general nervous system than recent discoveries have found it actually to be. It used to be supposed that the ganglia of the sympathetic system were analogous in function to the great central nervous masses forming the brain and spinal cord. These latter masses, as now becomes more and more evident, are the only structures in which occurs the work of transmuting afferent-nerve impulses into efferent-nerve impulses with all the accompanying changes in intensity, rhythm; &c., which make up reflex action. Such functions, it is now known, are not attributable to sympathetic ganglia. These last are structures in which one neurone makes communication with other neurones. To that extent, therefore, redistribution of nervous impulses does occur in them, impulses arriving by a few neurones being distributed so as to affect many. But the sympathetic ganglia are not the seat of reflex action. The sympathetic system is now known to consist entirely of conducting paths which, like the nerve-trunks of the cerebro-spinal system, merely conduct nerve impulses either toward the great nervous centres of the spinal cord and brain, or, on the other hand, away from those great centres. In the cerebro-spinal nerves the preponderance of the conduction is toward the centres, in the sympathetic system the preponderance of conduction is away from the centres.

More is known of the sympathetic system from its efferent aspect than its afferent, and we shall consider the former first. One great difference between the efferent paths of the sympathetic and those of the ordinary cerebro-spinal system is that the former carry nervous impulses not only to muscular tissue but to secreting glands, whereas the latter convey them to muscle only, indeed only to muscle of the striated kind. Another difference is that the efferent path which the sympathetic affords from the great central nervous centres to its muscles and glands consists always of *two* nerve-cells or neurones, whereas the efferent path afforded by the cerebro-spinal motor nerves consists of one neurone only. The two neurones forming the sympathetic path are so arranged that one of them whose cell-body lies in the spinal cord has a long axone-process passing out from the cord in the motor spinal root, and this extends to a group of nerve-cells, a sympathetic ganglion, quite distant from the spinal cord and somewhere on the way to the distant organ which is to be innervated. In this ganglion the first sympathetic neurone ends, forming functional connexion with ganglion cells there. These ganglion cells extend each of them an axone process which attains the organ (muscular cell or gland cell), which it is the office of the sympathetic path to reach and influence. The axone-process of the first nerve cell is a myelinated nerve-fibre extending from the spinal cord to the ganglion; it constitutes the pre-ganglionic fibre of the conduction chain. The axone-process of the second nerve-cell, that is the neurone whose cell-body lies in the ganglion, is usually non-myelinate and constitutes the post-ganglionic fibre of the chain.

This construction, characteristic as it is of the sympathetic efferent path, has been found also in certain other efferent paths outside the sympathetic proper. And as these other efferent paths convey impulses to the same kind of organs and tissues as do those of the sympathetic itself, it has been proposed to embrace them and the sympathetic under one name, the *autonomic* system. This term includes all the efferent paths of the entire body excepting only those leading to the voluntary muscles.

That the term " autonomic system " is not merely a convenience of nomenclature, but really represents a physiological entity, seems indicated by the action of nicotin. This drug acts selectively on the autonomic ganglia and not on the cerebro-spinal. In the former it paralyses the nexus between pre-ganglionic and post-ganglionic fibre. It is by taking advantage of this property that many of the recent researches which have done so much to elucidate the sympathetic have been executed.

The term " autonomic system " must not be taken to imply that this system is independent of the central nervous system. As mentioned above in regard to the sympathetic, that is not the case. The autonomic system is closely connected with the central nervous system through the ordinary channel of the nerve-roots, spinal and cranial. It may, in fact, be regarded as an appendage of the cranial and spinal roots, or rather of certain of them, for with a considerable proportion of their number it is not connected.

The sympathetic is that part of the autonomic system which is connected with the spinal roots from the second thoracic to the second lumbar inclusive (man). Its ganglia are divided by anatomists into the vertebral, those which lie as a double chain on the ventral face of the vertebral column, and those which lie scattered at various distances among the viscera, the pre-vertebral. Langley has shown that there is no essential difference between these except that the vertebral send some of their post-ganglionic fibres into the spinal nerves, whereas the latter send all their fibres to the viscera. The sympathetic sends its post-ganglionic fibres—

1. To the muscular coats of the whole of the alimentary canal from the mouth to the rectum; to the glands opening into the canal from the salivary glands in front back to the intestinal glands; to the blood vessels of the whole of the canal frcm mouth to anus inclusive.

2. To the generative organs, external and internal, and to the muscular coats of the urinary bladder.

3. To the skin; (*a*) to its blood vessels, (*b*) to its cutaneous glands, (*c*) to unstriated muscle in the skin, *e.g.* the erectors of the hairs.

4. To the iris muscles and blood vessels of the eyeball.

The sympathetic nervous system is sometimes called the visceral. It will be seen from the above that this term is not well suited in some respects, because the sympathetic supplies many structures which are not visceral. Another objection is that a great deal of important nerve-supply to the viscera is furnished by parts of the autonomic system other than sympathetic. That the sympathetic does, however, of itself constitute a more or less homogeneous entity is indicated by a curious fact. The substance adrenalin, which is the active constituent of extracts of the adrenal gland, has the property when introduced into the circulation of exciting all over the body just those actions which stimulation of the efferent fibres of the sympathetic causes, and no others. It is possible that when a nerve is stimulated some body at the nerve ending is set free, and this by combining with another chemical substance induces activity in the end organ (gland or muscle). It may be that when a sympathetic nerve is excited adrenalin is set free and combines with some substance which induces activity.

The rest of the autonomic system consists of two portions, a cranial and a sacral, so called from their proceeding from cranial and sacral nerve-roots respectively. The cranial portion is subdivided into a part belonging to the mid-brain and a part belonging to the hind-brain. The ciliary ganglion belonging to the eyeball is the ganglion of the former part, and its post-ganglionic fibres innervate the iris and the ciliary muscles. The hind-brain portion gives pre-ganglionic fibres to the facial (intermedius) glossopharyngeal and vagus nerves; its post-ganglionic distribution is to the blood vessels of the mucous membrane of the mouth and throat, to the musculature of the digestive tube from the oesophagus to the colon, to the heart, and to the musculature of the windpipe and lungs.

The sacral part of the autonomic system issues from the spinal cord with the three foremost sacral nerves. Its ganglia are scattered in the neighbourhood of the pelvic organs, which they innervate. The distribution of its post-ganglionic fibres is to the arteries of rectum, anus and external genitalia, to the musculature of colon, rectum, anus and the urinary bladder, and to that of the external genitalia.

The part played by the sympathetic and the rest of the autonomic system in the economy of the body is best considered by following broad divisions of organic functions.

Movements of the Digestive Tube.—It is those movements of alimentation not usually within range of our consciousness which the autonomic system regulates and controls. Nor is its control over them apparently essential or very complete. For instance, the pendular and peristaltic movements of the intestine still go forward when all nerves reaching the viscus have been severed. Extirpation of the abdominal sympathetic has not led to obvious disturbance of digestion or nutrition in the dog. It is noteworthy that the sympathetic inhibits contraction of the musculature of the stomach and intestine, while the other, the vagus, portion of the autonomic system excites it. The actions of these two components of the system are, therefore, mutually opposed on the viscera innervated by both.

Action on the Circulation.—The blood supply of most organs is under the control of vaso-constrictor nerves. All vaso-constrictor nerves are sympathetic. Organs to which vaso-constrictor nerves are supplied either poorly or not at all are the lungs, heart, liver, brain and probably the skeletal muscles. The blood vessels of certain parts of the body have, in addition to vaso-constrictor nerves, nerves which relax their muscular wall, vaso-dilatator nerves. The latter are never furnished by the sympathetic, they are in the mucous membranes and glands at the oral end of the body furnished by the cranial portion of the autonomic system. In regions at the aboral end of the body they are furnished by the sacral portion of the autonomic system. Elsewhere the vaso-dilatators when present are derived from the nerve-cells of the spinal ganglia (Bayliss).

The control of the calibre of the blood vessels by the autonomic system is of importance in several well-ascertained respects. By constricting the blood vessels of the viscera the system is able to favour an increase of blood supply to the brain. A noteworthy instance of such an action occurs when the erect attitude is assumed after a recumbent posture. Were it not for vaso-constriction in the abdominal organs the blood would then, under the action of gravity, sink into the more dependent parts of the body and the brain would be relatively emptied of its supply, and fainting and unconsciousness result. Again, it is essential to the normal functioning of the organs of warm-blooded animals that their temperature, except in the surface layer of the skin, should be kept constant. Part of the regulative mechanism for this lies in nervous control of the quantity of blood flowing through the surface sheet of the skin. That sheet is a cool zone through which a greater or smaller quantity of blood may, as required, be led and cooled. By the sympathetic vaso-constrictors the capacity of these vessels in the cool zone can be reduced, and thus the loss of heat from the body through that channel lessened. In cold weather the vaso-constrictors brace up these skin vessels and lessen the loss of heat from the body's surface. In hot weather the tonus of these nerves is relaxed and the skin vessels dilate; a greater proportion of the blood then circulates through the comparatively cool skin-zone.

The heart itself is but a specialized part of the blood-vascular tubing, and its musculature, like that of the arteries, receives motor nerves from the sympathetic. These nerves to the heart from the sympathetic are known as the accelerators, since they quicken and augment the beating of the cardiac muscle. The heart receives also nerves from the cranial part of the autonomic system, and the influence of these nerves is antagonistic to that of the sympathetic supply. The cranial autonomic nerves to the heart pass via the vagus nerves and lessen the beating of the heart both as to rate and force. These inhibitory nerves of the heart are analogous to the dilatator nerves to the blood vessels, which, as mentioned above, come not from the sympathetic, but from the cranial and sacral portions of the autonomic system.

Skin-glands.—In close connexion with the temperature regulating function of the sympathetic stands its influence on the sweat secreting glands of the skin. Secretory nerves to the sweat glands are furnished apparently exclusively by the sympathetic.

Pilomotor Nerves.—The skin in many places contains muscle of the unstriped kind. Contraction of this cutaneous muscular tissue causes knotting of the skin as in "goose-skin," and erection of the hairs as in the cat, or of the quills as in the hedgehog and porcupine. The efferent nerve-fibres to the unstriped muscles of the skin are always furnished by the sympathetic (pilomotor nerves, &c.). In this case the sympathetic contributes to emotional reactions and perhaps further to the regulation of temperature, as by ruffling the fur or feathers in animals exposed to the cold.

The Respiratory Tube.—The windpipe and the air passages of the lungs contain in their walls much unstriped muscular tissue, arranged so as to control the calibre of the lumen. The nerve-supply to this muscular tissue is furnished by the cranial autonomic system via the vagus nerves.

Eyeball.—An important office of the sympathetic is the controlling of the brightness of the visual image by controlling the size of the pupil. The sympathetic sends efferent fibres to the dilatator muscle of the pupil. In this case, as in others noted above, the cranial part of the autonomic system sends nerves of antagonistic effect to those of the sympathetic, first through the third cranial nerves from the efferent fibres to the constrictor muscle of the pupil. This same part of the cranial autonomic system supplies also motor fibres to the ciliary muscle, thus effecting the accommodation of the lens for focusing clearly objects within the range of what is termed near-vision.

Of the afferent fibres of the sympathetic little is known save that they are, relatively to the efferent, few in number, and that they, like the afferents of the cerebro-spinal system, are axones of nerve-cells seated in the spinal ganglia. (C. S. S.)

SYMPHONIA (Gr. *συμφωνία*), a much discussed word, applied at different times (1) to the bagpipe, (2) to the drum, (3) to the hurdy-gurdy, and finally (4) to a kind of clavichord. The sixth of the musical instruments enumerated in Dan. iii. 5, 10, 15, erroneously translated "dulcimer," in all probability refers to the bagpipe (*q.v.*). *Symphonia*, signifying drum, occurs in the writings of Isidor of Seville. "Tympanum est pellis vel corium ligno ex una parte extentum. Est enim pars media symphoniae in similitudinem cribri. Tympanum autem dictum quod medium est. Unde, et margaritum medium tympanum dicitur, et ipsum ut symphonia ad virgulam percutitur." The reference comparing the tympanum (kettledrum) to half a pearl is borrowed from Pliny (*Nat. hist. IX.* 35, 23). *Symphonia* or *Chifonie* was applied during the 13th and 14th centuries, in the Latin countries more especially, to the hurdy-gurdy. *Symphonia* is applied by Praetorius[1] to an instrument which he classed with the clavichord, spinet, regals and virginal, but without giving any clue to its distinctive characteristics. (K. S.)

SYMPHONIC POEM (*Symphonische Dichtung*, *Tondichtung*, *Poème symphonique*, &c.). This term covers the experiments in a new style of instrumental music which first showed a coherent method in the twelve *Symphonische Dichtungen* of Liszt. The term at present implies a large orchestral composition which, whatever its length and changes of tempo, is not broken up into separate movements, and which, moreover, illustrates a definite poetic train of thought that can be expressed in literature, whether it is actually so expressed or not. Thus the form of the symphonic poem is the form dictated by its written programme or unwritten poetic idea; and so it is not every piece of "programme music" that can be called a symphonic poem. Beethoven's sonata *Les Adieux*, and his *Pastoral Symphony*, are, for instance, works in which the poetic idea does not interfere with the normal development of sonata style required by the musical nature of Beethoven's material.

Great disturbances in musical art have always been accompanied by constant appeals to external literary ideas; and there is nothing peculiarly modern in the present tendency to attack and defend the rising style of large indivisible schemes of instrumental music by unprofitable metaphysical discussions as to the claims of "absolute music" against "music embodying poetic ideas." New art-forms are not born mature, and in their infancy their parent arts naturally invite other arts to stand godfather. If the rise of the sonata style was not accompanied by as much "programme music" as the new art of the present day (and as a matter of fact it was accompanied by a good deal), it at all events coincided with highly Wagnerian discussions

[1] See "Syntagm. mus." pt. ii., *De organographia*, pp. 72, 73, 178 (Wolfenbüttel, 1618).

of dramatic music on literary grounds. What is certain is, firstly, that no amount of theorizing can prevent a musician from developing his musical ideas; secondly, that musical ideas are just as likely to be inspired by literature and other arts as by any other kind of experience; and lastly, that, as musicians attain greater mastery in the handling of their ideas, their musical readiness soon outstrips their powers or inclination for literary analysis, at all events while they are working at the music. Hence the frequent ability of great composers to set inferior words to music which is not only great but evidently based upon those words. Hence the digust of great composers at even the cleverest unauthorized literary interpretations of their works. Hence, on the other hand, the absence of any general classical attitude of vigorous protest against the use of music to convey external ideas. Be this as it may, we believe the importance of the symphonic poem to lie not in its illustrative capacity, but in its evident tendency towards a new kind of instrumental art.

It is not mere convention and prejudice that has delayed the ripening of this art. Every classical art-form is made by the greatest artists to be a natural thing in every individual case, no matter how artificial the conditions of the form become in ordinary hands. In the highest classical art not even a thousand examples identical in form would really be examples of an art-form set up like a mould for the material to be shovelled into it. In each case, however much the artist may have been helped by custom, his material would have taken that shape by its own nature. A sufficient number of sufficiently similar cases of this kind may conveniently, though dangerously, be regarded as establishing an art-form; and most art-forms coincide to a striking degree with practical and local limitations, for in these a great artist can almost always find suggestions for the character of his material instead of mere hindrances to its development. Thus art-forms become the vehicle for perfectly natural works in the hands of great artists, even when in the abstract they are highly artificial and conventional. But there is probably no case of an important art-form (and still less of a whole style of art) remaining productive in so artificial a condition when the facts which made that condition natural are changed. The great works in such forms remain, and are thoroughly natural, for they express their environment so perfectly as to recall it. It makes singularly little difference to the value of a great work of art, in the long run, whether its vividness is in the light it throws on a remote and forgotten past, or on a living and actual present. When Alcinous welcomes Odysseus, on hearing that he is an honourable pirate and not one of those disreputable merchants, our pleasure at the realistic glimpse of Homeric social distinctions differs from the pleasure of the Homeric audience only in so far as our point of view is more romantic. But new art must, if it is to live, be produced, like the classics, on conditions which the artist himself understands; and it is improbable that these conditions (if they admit of healthy art at all) will be of a less common-sense character than those of older art.

In the absence of musical criteria for a future art, perhaps the analogy of drama may be useful here. The chorus of Greek tragedy can by no stretch of imagination be said to behave like a corresponding group of persons in real life. Yet the Greek chorus becomes natural enough when we realize the necessary material circumstances of Greek drama; indeed in the best examples it becomes the only natural (or even, in a certain religious aspect, realistic) treatment of a natural set of materials. In the same way we are taught that Shakespeare's dramatic technique becomes perfectly natural when we realize his equally natural type of stage, which was so constructed and situated in regard to the audience that scenery would obstruct the view just as it would in a circus. But with the modern conception of a stage as a kind of magnified peep-show, with the audience looking into a painted box, realistic scenery is inevitable; and with realistic scenery comes speech so realistic that the use of verse and other classical resources is attended with dangers hitherto unknown. At the same time the condition of the modern stage obviously approximates far more closely to such an idea of the art of imitating human life by human speech and action, as would most naturally occur to a common-sense mind at any period. And it is probable that the final condition of an art will always tend to approximate to such an idea. In the same way it cannot be doubted that the sonata form, with its subtle balance between independence of form and interdependence of contrast, is far too artificial to be such a final form of instrumental music as would commend itself in the abstract to ordinary common sense. And we may look forward to a time, perhaps by the middle of the century, when the new and single continuous forms now adumbrated by the symphonic poems shall be the greatest forms of instrumental music, and shall need no literary crutches to make them intelligible. The pioneers of these forms at the present day frequently and sometimes justifiably claim that their music is intelligible apart from its "programme," but this is far from being so constantly the case that the symphonic poem can as yet be regarded as a mature kind of art. But when the mature art it foreshadows shall appear, then critics will need to face the fact that its genuine achievements will outwardly resemble the immature efforts which led to them, while the spiritual resemblance to classical music will lie too deep for the recognition of any but those who have the courage to make the new art their own. The symphonies of Mozart are in texture and phraseology far more like those of Philipp Emanuel Bach than they are like the great works of John Sebastian Bach; and if we try the experiment of reading one of John Sebastian's motets after a long course of Palestrina, we may realize that a lover of the Palestrina style living during the monodic revolution would really have had no means of telling the difference between Bach's art and the squalid sensational impressionism of Gesualdo, the prince of Venosa. Yet the impassable gulf is in all cases that between the great art and the crude efforts that foreshadow it, while the universal spirit of mature art remains the same whether the age or style be called "classical," "romantic," or "secessionist."

See also PROGRAMME MUSIC and SONATA FORMS (*ad fin.*).

(D. F. T.)

SYMPHONY in music. 1. The term *συμφωνία* was used by the Greeks, firstly, to denote the general conception of concord, both between successive sounds and in the unison of simultaneous sounds; secondly, in the special sense of concordant pairs of successive sounds (*i.e.* the "perfect intervals" of modern music; the 4th, 5th and octave); and thirdly as dealing with *τὸ ἀντίφωνον*, the concord of the octave, thus meaning the art of singing in octaves, or *magadizing*, as opposed to *ὁμοφωνία*, or singing and playing in unison. In Roman times the word appears in the general sense which still survives in poetry, viz. as harmonious concourse of voices and instruments. It also appears to mean a concert. In St Luke xv. 25, it is distinguished from *χόροι*, and the passage is appropriately translated in the English Bible as "music and dancing." Polybius and others seem to use it as the name of a musical instrument.

2. In the 17th century the term is used, like "concerto," for certain vocal compositions accompanied by instruments, *e.g.* the *Kleine geistliche Concerte* and *Symphoniae sacrae* of Schütz. Most of Schütz's works of this class are for from one to three solo voices in various combinations with instruments. The *Geistliche Concerte* are generally accompanied by figured bass and are to German texts; and the voices may in many cases be choral. The *Symphoniae sacrae* are to Latin texts and are written for various combinations of instruments, while the voice parts are evidently for solo singers. The word symphony is sometimes used for the instrumental ritornello of songs and vocal movements in aria form. In this sense it already appears in No. 28 of the second book of Schütz's *Geistliche Concerte.*

3. The principal modern meaning of the word is a sonata for orchestra (see SONATA FORMS). The orchestral symphony originated in the operatic overture (*q.v.*), which in the middle of the 18th century began to assimilate the essentials of the sonata style. At first such sonata-style overtures consisted of

three movements, viz. a moderately quick binary movement, a short slow movement, and a lively finale. Thus Mozart, at the age of twelve, used his 7th symphony as the overture to *La Finta semplice*, and Haydn's maturest symphonies are still called overtures in some early editions. *La Finta giardiniera*, written by Mozart in his eighteenth year, marks the differentiation of the opera overture from the independent symphony, since it contains the usual first movement and slow movement, but the curtain rises with what sounds like the beginning of the finale.

The sonata style was not at first invariably associated with what we now call sonata form, nor indeed was that form at first the most favourable to the dramatic expression desirable for operatic music. Hence the overtures of Gluck are generally in forms based on the contrast of loosely knit passages of various textures; forms which he probably learned from San Martini, and which may be found in the concertos of Vivaldi, so many of which were freely transcribed by Sebastian Bach. These methods are no less evident in the symphonies of Philipp Emmanuel Bach, which thus occupy an analogous place, away from the normal line of the sonata style. The differentiation between symphony and overture was of immense importance in raising the dignity of the symphony; but the style was more essential than the form; and in Mozart's and Haydn's mature works we find the sonata form as firmly established in the overture as in the symphony, while nevertheless the styles and scope of the two forms are quite distinct. Mozart's most elaborate overture, that of *Die Zauberflöte*, could not possibly be the first movement of one of his later symphonies; nor could the finale of his "Jupiter" symphony (which has often been compared with that overture because of its use of *fugato*) conceivably be used as the prelude to an opera.

See also MUSIC; SONATA FORMS; INSTRUMENTATION; OVERTURE; SCHERZO; VARIATIONS. (D. F. T.)

SYMPHOSIUS, or SYMPOSIUS, the name given to the author of a collection of 100 riddles of uncertain date, but probably composed in the 4th or 5th century A.D. They have been attributed to Lactantius, and identified with his *Symposium*, but this view is not generally accepted. The style and versification of the riddles, each of which consists of three hexameter lines, are good. They were written to form part of the entertainment at the Saturnalia.

Text in E. Bährens, *Poetae latini minores*, vol. iv.; there is a good French metrical version by E. F. Corpet (1868); monograph by W. T. Paul (Berlin, 1854); see also Teuffel, *Hist. of Roman Literature*, 449 (Eng. trans., 1900).

SYMPOSIUM (Gr. *συμπόσιον*, a drinking party, from *συμπίνειν*, to drink together, *σύν*, with, and *πίνειν*, to drink, root *πο*, cf. Lat. *potare*, to drink, *poculum*, cup), the convivial drinking which took place after a great banquet, accompanied by intellectual or witty conversation, and by music or dancing performed by slaves or attendants. The term has been applied in modern usage, due to Plato's *Symposium*, to a collection of opinions of different writers on a given subject.

SYNAGOGUE (*συναγωγή*), literally "assemblage," is the term employed to denote either a congregation of Jews, *i.e.* a local circle accustomed to meet together for worship and religious instruction, or the building in which the congregation met. In the first sense the word is a translation of כנסת, *keneseth* (assemblage), in the second of בית הכנסת, *bēth hakkeneseth* (house of assemblage). Further the term is often used to denote the system of Judaism, as when the "Synagogue" is contrasted to the "Church." The germ of the synagogue, that is, of religious assemblages dissociated from the ancient ritual of the altar, may be found in the circle of the prophets and their disciples (see especially Isa. viii. 16 seq.); but the synagogue as an institution characteristic of Judaism arose after the work of Ezra, and is closely connected with the development of Judaism, to which his reformation gave definite shape. From the time of Ezra downwards it was the business of every Jew to know the law; the school (*bēth hammidrāsh*) trained scholars, but the synagogue, where the law was read every Sabbath (Acts xv. 21), was the means of popular instruction. Such synagogues existed in all parts of Judaea in the time of Ps. lxxiv. 8 (probably a psalm of the Persian period); in Acts xv. 21 it appears that they had existed for many generations "in every city." This held good not only for Palestine, but for the Dispersion; in post-Talmudic times the rule was that a synagogue must be built wherever there were ten Jews. In the Dispersion the synagogue filled a greater place in the communal life, for on Palestinian soil the Temple enjoyed a predominant position. In this sense the synagogue is a child of the Dispersion, but this does not imply that it was a product of the Hellenic diaspora. For the Aramaic papyri discovered at Assuan show that in the 5th century B.C. the Egyptian Jews had their place of worship in Syene long before Greek influences had begun to make themselves felt. The fact that the Books of the Maccabees never refer to synagogues is not evidence that synagogues were unknown in Judaea in the Maccabean period. These books refer mostly to a time of war, when assemblages in the cities were impossible; their interest, moreover, is concentrated in the Temple and the restoration of its services. During the second Temple there is no doubt but that public worship was organized in the provinces as well as in the Jewish settlements outside the Holy Land. And though the name "synagogue" varies with *προσευχή* ("place of prayer"), it appears that everywhere the assemblage was primarily one for instruction in the law; the synagogue, as Philo puts it, was a *διδασκαλεῖον*. Prayer, in the more restricted sense, invariably accompanied the instruction, and several parts of the extant liturgy go back to the 3rd century B.C. A formed institution of this sort required some organization: he general order of the service was directed by one or more "rulers of the synagogue" (*ἀρχισυνάγωγοι*, Luke xiii. 14; Acts xiii. 15), who called on fit persons to read, pray and preach; alms were collected by two or more "collectors" (*gabbāē ṣedāqā*); and a "minister" (*ḥazzān*, *ὑπηρέτης*, Luke iv. 20) had charge of the sacred books (preserved in an "ark") and of other ministerial functions, including the teaching of children to read. The discipline of the congregation was enforced by excommunication (*ḥērem*) or temporary exclusion (*niddūi*), and also by the minor punishment of scourging (Matt. x. 17), inflicted by the *ḥazzān*. The disciplinary power was in the hands of a senate of elders (*πρεσβύτεροι*, *γερουσία*), the chief members of which were *ἄρχοντες*. The principal service of the synagogue was held on Sabbath morning, and included, according to the Mishnah, the recitation of the *shema'* (Deut. vi. 4-9, xi. 13-21; Num. xv. 37-41), prayer, lessons from the law and prophets with Aramaic translation, a sermon (*derāshah*) based on the lesson (Acts xiii. 15), and finally a blessing pronounced by the priest or invoked by a layman. On Sabbath afternoon and on Monday and Thursday there was a service without a lesson from the prophets; there were also services for all feast-days. Synagogues were built by preference beside water, in order to avoid proximity to the idol temples, rather than, as some think, for the convenience of the ceremonial ablutions (cf. Acts xvi. 13). Remains of very ancient buildings of this class exist in several parts of Galilee; they generally lie north and south, and seem to have had three doors to the south, and sometimes to have been divided by columns into a nave and two aisles.

Modern synagogues are mostly built of oblong shape, with a gallery for women. Since the middle ages, Renaissance and Moorish types of decoration have been generally favoured, but there is nowadays a great variety of types. The ancient synagogue of Alexandria (destroyed by Trajan) was a basilica. A number of recent synagogues have been built in octagonal form. The main interior features of the synagogue are the "ark" (a cupboard containing the scrolls of the law, &c.) and the *almemar* (or reading-desk, from the Arabic *al-minbar*, pulpit). This is sometimes in the centre, sometimes at the eastern end of the building. The Talmud prescribed an elevated site for the synagogue, but this rule has been impossible of fulfilment in modern times. The synagogues are theoretically "orientated" —*i.e.* the ark (which worshippers face during the principal prayer) is on the eastern side. But this rule, too, is often ignored under the stress of architectural difficulties.

Jewish tradition has a great deal to say about a body called "the great synagogue," which is supposed to have been the supreme religious authority from the cessation of prophecy to the time of the high priest Simeon the Just, and is even said to have fixed the Old Testament canon (cf. v. 3 seq.). But Kuenen in his essay "Over de Mannen der Groote Synagoge" (*Verslagen* of the Amsterdam Academy, 1876) has powerfully argued that these traditions are fiction, and that the name *keneseth haggādōla* originally denoted, not a standing authority, but the great convocation of Neh. viii.–x. Some more recent scholars are, however, more willing to attach credence to the older tradition.

Compare, in general, Schürer, *Geschichte des jüdischen Volkes*, § 27, where the older literature is catalogued. For some unconventional views the reader may refer to M. Friedländer, *Synagoge und Kirche in ihren Anfängen* (Berlin, 1908). For the usages of the synagogue in more recent times, see Buxtorf, *Synagoga judaica* (Basel, 1641). On the history of synagogue services the works of Zunz are the chief authorities; there is also a good article on Liturgy in the *Jewish Encyclopedia*. Useful summaries in English are to be found in Dembitz, *Jewish Services in Synagogue and Home* (Philadelphia, 1898); and Oesterley and Box, *The Religion and Worship of the Synagogue* (London, 1907). The article "Synagogue" in the *Jewish Encyclopedia* is illustrated with numerous pictures of buildings and plans.

SYNAGOGUE, UNITED, an organization of London Jews, founded, with the sanction of an act of parliament, in 1870. It is confined, in its direct work, to the metropolis, but it exercises, indirectly, considerable influence over the Jews of the British Empire. It is governed by an elected council representing the constituent congregations. In religious and ritual matters it is under the jurisdiction of the chief rabbi, who is, to a certain extent, recognized throughout the empire. The president of the United Synagogue in 1910 was Lord Rothschild. Besides providing the worship of some twenty congregations, the United Synagogue directs and supports educational and charitable work. The title "chief rabbi" is not found in the pre-expulsion records, though, before the Jews were banished in 1290, there was an official named "presbyter omnium Judaeorum Angliae." The functions of this official cannot be proved to have been ecclesiastical. The title "chief rabbi" has become well known through the eminence of recent occupants of the position such as Solomon Hirschell (1762–1842). He was succeeded by Dr Nathan Marcus Adler (1803–1890), who was followed by his son, Hermann Adler, who raised the position to one of much dignity and importance. Dr Hermann Adler was born in Hanover in 1839, graduated at Leipzig, and received honorary degrees from Scotch and English universities, including Oxford. In 1909 he received the order of M.V.O. Dr Adler was elected chief rabbi in 1891. Besides several essays in the *Nineteenth Century*, Dr Adler has written extensively on topics of Anglo-Jewish History and published two volumes of sermons. (I. A.)

SYNANTHY (Gr. σύν, with, and ἄνθος, a flower), a botanical term for the adhesion of two or more flowers.

SYNAXARIUM (Gr. συναξάριον, from συνάγειν, to bring together), the name given in the Greek Church to a compilation corresponding very closely to the martyrology (*q.v.*) of the Roman Church. There are two kinds of synaxaria—simple synaxaria, which are merely lists of the saints arranged in the order of their anniversaries, *e.g.* the calendar of Morcelli; and historical synaxaria, which give biographical notices besides, *e.g.* the menology of Basil and the synaxarium of Sirmond. The notices given in the historical synaxaria are summaries of those in the great menologies, or collections of lives of saints, for the twelve months of the year. The oldest historical synaxaria apparently go back to the tenth century. The heterodox Eastern churches also have their synaxaria.

The publication of the Arabic text of the synaxarium of the Church of Alexandria was started simultaneously by J. Forget in the *Corp. script. orient.* and by R. Basset in the *Patrologia orient.*, and that of the Ethiopian synaxarium was begun by I. Guidi in the *Patrologia orient.* The Armenian synaxarium, called the synaxarium of Ter Israël was published at Constantinople in 1834.

See S. A. Morcelli, *Kalendarium ecclesiae Constantinopolitanae* (Rome, 1788); H. Delehaye, "Le Synaxaire de Sirmond," in *Analecta bollandiana*, xiv. 396–434, where the terminology is explained; idem, *Synaxarium ecclesiae Constantinopolitanae e codice Sirmondiano* (Brussels, 1902), forming the volume *Propylaeum ad acta sanctorum novembris*. (H. De.)

SYNCELLUS, a hybrid word (Gr. σύν, Lat. *cella*),[1] meaning literally "one who shares his cell with another." In ecclesiastical usage it refers to the very early custom of a priest or deacon living continually with a bishop, *propter testimonium ecclesiasticum*; thus Leo III. speaks of Augustine as having been the *syncellus* of Gregory the Great. The term came into use in the Eastern Church, where the *syncelli* were the chaplains of metropolitans and patriarchs. At Constantinople they formed a corporation, and the *protosyncellus* took precedence of metropolitans and ranked next to the patriarch, to whose office he generally succeeded.

SYNCOPE (Gr. συγκοπή, a cutting up or short, from κόπτειν, to cut), a term used in grammar for the elision of a letter or syllable in the middle of a word (*e.g.* "ne'er" for "never"); and in medicine for the condition of fainting or shock (*q.v.*); and so occasionally in a general sense for a suspension or cessation of function. "Syncopate" and "syncopation" are analogous derivatives; and in music a syncopation is the rhythmic method of tying (⌒) two beats of the same note into one tone in such a way as to displace the accent.

SYNCRETISM (Gr. συγκρητισμός, from σύν and κεράννυμι, mingle or blend, or, according to Plutarch, from σύν and κρητίζειν, to combine against a common enemy after the manner of the cities of Crete), the act or system of blending, combining or reconciling inharmonious elements. The term is used technically in politics, as by Plutarch, of those who agree to forget dissensions and to unite in the face of common danger, as the Cretans were said to have done; in philosophy, of the efforts of Cardinal Bessarion and others in the 16th century to reconcile the philosophies of Plato and Aristotle; and in theology, of a plan to harmonize the hostile factions of the Church in the 17th century, advocated by Georg Calixtus, a Lutheran professor of theology at Helmstadt. Its most frequent use, however, is in connexion with the religious development of antiquity, when it denotes the tendency, especially prominent from the 2nd to the 4th centuries of the Christian era, to simplify and unify the various pagan religions. During this period, as a result of the intimate knowledge of the world's religions made possible by the gathering of every known cult of importance into the religious system of the Roman Empire, belief in the identity of many deities which resembled each other, and indeed in the essential identity of all, received a special impulse. Not only were various forms of the same deity, such as, for example, Jupiter Capitolinus and Jupiter Latiaris, recognized as being really the same under different aspects, but even the gods of different nations were seen to be manifestations of a single great being. Roman Jupiter, Greek Zeus, Persian Mithras and Phrygian Attis were one. The Great Mother, Isis, Ceres, Demeter, Ops, Rhea, Tellus, were the same great mother deity under different masks (see GREAT MOTHER OF THE GODS). Venus and Cupid, Aphrodite and Adonis, the Great Mother and Attis, Astarte and Baal, Demeter and Dionysus, Isis and Serapis, were essentially the same pair. Syncretism even went so far as to blend the deities of paganism and Christianity. Christ was compared with Attis and Mithras, Isis with the Virgin Mary, &c. Isis, perhaps more than any other deity, came to be regarded as the great maternal goddess of the universe whose essence was worshipped under many different names. This fact, with the spirit of syncretism in general, is well illustrated by Apuleius (*Metamorph.* xi. 2 and 5). Lucius invokes Isis: "Queen of Heaven, whether thou art the genial Ceres, the prime parent of fruits, who, joyous at the discovery of thy daughter, didst banish the savage nutriment of the ancient acorn, and, pointing out a better food, dost now till the Eleusinian soil; or whether thou art celestial Venus, who, in the first origin of things, didst

[1] Apollinaris Sidonius uses the pure Latin term *concellus*.

associate the different sexes, through the creation of mutual love, and having propagated an eternal offspring in the human race, art now worshipped in the sea-girt shrine of Paphos; or whether thou art the sister of Phoebus, who, by relieving the pangs of women in travail by soothing remedies, hast brought into the world multitudes so innumerable, and art now venerated in the far-famed shrines of Ephesus; or whether thou art Proserpine, terrific with midnight howlings . . . by whatever name, by whatever ceremonies, and under whatever form it is lawful to invoke thee; do thou graciously, &c." The goddess replies: "Behold me . . . I, who am Nature, the parent of all things, the mistress of all the elements, the primordial offspring of time, the supreme among divinities, the queen of departed spirits, the first of the celestials, and the uniform manifestation of the gods and goddesses; who govern by my nod the luminous heights of heaven, the salubrious breezes of the ocean, and the anguished silent realms of the shades below; whose one sole divinity the whole orb of the earth venerates under a manifold form, with different rites, and under a variety of appellations. Hence the Phrygians, that primeval race, call me Pessinuntica, the Mother of the Gods; the Aborigines of Attica, Cecropian Minerva; the Cyprians, in their sea-girt isle, Paphian Venus; the arrow-bearing Cretans, Diana Dictynna; the three-tongued Sicilians, Stygian Proserpine; and the Eleusinians, the ancient goddess Ceres. Some call me Juno, others Bellona, others Hecate, others Rhamnusia. But those who are illumined by the earliest rays of that divinity, the Sun, when he rises, the Aethopians, the Arii, and the Egyptians, so skilled in ancient learning, worshipping me with ceremonies quite appropriate, call me by my true name, Queen Isis. Behold, then, &c." (Trans. Bohn's Lib.).

Naturally, the influence of Greek philosophy was very pronounced in the growth of syncretism. Plutarch and Maximus of Tyre affirmed that the gods of the different nations were only different aspects of the same deity, a supreme intelligence and providence which ruled the world. The Neoplatonists, however, were the first school to formulate the underlying philosophy of syncretism: "There is only one real God, the divine, and the subordinate deities are nothing else than abstractions personified, or celestial bodies with spirits; the traditional gods are only demons, that is, being intermediate between God and man . . . All, like every other created being, are emanations from the absolute God" (Jean Réville, *La Religion à Rome sous les Sévères*). Care must be taken, however, not to place too much emphasis upon syncretism as a conscious system. The movement which it represented was not new in the 2nd century A.D. The identification of Latin with Etruscan gods in the earliest days of Rome, and then of Greek with Italian, and finally of Oriental with the Graeco-Roman, were all alike syncretistic movements, though not all conscious and reasoned. The ideal of the common people, who were unreflecting, as well as of philosophers who reflected, was "to grasp the religious verity, one and constant, under the multiplex forms with which legend and tradition had enveloped it" (Réville). The advent of Greek philosophy only hastened the movement by conscious and systematic effort.

Syncretic, being a movement toward monotheism, was the converse of the tendency, so prominent in the early history of Rome, to increase the number of deities by worshipping the same god under special aspects according to special activities. In the hands of the Neoplatonists it was instrumental in retarding somewhat the fall of paganism for the time, but in the end contributed to the success of Christianity by familiarizing men with the belief in one supreme deity. The triumph of Christianity itself represented a result of syncretism, the Church being a blending of the beliefs and practices of both the new and old religions.

See Jean Réville, *op. cit.*, especially pages 104–127, 159–174, 284–295. For other examples of syncretism, cf. that of Buddhism Zoroastrianism in the state religion of the Indo-Scythian kingdom of Kanishka (see PERSIA: *Ancient History*, vii.; *The Parthian Empire*, § 2); see articles on almost all the religions of the East, *e.g.* MITHRAS; ZOROASTER. (G. SN.)

SYNDERESIS, a term in scholastic philosophy applied to the inborn moral consciousness which distinguishes between good and evil. The word is really *synteresis* (Gr. *συντήρησις*, from *συντηρεῖν*, to look after, take care of), but synderesis is the commoner form. Diogenes Laërtius in his account of the Stoics (vii.85, *τὴν δὲ πρώτην ὁρμήν φασι τὸ ζῷον ἴσχειν ἐπὶ τὸ τηρεῖν ἑαυτό*) uses the phrase *τηρεῖν ἑαυτό* to describe the instinct for self-preservation, the inward harmony of Chrysippus, the recognition of which is *συνείδησις*. The term *synderesis*, however, is not found till Jerome, who in dealing with Ezek. i. 4–15, says the fourth of the "living creatures" of the vision is what the Greeks call *συντήρησις*, *i.e. scintilla conscientiae* the "spark of conscience." Here apparently synderesis and conscience (*συνείδησις*) are equivalent. By the schoolmen, however, the terms were differentiated, conscience being the practical envisaging of good and evil actions; synderesis being, so to speak, the tendency toward good in thought and action. The exact relation between the two was, however, a matter of controversy, Aquinas and Duns Scotus holding that both are practical reason, while Bonaventura narrows synderesis to the volitional tendency to good actions.

SYNDIC (Late Lat. *syndicus*, Gr. *σύνδικος*, one who helps in a court of justice, an advocate, representative, *σύν*, with, and *δίκη*, justice), a term applied in certain countries to an officer of government with varying powers, and secondly to a representative or delegate of a university, institution or other corporation, entrusted with special functions or powers. The meaning which underlies both applications is that of representative or delegate. Du Cange (*Gloss. s.v. Syndicus*), after defining the word as *defensor*, *patronus*, *advocatus*, proceeds "*Syndici* maxime appellantur Actores universitatum, collegiorum, societatum et aliorum corporum, per quos, tanquam in republica quod communiter agi fierive oportet, agitur et fit," and gives several examples from the 13th century of the use of the term. The most familiar use of "syndic" in the first sense is that of the Italian *sindico*, who is the head of the administration of a commune, answering to a "mayor"; he is a government official but is elected by the communal council from their own members by secret ballot.

Nearly all the companies, gilds, and the university of Paris had representative bodies the members of which were termed *syndici*. Similarly in England, the senate of the university of Cambridge, which is the legislative body, delegates certain functions to special committees of its members, appointed from time to time by Grace, *i.e.* a proposal offered to the senate and confirmed by it; these committees are termed "syndicates" and are permanent or occasional, and the members are styled "the syndics" of the particular committee or of the institution which they administer; thus there are the syndics of the Fitzwilliam Museum, of the University Press, of the Observatory, of local examinations and lectures, of the Antiquarian Committee, &c.

SYNDICATE, a term originally meaning a body of syndics. In this sense it is still sometimes used, as at the university of Cambridge, for the body of members or committee responsible for the management of the University Press. In commerce, a syndicate is a body of persons who combine to carry through some financial transaction, or who undertake a common adventure. Syndicates are very often formed to acquire or take over some undertaking, hold it for a short time, and then resell it to a company. The profits are then distributed and the syndicate dissolves. Sometimes syndicates are formed under agreements which constitute them mere partnerships, the members being therefore individually responsible, but they are now more generally incorporated under the Companies Acts.

The more usual cases in which syndicates are commonly formed will be found in F. B. Palmer's *Company Precedents*, 10th ed., vol. i. pp. 129 seq.

SYNECHISM (from Gr. *συνεχής*, continuous, from *σύν*, *ἔχειν*, to hold together), a philosophical term proposed by C. S. Peirce (*Monist*, ii. 534) to express the general theory that the essential feature in philosophic speculation is continuity. It is specially directed to the question of hypothesis, and holds that a hypothesis is justifiable only on the ground that it provides an explanation.

All understanding of facts consists in generalizing concerning them. The fact that some things are ultimate may be recognized by the synechist without abandoning his standpoint, since synechism is a normative or regulative principle, not a theory of existence. The adjective "synechological" is used in the same general sense; "synechology" is a theory of continuity or universal causation; "synechia" is a term in ophthalmology for a morbid union of parts.

SYNEDRIUM (*συνέδριον*), a Greek word which means "assembly" and is especially used of judicial or representative assemblies, is the name by which (or by its Hebrew transcription, סנהדרין, *sanhedrīn, sanhedrīm*) that Jewish body is known which in its origin was the municipal council of Jerusalem, but acquired extended functions and no small authority and influence over the Jews at large (see xiii. 424 seq.). In the Mishnah it is called "the sanhedrin," "the great sanhedrin," "the sanhedrin of seventy-one [members]" and "the great court of justice" (*bēth dīn haggādōl*). The oldest testimony to the existence and constitution of the synedrium of Jerusalem is probably to be found in 2 Chron. xix. 8; for the priests, Levites and hereditary heads of houses there spoken of as sitting at Jerusalem as a court of appeal from the local judicatories does not correspond with anything mentioned in the old history, and it is the practice of the chronicler to refer the institutions of his own time to an origin in ancient Israel. And just such an aristocratic council is what seems to be meant by the gerousia or senate of "elders" repeatedly mentioned in the history of the Jews, both under the Greeks from the time of Antiochus the Great (Jos. *Ant.* xii. 3, 3) and under the Hasmonean high priests and princes. The high priest as the head of the state was doubtless also the head of the senate, which, according to Eastern usage, exercised both judicial and administrative or political functions (cf. 1 Macc. xii. 6, xiv. 20). The exact measure of its authority must have varied from time to time at first with the measure of autonomy left to the nation by its foreign lords and afterwards with the more or less autocratic power claimed by the native sovereigns.

The original aristocratic constitution of the senate began to be modified under the later Hasmoneans by the inevitable introduction of representatives of the rising party of the Pharisees, and this new element gained strength under Herod the Great, the bitter enemy of the priestly aristocracy. Finally under the Roman procurators the synedrium was left under the presidency of the chief priest as the highest native tribunal, though without the power of life and death (John xviii. 31). The aristocratic and Sadducean element now again preponderated, as appears from Josephus and from the New Testament, in which "chief priests" and "rulers" are synonymous expressions. But with these there sat also "scribes" or trained legal doctors of the Pharisees and other notables, who are simply called "elders" (Mark xv. 1). The Jewish tradition which regards the synedrium as entirely composed of rabbins sitting under the presidency and vice-presidency of a pair of chief doctors, the *nāsī* and *āb bēth dīn*, is inconsistent with the evidence of Josephus and the New Testament. It is generally held that it was after the fall of the state that a merely rabbinical *bēth dīn* sat at Jabneh and afterwards at Tiberias, and gave legal responses to those who chose to admit a judicature not recognized by the civil power. Dr A. Büchler has sought to reconcile the various accounts by the theory that there were two great tribunals in Jerusalem, one wielding religious, the other civil authority (*Das Synedrion in Jerusalem*, Vienna, 1902).

The council chamber (*βουλή*) where the synedrium usually sat was between the Xystus and the Temple, probably on the Temple-hill, the Mishnah states that the meetings were held within the inner court. The meeting in the palace of the high priest which condemned Jesus was exceptional. The proceedings also on this occasion were highly irregular, if measured by the rules of procedure which, according to Jewish tradition, were laid down to secure order and a fair trial for the accused.

Of the older literature of the subject it is enough to cite Selden, *De synedriis*. The most important critical discussion is that of Kuenen in the *Verslagen*, &c., of the Amsterdam Academy (1866), p. 131 seq. A good summary is given by Schürer, *Geschichte des jüdischen Volkes*, 4th ed., § 23. Cf. also G. A. Smith, *Jerusalem* (1907), vol. i. ch. 9.

SYNESIUS (*c.* 373–*c.* 414), bishop of Ptolemais in the Libyan Pentapolis after 410, was born of wealthy parents, who claimed descent from Spartan kings, at Cyrene between 370 and 375. While still a youth (393) he went with his brother Euoptius to Alexandria, where he became an enthusiastic Neoplatonist and disciple of Hypatia (*q.v.*). On returning to his native place about the year 397 he was chosen to head an embassy from the cities of the Pentapolis to the imperial court to ask for remission of taxation and other relief. His address to Arcadius (*De regno*) is full of advice as to the studies of a wise ruler in such perilous times. His three years' stay in Constantinople was wearisome and otherwise disagreeable; the leisure it forced upon him he devoted in part to literary composition. The *Aegyptus sive de providentia* is an allegory in which the good Osiris and the evil Typhon, who represent Aurelian and the Goth Gainas (ministers under Arcadius), strive for mastery; and the question of the divine permission of evil is handled. After the successful Aurelian had granted the petition of the embassy, Synesius returned to Cyrene in 400, and spent the next ten years partly in that city, when unavoidable business called him there, but chiefly on an estate in the interior of the province, where in his own words "books and the chase" made up his life. His marriage took place at Alexandria in 403; in the previous year he had visited Athens. In 409 or 410 Synesius, whose Christianity had until then been by no means very pronounced, was popularly chosen to be bishop of Ptolemais, and, after long hesitation on personal and doctrinal grounds, he ultimately accepted the office thus thrust upon him, being consecrated by Theophilus at Alexandria. One personal difficulty at least was obviated by his being allowed to retain his wife, to whom he was much attached; but as regarded orthodoxy he expressly stipulated for personal freedom to dissent on the questions of the soul's creation, a literal resurrection, and the final destruction of the world, while at the same time he agreed to make some concession to popular views in his public teaching (*τὰ μὲν οἴκοι φιλοσοφῶν, τὰ δ' ἔξω φιλομυθῶν*). His tenure of the bishopric was troubled not only by domestic bereavements but also by barbaric invasions of the country (in repelling which he proved himself a capable military organizer) and by conflicts with the prefect Andronicus, whom he excommunicated for interfering with the Church's right of asylum. The date of his death is unknown; it is usually given as *c.* 414. His many-sided activity, as shown especially in his letters, and his loosely mediating position between Neoplatonism and Christianity, make him a subject of fascinating interest. His scientific interests are attested by his letter to Hypatia in which occurs the earliest known reference to areometry, and by a work on alchemy in the form of a commentary on pseudo-Democritus. He was a man of the highest personal character.

His extant works are—(1) a speech before Arcadius, *De regno*; (2) *Dio, sive de suo ipsius instituto*, in which he signifies his purpose to devote himself to true philosophy; (3) *Encomium calvitii* (he was himself bald), a literary *jeu d'esprit*, suggested by Dio Chrysostom's *Praise of Hair*; (4) *De providentia*, in two books; (5) *De insomniis*; (6) 157 *Epistolae*; (7) 12 *Hymni*, of a contemplative, Neoplatonic character; and several homilies and occasional speeches. The *editio princeps* is that of Turnebus (Paris, 1553); it was followed by that of Morell, with Latin translation by Petavius (1612; greatly enlarged and improved, 1633; reprinted, inaccurately, by Migne, 1859). The *Epistolae*, which for the modern reader greatly exceed his other works in interest, have been edited by Demetriades (Vienna, 1792) and by Glukus (Venice, 1812), the *Calvitii encomium* by Krabinger (Stuttgart, 1834), the *De providentia* by Krabinger (Sulzbach, 1835), the *De regno* by Krabinger (Munich, 1825), and the *Hymns* by Flach (Tübingen, 1875).

See Clausen, *De Synesio philosopho* (Copenhagen, 1831); R. Volkmann, *Synesius von Cyrene* (Berlin, 1869); A. Gardner's monograph in "The Fathers for English Readers" (London, 1886); and a life by W. S. Crawford (London, 1901).

SYNOD (Gr. *σύνοδος*), a term denoting an assembly of ecclesiastical officials legally convoked to discuss and decide points of faith, discipline and morals. It is practically synonymous with the word council (*q.v.*); *concilium* is used in the same technical sense by Tertullian *c.* 200, and *σύνοδος* a century or so later in the Apostolic canons. In time, however, the word council came to be restricted to oecumenical gatherings, while synod was applied to meetings of the eastern or western branches of the Church (the first council of Constantinople was originally a mere council or synod of the East), or to councils of the Reformed churches, *e.g.* the Synod of Dort. Provincial synods were held in the 2nd century, and were not completely organized before the advent of oecumenical councils. The two terms are still used side by side; thus there are patriarchal, national and primatial councils, as well as provincial councils (under the metropolitan of a province) and diocesan synods, consisting of the clergy of a diocese and presided over by the bishop (or the vicar-general). The supreme governing body in the Russian branch of the Orthodox Eastern Church (*q.v.*) is known as the Holy Synod. In the Presbyterian churches (see PRESBYTERIANISM) a synod is an assembly containing representatives of several presbyteries and intermediate between these and the General Assembly; similarly in the Wesleyan and other Methodist churches the synod is the meeting of the district which links the circuits with the conference. The term is not in use in self-governing churches like the Congregationalists and Baptists, though these from time to time hold councils or assemblies (national and international), for conference and fellowship without any legislative power.

SYNODIC PERIOD, in astronomy, the apparent period of a planet or satellite when its revolution is referred to the line passing through the earth or the sun. In the case of the planets it is the period between successive conjunctions of the same kind, inferior or superior, with the sun. In the case of the satellites it is the period relative to the radius vector from the sun.

SYNTHESIS (Gr. *σύνθεσις*, from *συντιθέναι*, to put together), a term used both generally and technically, with the fundamental meaning of composition, opposed to analysis (*q.v.*), the breaking up of a whole into its component parts. In teaching, for example, when a new fact is brought into connexion with already acquired knowledge and the learner puts them together ("synthesizes"), the result is "synthetic" and the process is "synthesis." The reverse process is analysis, as in grammar when a child breaks up a sentence into subject, verb, object, &c. Thus all inductive reasoning is synthetic in character. The term "synthesis" is much used in philosophy. Thus Kant makes a distinction, fundamental to his theory of knowledge, between analytic and synthetic judgments, the latter being those judgments which are not derivable from the nature of the subject, but in which the predicate is obtained rather by experience or by the operation of the mind (the "synthetic judgment a priori"; see KANT). Perhaps the most famous use of the term is in Herbert Spencer's "Synthetic Philosophy," the name given to the several treatises which contain his philosophic system—the "unification of knowledge" from the data of the separate sciences.

SYNTIPAS, the Greek form of Sindibad or Sendabar, an Indian philosopher supposed to have lived about 100 B.C., and the reputed author of a collection of tales known generally in Europe as the story of the Seven Wise Masters. They enjoyed immense popularity, and appeared in many Oriental and Western languages. A Greek translation (probably from a Syriac version), the earliest specimen of Romaic prose (11th century), is extant under the title of *The most pleasing Story of Syntipas the Philosopher.* It is preceded by an introduction in iambic verse by a certain Michael Andreopulos, who states that it was executed by order of Michael, probably the duke of Melitene in Armenia. The translator is evidently a Christian, although he has generally preserved the Oriental colouring. The main outline is the same in the different versions, although they vary in detail and include different stories. A certain prince, who had taken a vow of silence for a time on the advice of his tutor, was tempted by his stepmother. Her advances having been rejected, she accused him to his father, who decided to put him to death. The device of the *Arabian Nights* is introduced by the wise men of the court, who in turn relate stories to dissuade the king from over-hasty punishment, each story being answered by the queen, who desires instant action to be taken. When the period of silence is over the prince speaks and establishes his innocence. In the Greek version the king is a king of Persia, named Cyrus, and Syntipas himself is the prince's tutor (text in A. Eberhard, *Fabulae Romanenses*, i., 1872, "Teubner Series").

For a discussion of the whole subject, see D. Comparetti, *Ricerche intorno al libro di Sindibad* (1869; Eng. trans. by H. C. Coote, *Folk-Lore Society*, 1882); W. A. Clouston, *The Book of Sindibad* (from the Persian and Arabic, 1884; from the Syriac, by H. Gollancz, 1897); J. C. Dunlop, *Hist. of Prose Fiction* (new ed., 1888), vol. ii.; C. Krumbacher, *Geschichte der byzantinischen Litt.* (2nd ed., 1897). Sixty-two Aesopic fables, also translated from Syriac into Greek, are attributed to this same Syntipas (ed. C. F. Matthäi, 1781).

SYRA, or SYROS (anc. *Σύρος*, perhaps Homeric *Συρίη*), a Greek island in the middle of the Cyclades, which in the 19th century became the commercial centre of the Archipelago, and is also the residence of the nomarch of the Cyclades and the seat of the central law courts. The length of the island is about 10 m., the breadth 5, and the area is estimated at 42½ sq. m. The population rose to about 33,700, of whom about 20,500 were in the chief town, Hermoupolis, but that of the town had in 1907 declined again to 18,132. Syra is also a province of the department of the Cyclades (pop. 1907, 31,939). The importance of the island in prehistoric times is attested by considerable remains of early Aegean antiquities. In ancient times it was remarkably fertile, as is to be gathered not only from the Homeric description (*Od.* xv. 403), which might be of doubtful application, but also from the remains of olive presses and peculiarities in the local nomenclature. The destruction of its forests has led to the loss of all its alluvial soil, and now it is for the most part a brown and barren rock, covered at best with scanty aromatic scrub, pastured by sheep and goats.

Hermopolis (better Hermoupolis), the chief town, is built round the harbour on the east side of the island. It is governed by an active municipality, whose revenue and expenditure have rapidly increased. Among the public buildings are a spacious town-hall in the central square, a club-house, an opera-house and a Greek theatre. Old Syra, on a conical hill behind the port town, is an interesting place, with its old Roman Catholic church of St George's still crowning the summit. This was built by the Capuchins, who in the middle ages chose Syra as the head-quarters of a mission in the East. Louis XIII., hearing of the dangers to which the Syra priests were exposed, took the island under his especial protection, and since that time the Roman Catholic bishops of Syra have been elected by the pope. About the beginning of the 19th century the inhabitants of Syra numbered only about 1000; whenever a Turkish vessel appeared they made off to the interior and hid themselves. On the outbreak of the war of Greek independence refugees from Chios, after being scattered throughout Tenos, Spezia, Hydra, &c., and rejected by the people of Ceos, took up their residence at Syra under the protection of the French flag. Altogether about 40,000 had sought this asylum before the freedom of Greece was achieved. The chief city was called Hermoupolis after the name of the ship which brought the earlier settlers. Most of the immigrants elected to stay, and, though they were long kept in alarm by pirates, they continued to prosper. In 1875 1568 sailing ships and 698 steamers (with a total of 740,731 tons) entered and 1588 sailing ships and 700 steamers (with a total of 756,807 tons) cleared this port; in 1883 3379 sailing and 1126 steam vessels (with a total of 1,056,201 tons) entered and 3276 sailing and 1120 steam vessels (with a total of 960,229 tons) cleared. Most of the sailing vessels were Greek and Turkish, and most of the steamers were Austrian, French and Turkish.

But since the energetic development of Peiraeus, Syra has ceased to be the chief commercial entrepôt and distributing centre of this part of the Levant, and consequently its trade has seriously declined. Whereas in 1890 the foreign commerce was valued at £1,313,730, in 1900 it only amounted to £408,350. Coal, textiles and iron and steel goods figure prominently amongst the imports, and emery, leather, lemons, sponges, flour, valonia and iron ore amongst the exports. Syra is the seat of several industries, ship-building, tanneries, flour and cotton mills, rope-walks, factories for confectionery ("Turkish delight"), hats, kerchiefs, furniture, pottery and distilleries. The harbour, which is protected by a breakwater 273 yds. long, has a depth of 25 ft., diminishing to 12 ft.

SYRACUSE (Gr. Συράκουσαι; Lat. *Syracusae*, Ital. *Siracusa*), a city of Sicily, the capital of a province of the same name, situated on the east coast of the island, 54 m. by rail S. by E. of Catania, and about 32 m. direct. Pop. (1881), 21,739; (1906), 23,250 (town), 35,000 (commune).

History.—Syracuse was the chief Greek city of ancient Sicily, and one of the earliest Greek settlements in the island. According to Strabo (vi. 4, p. 269) Chersicrates and Archias of Corinth, both Heraclidae, left their native city together with a band of colonists, the former stopping with half the force at Corcyra, where he expelled the Liburnians and occupied the island, while Archias proceeded to Syracuse.[1] Thucydides (vi. 3) gives the date as the year after the foundation of Naxos (*i.e.* 734 B.C.), and mentions that Archias expelled the Sicel inhabitants from the island. Their presence there was definitely proved by the discovery in 1905 of a rock-cut tomb of the beginning of the second Sicel period (see SICILY) on the west side of the island (Orsi in *Notizie degli Scavi*, 1905, 381), while similar tombs may be seen both on the north and south edges of the terrace of Epipolae, and on the peninsula of Plemmyrium. There is, on the other hand, no conclusive evidence for the previous existence of a Phoenician settlement on the island,[2] though it is certainly such a place as Thucydides (vi. 2) describes as occupied by them for purposes of trade with the Sicels. The name of the island, Ortygia (ὄρτυξ, a quail), has, again, been held to point to the possible existence of an Aetolian settlement on the island before Archias came. But it is more probable that the name was given to the island owing to the establishment there by the first settlers of a special cult of Artemis (the name Ortygia appears in Homer, *Odyssey*, v. 123, as an island sacred to Artemis, though the identification with Delos (*q.v.*) is not certain), though why Corinthians should have worshipped Artemis in preference to any other deity is not clear.

Till the beginning of the 5th century B.C. our notices of Syracusan history are quite fragmentary. Almost the only question is whether, as some stray notices (see Freeman, *History of Sicily*, ii. 431) might suggest, the primitive kingship was retained or renewed at Syracuse, as it certainly was in some other Greek colonies. A king Pollis is spoken of; but nothing is known of his actions. It is far more certain that Syracuse went through the usual revolutions of a Greek city. The descendants of the original settlers kept the land in their own hands, and they gradually brought the Sicel inhabitants to a state not unlike villenage. Presently other settlers, perhaps not always Greek, gathered round the original Syracusan people; they formed a distinct body, δῆμος or *plebs*, personally free, but with an inferior political franchise or none at all. The old citizens thus gradually grew into an exclusive or aristocratic body, called γαμόροι or landowners. We hear incidentally of disputes, seditions and changes, among others the expulsion of the Gamori early in the 5th century B.C. (Thuc. v. 5; Arist. *Pol.* v. 3, 5; 4, 1). In its external development Syracuse differed somewhat from other Sicilian cities. Although it lagged in early times behind both Gela and Acragas (Agrigentum), it very soon began to aim at a combination of land and sea power.[3] In 663 it founded the settlement of Acrae, in 643 Casmenae,[4] and in 598 Camarina, of which the first was unusually far inland. The three together secured for Syracuse a continuous dominion to the south-east

[1] Strabo goes on to say that Archias fell in with certain men who had come from the Sicilian Megara, and took them with him to share in his enterprise. But this version implies that Megara was founded before Syracuse, which is contrary to all other authorities. The whole question of the various tales relating to the foundation of Syracuse is discussed by E. A. Freeman, *History of Sicily*, i. 335 sqq., 572 sqq.

[2] The origin of the name Συράκουσαι is quite uncertain. It has been suggested that it may be Phoenician: and, again, the plural form has been thought to point perhaps to "the union of two originally distinct posts," one on the island, the other on the mainland on the hill where the ruins of the Olympieum stand, known as πολίχνη—the latter being the original Syracuse.

[3] Netum (Noto) and Helorum, both to the S.S.W. of Syracuse, must have been among its earliest settlements (Freeman ii. 17).

[4] The site of Casmenae is uncertain; it was to the south-west of Syracuse, and not improbably at Spaccaforno (Freeman ii. 25).

coast. They were not strictly colonies but outposts; Camarina indeed was destroyed after a revolt against the ruling city (Thuc. v. 1). Whether the inland Sicel town of Henna was ever a Syracusan settlement is doubtful. It is extremely probable that Acrae was not founded until after two obvious outposts had already been occupied—a post guarding the road to Acrae itself, and including the sacred enclosure of Apollo, which later, when it became a quarter of the city, acquired the name Temenites; and another post on the road to the north, in the upper part of the region known as Achradina. The latter was defended on the north and east by the sea, on the west by a long straight cutting of the rock serving as a scarp on which the wall stood (see below), and on the south by extensive quarries (Freeman ii. 43, 139, 144). About the middle of the 6th century B.C.[1] the island was connected with the mainland by a mole (Freeman ii. 140, 505). At the beginning of the 5th century B.C. Syracusan history becomes far more clear. Hippocrates, tyrant of Gela (498–491), threatened the independence of Syracuse as well as of other cities, and it was saved only by the joint intervention of Corinth and Corcyra and by the cession of the vacant territory of Camarina. In 485 the Gamori, who had been expelled by the Demos and the Sicel serfs, and had taken refuge at Casmenae, craved help of Gelo, the successor of Hippocrates, who took possession of Syracuse without opposition, and made it the seat of his power. He gave citizenship both to mercenaries and to settlers from Greece, and added to the population the inhabitants of other cities conquered by him, so that Syracuse became a city of mixed population, in which the new citizens had the advantage. He then extended the city by including within the fortifications the low ground (or at any rate the western portion of the low ground) between Upper Achradina and the island, and making the Agora there[2]; at the same time (probably) he was able to shift the position of the crossing to the island by making a new isthmus in the position of the present one, the old mole being broken through so as to afford an outlet from the Little Harbour on the east (Lupus, p. 91). The island thus became the inner city, the stronghold of the ruler, so that, despite its low level, it is often spoken of as the "acropolis." Gelo's general rule was mild, and he won fame as the champion of Hellas by his great victory over the Carthaginians at Himera. He is said to have been greeted as king; but he does not seem to have taken the title in any formal way.

Gelo's brother and successor, Hiero (478–467), kept up the power of the city; he won himself a name by his encouragement of poets, especially Aeschylus and Simonides, and philosophers; and his Pythian and Olympian victories made him the special subject of the songs of Pindar and Bacchylides; among the recently discovered works of the latter are three *Odes* (iii.–v.) written for him. He appeared also as a Hellenic champion in the defence of Cumae against the Etruscans, and he attempted after the victory to found a Syracusan colony on the island of Aenaria, now Ischia. But his internal government, unlike that of Gelo, was suspicious, greedy and cruel. After some family disputes the power passed to his brother Thrasybulus, who was driven out next year by a general rising. In this revolution Thrasybulus and his mercenaries held the fortified quarters of Ortygia and Achradina; the revolted people held the unwalled suburbs, already, it is plain, thickly inhabited. Thrasybulus yielded to the common action of Siceliots and Sicels. Syracuse thus became a democratic commonwealth. Renewed freedom was celebrated by a colossal statue of Zeus Eleutherius and by a yearly feast in his honour. But when the mercenaries and other new settlers were shut out from office[3] new struggles arose. The mercenaries again held Ortygia and Achradina. The people now walled in the suburb of Tyche to the west of Achradina (Freeman iii. 306, 312, 456). The mercenaries were at last got rid of in 461. Although we hear of attempts to seize the tyranny and of an institution called *petalism*, like the Athenian ostracism, designed to guard against such dangers, popular government was not seriously threatened for more than fifty years. The part of Syracuse in general Sicilian affairs has been traced in the article SICILY (*q.v.*); but one striking scene is wholly local, when the defeated Ducetius took refuge in the hostile city (451), and the common voice of the people bade "spare the suppliant." We hear of a naval expedition to the Etruscan coast and Corsica about 453 B.C. and of the great military and naval preparations of Syracuse in 439 (Diod. xii. 30). Yet all that we read of Syracusan military and naval action during the former part of the Athenian siege shows how Syracuse had lagged behind the cities of old Greece, constantly practised as they were in warfare both by land and sea.

The Athenian siege (415–13) is of the deepest importance for the topography of Syracuse, and it throws some light on the internal politics. At first complete incredulity prevailed as to the Athenian expedition (Thuc. vi. 32). Hermocrates, the best of counsellors for external affairs, is suspected, and seemingly with reason, of disloyalty to the democratic constitution. Yet he is, like Nicias and Phocion, the official man, head of a board of fifteen generals, which he persuades the people to cut down to three. Athenagoras, the demagogue or opposition speaker, has an excellent exposition of democratic principles put into his mouth by Thucydides (vi. 36–40). Through the whole siege[4] there was a treasonable party within the city, which—for what motives we are not told—kept up a correspondence with the besiegers. When the Athenian fleet under Nicias, Alcibiades and Lamachus was at Rhegium in Italy, after the discovery of the trick that had been played by the Segestans, the question for the commanders was whether they should seek to strengthen themselves by fresh alliances on the spot or strike the blow at once. Lamachus was for immediate action, and there can hardly be a doubt that Syracuse must have fallen before a sudden attack by so formidable an armament in the summer of 415. The Syracusans were neither united nor adequately prepared for effectual defence, and it is perfectly clear that they owed their final deliverance to extraordinary good fortune. Athens had the prize within her grasp, and she lost it wholly through the persistent dilatoriness and blundering of Nicias (*q.v.*). It was at his advice that the summer and autumn of 415 were frittered away, and the siege not begun till the spring of 414. By that time the Syracusans were both in better spirits and better prepared; their troops were better organized, and they had built a wall from north to south across Epipolae, taking in Tyche and Temenites, so as to screen them from attack on the side of Epipolae on the north-west. The effect of this was to bar the enemy's approach and push back his blockading lines, which had to be carried over an inconveniently large extent of ground. They did not, however, occupy Euryelus, at the western extremity of the high ground of Epipolae, and this omission allowed the Athenians to obtain possession of the whole plateau, and to begin the investment of the city. The Syracusans had been at first thoroughly cowed; but they were cowed no longer, and they even plucked up courage to sally out and fight the enemy on the high ground of Epipolae. They were beaten and driven back; but at the suggestion of Hermocrates they carried a counter-work up the slope of Epipolae, which, if completed, would cut in two the Athenian lines and frustrate the blockade. At this point Nicias showed considerable military skill. The Syracusans' work was destroyed by a prompt and well-executed attack; and a second counter-work carried across marshy ground some distance to the south of Epipolae and near to the Great Harbour was also demolished after a sharp action, in which Lamachus fell, an irretrievable loss. However, the blockade on the land side was now almost

[1] Holm and Cavallari (cf. Lupus, *Topographie von Syrakus*, 91) make the construction of the mole and of the wall across it contemporary with the fortification of Achradina in the middle of the 7th century B.C. They also consider that the original west boundary of Achradina ran down to the Little Harbour, so that the southern boundary of Achradina was the sea itself.

[2] Holm and Cavallari (see Lupus, p. 99) are inclined to attribute to him the addition of Tyche to the city.

[3] Diod. xi. 72; cf. Arist. *Pol.* v. 3, 10.

[4] The chief authorities for the siege are Thucydides (bks. vi. and vii.), Diodorus (bk. xiii.) and Plutarch, *Nicias*.

complete, and the Athenian fleet had at the same time entered the Great Harbour. The citizens began to think of surrender, and Nicias was so confident that he neglected to push his advantages. He left a gap to the north of the circular fort which formed the centre of the Athenian lines, the point where Epipolae slopes down to the sea, and he omitted to occupy Euryelus.

The second act of the drama may be said to open with the irretrievable blunder of Nicias in letting the Spartan Gylippus first land in Sicily, and then march at the head of a small army, partly levied on the spot, across the island, and enter Syracuse by way of Epipolae, past Euryelus. Gylippus was felt to be the representative of Sparta, and of the Peloponnesian Greeks generally, and his arrival inspired the Syracusans with the fullest confidence. Just before his arrival a few ships from Corinth had made their way into the harbour with the news that a great fleet was already on its way to the relief of the city. The tables were now completely turned, and we hear of nothing but defeat and disaster for the besiegers till their final overthrow. The military skill of Gylippus enabled the Syracusan militia to meet the Athenian troops on equal terms, to wrest from them their fortified position on Plemmyrium, which Nicias had occupied as a naval station shortly after Gylippus's arrival, and thus to drive them to keep their ships on the low beach between their double walls, to take Labdalum, an Athenian fort on the northern edge of Epipolae, and make a third counter-work right along Epipolae in a westerly direction, to the north of the circular fort. The Athenians were thus reduced to such a plight that, as Nicias said in his despatch towards the close of 414, they were themselves besieged rather than besieging. The naval preparations of the Syracusans, under the advice of Hermocrates, had led them, too, to confidence in their powers of giving battle to the Athenian fleet. In the first sea-fight, which took place simultaneously with the capture of Plemmyrium, they had been unsuccessful; but in the spring of 413 they actually won a victory over the Athenians in their own element.

On the very next day, however, a second Athenian fleet arrived under Demosthenes and Eurymedon, with seventy-three ships of war and a large force of heavy infantry and light troops. The despatch of this expedition seems to prove an almost blind confidence in Nicias, whose request to be superseded the Athenian people refused to grant. Demosthenes decided at once to make a grand attack on Epipolae, with a view to recovering the Athenian blockading lines and driving the Syracusans back within the city walls. The assault was made by night by way of Euryelus under the uncertain light of the moon, and this circumstance turned what was very nearly a successful surprise into a ruinous defeat. The affair seems to have been well planned up to a certain point, and well executed; but the Athenian van, flushed with a first success, their ranks broken and disordered by a pursuit of the enemy over rough ground, were repulsed with great loss by a body of heavy-armed Boeotians, and driven back in disorder. The confusion spread to the troops behind them, and the action ended in wild flight and slaughter. The army was now thoroughly out of heart, and Demosthenes was for at once breaking up the camp, embarking the troops, and sailing back to Athens. (It must be remembered that the Spartans were all this time in occupation of Deceleia; see PELOPONNESIAN WAR.) But Nicias could not bring himself to face the Athenian people at home, nor could he be prevailed on to retire promptly to some position on the coast, such as Catania or Thapsus. He dallied till the end of August, many weeks after the defeat, when the coming of Syracusan reinforcements decided him to depart; but on the 27th of that month was an eclipse of the moon, on the strength of which he insisted on a delay of almost another month. His fleet, too, lingered uselessly in the harbour, till after a defeat in which Eurymedon perished, though the simultaneous land attack was unsuccessful. The Syracusans now blocked the mouth of the Great Harbour, and the Athenian fleet, after a frantic effort to break out and a desperate conflict, was utterly defeated and half destroyed. The broken and demoralized army, its ranks thinned by fever and sickness, at last began its hopeless retreat, attempting to reach Catania by a circuitous route; but, harassed by the numerous Syracusan cavalry and darters, after a few days of dreadful suffering, it was forced to lay down its arms. The Syracusans sullied the glory of their triumph by putting Nicias and Demosthenes to death, and huddling their prisoners into their stone-quarries—a living death, dragged out, for the allies from Greece proper to the space of seventy days, for the Athenians themselves and the Greeks of Sicily and Italy for six months longer. Games called Assinarian, from the name of the river at which the final surrender occurred, were instituted to commemorate it.

Her great deliverance and victory naturally stirred up the energies of Syracuse at home and abroad. Syracusan and Selinuntine ships under Hermocrates now play a distinguished part in the warfare between Sparta and Athens on the coast of Asia. Under the influence of Diocles the constitution became a still more confirmed democracy, some at least of the magistracies being filled by lot, as at Athens (Diod. xiii. 31, 35; Arist. *Pol.* v. 3–6). Diocles appears also as the author of a code of laws of great strictness, which was held in such esteem that later lawgivers were deemed only its expounders. Under these influences Hermocrates was banished in 409; he submitted to the sentence, notwithstanding the wishes of his army. He went back to Sicily, warred with Carthage on his own account, and brought back the bones of the unburied Syracusans from Himera, but was still so dreaded that the people banished Diocles without restoring him. In 407 he was slain in an attempt to enter the city, and with him was wounded one who was presently to outstrip both rivals.

This was Dionysius (the "Elder"), son of another Hermocrates and an adherent of the aristocratic party, but soon afterwards a demagogue, though supported by some men of rank, among them the historian Philistus (Diod. xiii. 91, 92). By accusing the generals engaged at Acragas in the war against Carthage, by obtaining the restoration of exiles (no doubt others of the partisans of Hermocrates), by high-handed proceedings at Gela, he secured his own election first as one of the generals, then as sole general (or with a nominal colleague), with special powers. He next, by another trick, procured from a military assembly at Leontini a vote of a bodyguard; he hired mercenaries and in 406–405 came back to Syracuse as tyrant of the city (Diod. xiii. 91–96). Dionysius kept his power till his death thirty-eight years later (367). But it was well-nigh overthrown before he had fully grasped it. His defeat before Gela and his consequent decision that both Gela and Camarina should be evacuated, and left for the Carthaginians to plunder, were no doubt due to previous arrangement with the latter. His enemies in the army, chiefly the horsemen, reached Syracuse before him, plundered his house, and horribly maltreated his wife. He came and took his vengeance, slaying and driving out his enemies, who established themselves at Aetna (Diod. xiii. 113). In 397 Syracuse had to stand a siege from the Carthaginians under Himilco, who took up his quarters at the Olympieum, but his troops in the marshes below suffered from pestilence, and a masterly combined attack by land and sea by Dionysius ended in his utter defeat. Dionysius, however, allowed him to depart without further pressing his advantage. This revolution and the peace with the Carthaginians confirmed Dionysius in the possession of Syracuse, but of no great territory beyond, as Leontini was again a separate city. It left Syracuse the one great Hellenic city of Sicily, which, however enslaved at home, was at least independent of the barbarian. Dionysius was able, like Gelo, though with less success and less honour, to take up the rôle of the champion of Hellas.

During the long tyranny of Dionysius the city grew greatly in size, population and grandeur. In fact the free Greek cities and communities, in both Sicily and southern Italy, were sacrificed to Syracuse; there the greatness and glory of the Greek world in the West were concentrated. The mass of the population of Gela and Camarina in the disastrous year 405 had, at the prompting of Dionysius, taken refuge at Syracuse. Gela had in the previous year received the fugitive inhabitants of Acragas (Agrigentum), which had been sacked by the

Carthaginians. Syracuse thus absorbed three of the chief Greek cities of Sicily. It received large accessions from some of the Greek cities of southern Italy, from Hipponium on its west and Caulonia on its east coast, both of which Dionysius captured in 389 B.C. There had also been an influx of free citizens from Rhegium. At the time of the Athenian siege Syracuse consisted of two quarters—the island and the "outer city" of Thucydides, generally known as Achradina, and bounded by the sea on the north and east, with the adjoining suburbs of Apollo Temenites farther inland, at the foot of the southern slopes of Epipolae and Tyche west of the north-west corner of Achradina. Dionysius largely extended the fortifications. The island (Ortygia) had been provided with its own defences, converted, in fact, into a separate stronghold, with a fort to serve specially as a magazine of corn, and with a citadel or acropolis which stood apart and might be held as a last refuge. Dionysius, to make himself perfectly safe, drove out a number of the old inhabitants and turned the place into a barracks, he himself living in the citadel. For any unpopularity he may have thus incurred he seems to have made up by his great works for the defence of the city. Profiting by the experience gained during the Athenian siege, he included in his new lines the whole plateau of Epipolae, with a strong fortress at Euryelus, its apex on the west; the total length of the outer lines (excluding the fortifications of the island) has been calculated at about 12 m. The material (limestone) was quarried on the spot. Each quarter of the city had its own distinct defences, and Syracuse was now the most splendid and the best fortified of all Greek cities. Its naval power, too, was vastly increased; the docks were enlarged; and 200 new warships were built. Besides the triremes, or vessels with three banks of oars, we hear of quadriremes and quinqueremes with four and five banks of oars—larger and taller and more massive ships than had yet been used in Greek sea warfare. The fleet of Dionysius was the most powerful in the Mediterranean. It was doubtless fear and hatred of Carthage, from which city the Greeks of Sicily had suffered so much, that urged the Syracusans to acquiesce in the enormous expenditure which they must have incurred under the rule of Dionysius. Much, too, was done for the beauty of the city as well as for its strength and defence. Several new temples were built, and gymnasia erected outside the walls near the banks of the Anapus (Diod. xv. 13).

"Fastened by chains of adamant" was the boastful phrase in which Dionysius described his empire; but under his son, the younger Dionysius—an easy, good-natured, unpractical man—a reaction set in amongst the restless citizens of Syracuse, which, with its vast and mixed populations, must have been full of elements of turbulence and faction. But the burdensome expenditure of the late reign would be enough to account for a good deal of discontent. A remarkable man now comes to the front—Dion, the friend and disciple of Plato—and for a time the trusted political adviser of his nephew Dionysius. Dion's idea seems to have been to make Dionysius something like a constitutional sovereign, and with this view he brought him into contact with Plato. All went well for a time; but Dionysius had Philistus and others about him, who were opposed to any kind of liberal reform, and the result was the banishment of Dion from Syracuse as a dangerous innovator. Ten years afterwards, in 357, the exile entered Achradina a victor, welcomed by the citizens as a deliverer both of themselves and of the Greeks of Sicily generally. A siege and blockade, with confused fighting and alternate victory and defeat, and all the horrors of fire and slaughter, followed, till Dion made himself finally master of the mainland city. Ortygia, provisions failing, was also soon surrendered. Dion's rule lasted only three years, for he perished in 354 by the hand of a Syracusan assassin. It was, in fact, after all his professions, little better than a military despotism. The tyrant's stronghold in the island was left standing.

Of what took place in Syracuse during the next ten years we know but little. The younger Dionysius came back and from his island fortress again oppressed the citizens; the plight of the city, torn by faction and conflicts and plundered by foreign troops, was so utterly wretched that all Greek life seemed on the verge of extinction (Plato, *Epist.* viii.). Sicily, too, was again menaced by Carthage. Syracuse, in its extremity, asked help from the mother-city, Corinth; and now appears on the scene one of the noblest figures in Greek history, Timoleon (*q.v.*). To him Syracuse owed her deliverance from the younger Dionysius and from Hicetas, who held the rest of Syracuse, and to him both Syracuse and the Sicilian Greeks owed a decisive triumph over Carthage and the safe possession of Sicily west of the river Halycus, the largest portion of the island. From 343 to 337 he was supreme at Syracuse, with the hearty good will of the citizens. The younger Dionysius had been allowed to retire to Corinth; his island fortress was destroyed and replaced by a court of justice. Syracuse rose again out of her desolation—grass, it is said, grew in her streets—and, with an influx of a multitude of new colonists from Greece and from towns of Sicily and Italy, once more became a prosperous city. Timoleon, having accomplished his work, accepted the position of a private citizen, though, practically, to the end of his life he was the ruler of the Syracusan people. After his death (337) a splendid monument, with porticoes and gymnasia surrounding it, known as the Timoleonteum, was raised at the public cost to his honour.

In the interval of twenty years between the death of Timoleon and the rise of Agathocles (*q.v.*) to power another revolution at Syracuse transferred the government to an oligarchy of 600 leading citizens. All we know is the bare fact. It was shortly after this revolution, in 317, that Agathocles with a body of mercenaries from Campania and a host of exiles from the Greek cities, backed up by the Carthaginian Hamilcar, who was in friendly relations with the Syracusan oligarchy, became a tyrant or despot of the city, assuming subsequently, on the strength of his successes against Carthage, the title of king. Syracuse passed through another reign of terror; the new despot proclaimed himself the champion of popular government, and had the senate and the heads of the oligarchical party massacred wholesale. He seems to have had popular manners, for a unanimous vote of the people gave him absolute control over the fortunes of Syracuse. His wars in Sicily and Africa left him time to do something for the relief of the poorer citizens at the expense of the rich, as well as to erect new fortifications and public buildings; and under his strong government Syracuse seems to have been at least quiet and orderly. After his death in 289 comes another miserable and obscure period of revolution and despotism, in which Greek life was dying out; and but for the brief intervention of Pyrrhus in 278 Syracuse, and indeed all Sicily, would have fallen a prey to the Carthaginians.

A better time began under Hiero II., who had fought under Pyrrhus and who rose from the rank of general of the Syracusan army to be tyrant—king, as he came to be soon styled—about 270. During his reign of over fifty years, ending probably in 216, Syracuse enjoyed tranquillity, and seems to have grown greatly in wealth and population. Hiero's rule was kindly and enlightened, combining good order with a fair share of liberty and self-government. His financial legislation was careful and considerate; his laws[1] as to the customs and the corn tithes were accepted and maintained under the Roman government, and one of the many bad acts of the notorious Verres, according to Cicero, was to set them aside (Cic. *In Verr.* ii. 13, iii. 8). It was a time, too, for great public works—works for defence at the entrance of the Lesser Harbour between the island and Achradina, and temples and gymnasia. Hiero through his long reign was the stanch friend and ally of Rome in her struggles with Carthage; but his paternal despotism, under which Greek life and civilization at Syracuse had greatly flourished, was unfortunately succeeded by the rule of a man who wholly reversed his policy.

Hieronymus, the grandson of Hiero, thought fit to ally himself with Carthage; he did not live, however, to see the mischief he had done, for he fell in a conspiracy which he had wantonly provoked by his arrogance and cruelty. There was a fierce

[1] The laws of Hiero are often mentioned with approval in Cicero's speeches against Verres.

popular outbreak and more bloodshed; the conspirators were put to death and Hiero's family was murdered; whilst the Carthaginian faction, under the pretence of delivering the city from its tyrants, got the upper hand and drew the citizens into open defiance of Rome. M. Claudius Marcellus was then in command of the Roman army in Sicily, and he threatened the Syracusans with attack unless they would get rid of Epicydes and Hippocrates, the heads of the anti-Roman faction. Epicydes did his best to stir up the citizens of Leontini against Rome and the Roman party at Syracuse. Marcellus, therefore, struck his first blow at Leontini, which was quickly stormed; and the tale of the horrors of the sack was at once carried to Syracuse and roused the anger of its population, who could not but sympathize with their near neighbours, Greeks like themselves. The general feeling was now against any negotiations with the Roman general, and, putting themselves under Epicydes and Hippocrates, they closed their gates on him. Marcellus, after an unsuccessful attempt to negotiate, began the siege in regular form (214 B.C.) by both land and sea, establishing a camp on Polichne, where stood the old temple of Olympian Zeus; but he made his chief assault on the northern side and on the defences of Tyche, particularly at the Hexapylum, the entrance facing Megara and Leontini. His assault seawards was made mainly on Achradina,[1] but the city was defended by a numerous soldiery and by what seems to have been still more formidable, the ingenious contrivances of Archimedes, whose engines dealt havoc among the Roman ships, and frustrated the attack on the fortifications on the northern slopes of Epipolae (Liv. xxiv. 34). Marcellus had recourse to a blockade, but Carthaginian vessels from time to time contrived to throw in supplies. At length treachery began to work within. Information was given him in the spring of 212 (two years from the commencement of the siege) that the Syracusans were celebrating a great festival to Artemis; making use of this opportunity, he forced the Hexapylum entrance by night and established himself in Tyche and on the heights of Epipolae. The strong fortress of Euryelus held out for a time, but, being now isolated, it soon had to surrender. The "outer" and the "inner" city of Thucydides still held out, whilst a Carthaginian fleet was moored off Achradina and Carthaginian troops were encamped on the spot. But a pestilence broke out in the autumn of 212, which swept them clean away, and thinned the Roman ranks. The ships sailed away to Carthage; on their way back to Syracuse with supplies they could not get beyond Cape Pachynus owing to adverse winds, and they were confronted by a Roman fleet. All hope for the city being now at an end, the Syracusans threw themselves on the mercy of Marcellus; but Achradina and the island still held out for a brief space under the Syracusan mercenaries, till one of their officers, a Spaniard, betrayed the latter position to the enemy, and at the same time Achradina was carried and taken. Marcellus gave the city up to plunder (Liv. xxv. 31), and the art treasures in which it was so rich—many of the choicest of them, no doubt—were conveyed to Rome. Archimedes perished in the confusion of the sack while he was calmly pursuing his studies (Liv. xxv. 31).

Syracuse was now simply one of the provincial cities of Rome's empire, and its history is henceforward merged in that of Sicily. It retained much of its Greek character and many of its finest public buildings, even after the havoc wrought by Marcellus. Its importance and historic associations naturally marked it out as the residence of the Roman praetor or governor of Sicily. Cicero often speaks of it as a particularly splendid and beautiful city, as still in his own day the seat of art and culture (*Tusc.* v. 66; *De deor. nat.* iii. 81; *De rep.* i. 21), and in his speeches against Verres (iv. 52, 53) he gives an elaborate description of its four quarters (Achradina, Neapolis, Tyche, the island). It seems to have suffered in the civil wars at the hands of Sextus Pompeius, the son of the triumvir, who for a short time was master of Sicily; to repair the mischief, new settlers were sent by Augustus in 21 B.C., and established in the island and in the immediately adjoining part of Achradina (Strabo vi. 270). It was he who probably constructed the amphitheatre. Tacitus, in a passing mention of it (*Ann.* xiii. 49), says that permission was granted to the Syracusans under Nero to exceed the prescribed number of gladiators in their shows. Caligula restored its decayed walls and some of its famous temples (Suetonius, *Calig.* 21). In the 4th century it is named by the poet Ausonius in his *Ordo nobilium urbium*, chiefly, perhaps, on the strength of its historic memories. In 665 Heraclius Constans fixed his capital here, but owing to his oppressive government was assassinated in 668. Syracuse has been a place of comparatively little importance since the year 878, when it was destroyed by the Saracens under Ibrahim ibn Ahmad.

Archaeology.—The medieval and modern town of Syracuse (with the exception of a new quarter which has sprung up since the construction of the railway between the station and the island) is confined to the island. This contains the remains of two Doric temples. The older, belonging probably to the beginning of the 6th century B.C., appears, from an inscription on the uppermost step, to have been dedicated to Apollo. It was a peripteral hexastyle, and must have had at least nineteen columns at the sides; the portion excavated shows that its total width is 74¼ ft., the width of the cella 38½ ft., the lower diameter of the columns 6¼ ft. The other temple, into which the cathedral was built in A.D. 640, is to be dated after 440 B.C. It was a peripteral hexastyle of thirty-six columns, with a total length of 160½ ft. and a total breadth of 72 ft.; the columns have a lower diameter of 5¾ ft., and the inter-columniation is 13½ ft. It is generally regarded as the temple of Athena.

Near the west coast of the island is the famous fountain of Arethusa.[2] According to the legend, the nymph Arethusa was changed into the fountain by Artemis to deliver her from the pursuit of the river-god Alpheus (*q.v.*); and the spring, which was fresh until an earthquake broke the barrier and let in the salt water, was supposed to be actually connected with the river. There are interesting remains of medieval architecture in the closely built town with its narrow streets; the beautiful 14th-century windows of the Palazzo Montalto may be especially noticed, and also the 13th-century Castello Mainace at the southern extremity of the island. The town also contains the archaeological museum, which, under the direction of Professor Orsi, is now the best arranged in the island. The discoveries of recent years in the south-eastern portion of Sicily, including especially the objects found in Sicel and Greek cemeteries, may be studied here. The isthmus connecting the island with the mainland, which was defended by strong fortifications erected by Charles V. and Philip II. (now demolished), does not occupy the site of the mole erected in the 6th or 7th century B.C., which may be recognized as having run due north from the north point of the island to the mainland near the ferry of S. Lucia.[3] The Little Harbour was thus in origin merely a recess of the Great Harbour; and it was probably Gelo who was responsible for making it an independent port, by establishing the crossing to the island in its present position. On the landward side of the new isthmus was the Agora, in which remains of a colonnade of the Roman period have been found. To the west are the remains of an extensive building of the Roman period, probably a palaestra, with a small Odeum attached. To the W.N.W. is the so-called Piano del Fusco, an extensive necropolis, in which over six hundred tombs, mostly of the 7th and 6th centuries B.C., have been found.[4] This necropolis was included within the defensive wall of Dionysius, a portion of which, no less than 18½ ft. thick, was found in 1886 running diagonally across the new cemetery, and in 1903 an outwork in front of it was discovered (P. Orsi, in *Notizie degli scavi*, 1903, 517). East of this point it probably followed the edge

[1] This statement made by Polybius (viii. 5) is almost incredible. Livy's account of the siege, too, is full of topographical difficulties (Lupus, 214 sqq.).

[2] The name is a widespread Greek name for a spring.

[3] Lupus, *Topographie von Syrakus*, 26, 88, 91. Near the ferry are a row of long parallel cuttings in the rock, which must be remains of the ancient docks, each being intended to take a ship.

[4] It is remarkable that hardly any tombs of the 5th century B.C. have come to light.

of the low terrace above the marsh (the ancient Lysimeleia),[1] while in the other direction it ran N.N.W., making straight for the western edge of the gorge known as the Portella del Fusco, which was thus included within the fortifications, as it would otherwise have afforded a means of access to the enemy. Here the wall gained the top of the cliffs which mark the southern edge of the plateau of Epipolae, which from this point onwards it followed as far as Euryelus. The south wall of Epipolae, considerable remains of which exist, shows traces of different periods in its construction, and was probably often restored.[2] It is built of rectangular blocks of limestone generally quarried on the spot, about $5\frac{3}{4}$ ft. long, 2 ft. high and $2\frac{1}{2}$ ft. deep. The thickness of the wall averages 10 ft., but varies 3 or 4 ft. each way. The point where the terrace of Epipolae narrows down to a ridge about 60 yds. wide, which is its only link with the hills to the west, had thrice proved during the Athenian siege to be the key to Syracuse. It now bears the ruins of a mighty fortress, finer than that which defends the entrance to the acropolis of Selinus—the most imposing, indeed, that has come down to us from the Greek period—which there is no doubt is the work of Dionysius. The total length of the works is about 440 yds. In front of the castle proper are three ditches, the innermost of which can be reached from the interior of the castle by a complicated system of underground passages. The front of the castle is formed by five massive towers: behind it are two walled courtyards, to the north of the easternmost of which is the well-guarded main entrance to the plateau of Epipolae (narrower minor entrances are to be seen on both the north and the south sides) communicating by a long underground passage with the inner ditch in front of the castle proper. That this point is to be identified with Euryelus is now generally admitted (see Lupus, 125–127; Freeman, iii. 661). Earlier writers make this the site of Labdalum, and put Euryelus farther west; but Labdalum must be sought somewhat farther east, near the northern edge of the plateau, in a point not visible from the Athenian central fort (*κύκλος*) with a view over Megara —not therefore in the commanding position of Dionysius's fort, with an uninterrupted view on all sides. On the north side of Epipolae the cliffs are somewhat more abrupt; here the wall, of a similar construction to that on the south, is also traceable: but here it is apparently all of one period. It is, indeed, recorded by Diodorus that Dionysius built the north wall from Euryelus to the Hexapylon in twenty days for a length of $2\frac{3}{4}$ m., employing 60,000 peasants and 6000 yoke of oxen for the transport of the blocks. Several smaller entrances are to be seen in it, as in the south wall: among them one with a series of inclined planes cut in the rock, which leads to an ancient road running south-east to the neighbourhood of the theatre. The Hexapylon plays an important part in the Roman siege of Syracuse. It was the main entrance on the north, and no doubt is to be identified with the so-called Scala Greca, where the modern highroad leaves the plateau.[3] This highroad, which probably follows an ancient line, may be reasonably held to mark the west boundary of Tyche. Five hundred yards to the east of it an interesting postern was discovered in 1895 (Orsi, in *Notizie degli scavi*, 1893, 168), at the point where the wall leaves the edge of the plateau and begins to follow the sea-coast; and half a mile farther on we reach the deep gorge of S. Bonagia (more correctly Panagia), which here forms the boundary between Tyche and Achradina. The west boundary of Achradina is marked farther south by a perpendicular cutting in the rock, on the top of which a wall must have run (see above). To the east of the gorge the wall still follows the edge of low cliffs of the coast, and continues to do so all along the east side of Achradina as far as the Little Harbour. On this side traces of it are very scanty, as the sea-spray has eaten away the stone.

The most important buildings of which we have any remains are to be found in the lower part of Achradina and in Neapolis, a quarter of which we hear first in the time of Dionysius, and which at first was confined to the lower ground below Temenites, but in Roman times included it and the theatre also (Lupus, 168), though it did not extend beyond the theatre to the uppermost part of the plateau. In lower Achradina remains of Roman private houses have been found, and it is in this district that the early Christians[4] constructed their catacombs. Those which are entered from near the 12th-century church of S. Giovanni, situated near an ancient temple, are extensive and important, and include the ancient crypt of S. Marcianus, and the type is different from that of the Roman catacombs, the galleries being far larger (partly owing to the hardness of the limestone in which they are excavated), and having circular chambers at the points of junction. In Neapolis, on the other hand, public buildings predominate. The temple of Apollo Temenites has entirely disappeared, but the theatre, entirely hewn in the rock, is still to be seen. It is the largest in Sicily, being about 146 yds. in diameter, and having about sixty rows of seats; the eleven lower tiers were originally covered with marble. Each of the nine *cunei* bore a name: the inscriptions of five of them, still preserved on the rock, are in honour of Zeus, Heracles, King Hiero II., his wife Philistis, and his daughter-in-law Nereis. Of the stage nothing but cuttings in the rock for foundations are visible. The situation is well chosen, commanding a splendid view over the Great Harbour. Not far off to the south-east is the amphitheatre, probably erected by Augustus when he founded a colony at Syracuse; it is partly cut in the rock and partly built. It is inferior in size only to the Colosseum and the amphitheatres of Capua and Verona, measuring about 153 by 130 yds. over all: the arena is 76 by 43 yds. To the west of the amphitheatre is the foundation of the great altar erected by Hiero II. (Diod. xvi. 83), 217 yds. long by 24 wide, and about 6 yds. in height. To the north-west of the theatre a winding road ascends through the rock, with comparatively late tomb chambers on each side of it. In this district are seen hundreds of small niches cut in the rock, as a rule about 2 ft. square and a few inches deep, which served for containing inscriptions or reliefs, sometimes of a sepulchral character, but sometimes relating to the cult of a divinity. Many of them are also found in the quarries (Orsi, in *Notizie degli scavi*, 1904, 277). Both the districts just described also contain huge quarries, the famous Lautumiae (from Gr. λᾶας, stone, and τεμεῖν, to cut; hence λατομία, quarry) of Syracuse, over 100 ft. deep and of great extent (though through the collapse of the pillars supporting the undermined rock they have become still larger than they were in ancient times). They are now overgrown with luxuriant vegetation. The upper plateau (Achradina, Tyche, Epipolae itself) is now largely cultivated at the east end, less so at the west end. It is traversed by the subterranean aqueducts by which the city was supplied[5] (see AQUEDUCTS), and by a few ancient roads, but contains practically no remains of ancient buildings. Cuttings in the rock for the foundations of such are numerous round the south edge of Temenites and Achradina, and are to be seen at various points near the city wall. But otherwise the disappearance of the edifices of ancient Syracuse is most striking.

We have already seen that immediately outside Lower Neapolis on the south the marshes of Lysimeleia begin, which proved fatal to more than one besieging force. They are traversed by the Anapus, with its tributary the Cyane, the latter famous for the papyrus planted by the Arabs, which here alone in Europe grows wild in the stream. To the south of the Anapus is the hill of Polichne, on which stood the Olympieium, attributed on stylistic grounds to 581 B.C. Its monolithic

[1] The date of the fragment of city wall immediately to the north-east of the so-called palaestra is uncertain; it is therefore doubtful whether it can belong to this system of defences (Lupus, pp. 308, 331).

[2] As to the question whether it was finished at the time of the Carthaginian invasion of 397 B.C., see Freeman, iv. 55. In any case it must have been completed by 385 B.C.

[3] Here are numerous caves in the rock, used for the worship of Artemis.

[4] St Paul tarried at Syracuse three days on his way to Rome (Acts xxviii. 12).

[5] A large reservoir of the Greek period exists under the present railway station (*Notizie degli scavi*, 1904, 280).

columns, of which two are still standing, are about 21 ft. in height and 6 ft. in lower diameter: its length is estimated at 197 ft., its breadth at 66¾ ft. (Orsi, in *Monumenti dei Lincei*, 1903, xiii. 369). The hill was frequently occupied in attacks on Syracuse by the besieging force. It is not, however, defensible in the rear: hence Dionysius's success against the Carthaginians. The hill of Dascon is to be sought a trifle to the south-east, to the south of the mouth of the Anapus, on the edge of the Great Harbour, at the Punta Caderini. From this point southwards the shore of the Great Harbour, previously low and marshy, begins to rise, until the rocky promontory of Plemmyrium is reached, which closes it on the south. Here Sicel tombs have been found, in some of which it appears that the Athenian dead were hastily buried (Freeman iii. 365, n. 1), while a colossal tomb, attributable also to the time of the Athenian invasion, was found there in 1899.

See A. Holm and F. S. and C. Cavallari, *Topografia archeologica di Siracusa* (Palermo, 1883), or the more handy German translation by B. Lupus, *Topographie von Syrakus* (Strassburg, 1887); P. Orsi, in *Atti del congresso di scienze storiche*, v. 181 (Rome, 1904), and in *Notizie degli scavi, passim*; E. Mauceri, *Siracusa* (Palermo, 1904); J. Führer and V. Schultze, "Die altchristlichen Grabstätten Siziliens," *Jahrbuch des k. d. arch. Inst.*; Ergänzungsheft, vii. 17 sqq. (Berlin, 1907). In the hills to the west of Syracuse many Sicel villages must have existed; cemeteries of the second and third period have been found at Pantalica 15 m. to the north-west, with the ruins of the habitation of the chief of the tribe, and of the second at Cassibile, 10 m. S.S.W. (see Orsi in *Monumenti dei Lincei* (1899) ix. 33, 146). (E. A. F.; T. As.)

SYRACUSE, a city and the county-seat of Onondaga county, New York, U.S.A., situated at the southern end of Onondaga Lake, about 75 m. E. of Rochester and about 150 m. W. of Albany. Pop. (1880), 51,792; (1890), 88,143; (1900), 108,374, of whom 23,757 were foreign-born (including 7865 German, 5717 Irish, 2393 English Canadian and 2383 English) and 1034 were negroes; (1910, census), 137,249. Area (1906), 16·62 sq. m. Syracuse is served by the New York Central & Hudson River, the West Shore, and the Delaware, Lackawanna & Western railways, by the Erie Canal and the Oswego Canal, which joins the Erie within the city limits, and by several electric inter-urban lines. The city is built on high ground in an amphitheatre of hills surrounding the lake, which is a beautiful body of clear water, 5 m. long by 1½ m. broad at its widest point. Of the residential streets, James Street, in the north-eastern part of the city, is the most attractive. Salina Street is the principal business thoroughfare. The park system comprises more than fifty parks and squares, with a total area of 278 acres. The largest and most noteworthy are Burnet park (about 100 acres), on high land in the western part of the city, Lincoln park, occupying a heavily wooded ridge in the east, and Schiller, Kirk and Frazer parks. A boulevard runs along the shore of the lake. A fine water-supply controlled by the city is obtained from Skaneateles Lake, 18 m. distant, by a gravity system which cost $5,000,000; and the city has an intercepting sewer system.

Among the most noteworthy churches of Syracuse are the Roman Catholic cathedral of the Immaculate Conception—Syracuse became the see of a Roman Catholic bishop in 1887—and St Paul's Protestant Episcopal, the first Presbyterian, first Methodist Episcopal, Dutch Reformed and May Memorial (Unitarian) churches, the last erected in memory of Samuel Joseph May (1797–1871), a famous anti-slavery leader, pastor of the church in 1845–1868, and author of *Some Recollections of Our Anti-Slavery Conflict* (1873). Among the public buildings are the Federal Building, the Onondaga county courthouse, costing $1,500,000 and containing a law library of 15,000 vols., the city-hall, the Central high school, a fine building erected at a cost of $400,000, the North high school ($300,000), and the public library (Carnegie) with 60,000 volumes in 1908 and housing the Museum of Fine Arts (1897), also.

Among the hospitals and charitable institutions are the Syracuse hospital (1872) for infectious diseases, the Hospital of the Good Shepherd (1873), the Syracuse homoeopathic hospital (1895), the Syracuse hospital for women and children (1887), St Mary's infant and maternity hospital (1900) under the Sisters of Charity, St Joseph's hospital (1869) under Sisters of the Third Order of St Francis, the Syracuse home for aged women (1852), Onondaga county orphan asylum (private; 1841), and two other orphan asylums controlled by the Sisters of Charity, and the state institution for feeble-minded children (1896). The University block (an office building owned by Syracuse University), the Union Building, the Onondaga county savings bank and the Syracuse savings bank are among the most notable business structures; and the Onondaga, the Vanderbilt House and the Yates and St Cloud hotels are the principal hotels. In Jamesville, about 6 m. south, is the Onondaga penitentiary. Adjacent to the city is Oakwood cemetery, overlooking the lake; and north-west of the city are the state fair grounds, with extensive exhibition halls and barns, where the annual fairs of the New York State Agricultural Society are held. Six miles south of the city is the Onondaga Indian reservation, the present capital of the "Six Nations." The city has an annual carnival and a musical festival.

Syracuse University, whose campus (of 100 acres) in the south-east part of the city commands a fine view of the lake, is a co-educational institution largely under Methodist Episcopal control, but not sectarian, which in 1908–1909 had 239 instructors and 3205 students (1336 in the college of liberal arts; 189 in the summer school; 62 in the library school; 933 in the college of fine arts; 147 in the college of medicine; 179 in the college of law; 401 in the college of applied science; and 78 in the teachers' college). The university was opened in 1871, when the faculty and students of Genesee College (1850) removed from Lima (New York) to Syracuse—a court-ruling made it impossible for the corporation to remove; in 1872 the Geneva medical college (1835) removed to Syracuse and became a college of the university. The courses in library economy (college of liberal arts) are particularly well known. The university library (about 80,000 bound volumes and 40,000 pamphlets) includes (since 1887) the collection of the German historian, Leopold von Ranke. There are seventeen buildings, among which the Holden observatory, the John Crouse memorial college (of fine arts), the hall of languages, the Lyman Smith college of applied science, the Lyman hall of natural history, the Bowne hall of chemistry, and the Carnegie library, are the most notable. There are a large gymnasium and a stadium of re-enforced concrete for athletic contests, capable of seating 20,000 people and one of the largest athletic fields in the world. The plant of the university in 1909 was valued at $3,193,128, and in 1908–1909 its productive funds amounted to about $2,000,000 and its income from all sources was about $784,000.

Other educational institutions are the Syracuse Teachers' training school, Christian Brothers' academy (Roman Catholic), St John's Catholic academy, Travis preparatory school (non-sectarian), and at Manlius (pop. 1910, 1314), a suburb, St John's military academy (Protestant Episcopal, 1869). The Onondaga Historical Association was organized in 1862, and after 21 years of inactivity was reorganized in 1892; it occupies its own building; its committee on natural science developed (1896) into the Onondaga academy of science. Several educational journals are published at Syracuse. There are three daily newspapers, the *Post-Standard* (*Standard*, 1829; *Post*, 1894; consolidated, 1899, Republican), *Journal* (1839; daily since 1844, Republican, and *Evening Herald* (1877), Independent).

The government is that of all cities of the second class in New York state, with an elective mayor and other important officers and a single-chambered city council.

Power from Niagara Falls is used by factories in the city, and the manufactures are extensive and greatly diversified. In 1905 the aggregate capital of the city's manufacturing industries was $38,740,651, and the value of its factory products was $34,823,751, 31·2% more than in 1900. The principal products in 1905 were: men's and women's clothing ($3,527,494, of which $3,082,052 represented men's clothing), foundry and machine-shop products, of which agricultural implements and machinery constituted the greater part ($2,415,466), iron and steel products ($2,117,585), chemicals, malt liquors ($1,960,466), typewriters and typewriting supplies ($1,553,113), and boots and shoes ($1,253,982). Other important products were automobiles and sewing machines, hosiery and knit goods, candles, furniture, flour, crockery, and canned goods (especially mince-meat).

Syracuse was long the principal seat of the salt industry in America.

The Onondaga salt deposits were mentioned in the journal of the French Jesuit Lemoyne as early as 1653, and before the War of Independence the Indians marketed Onondaga salt at Albany and Quebec. In 1788 the state undertook, by treaty with the Onondaga Indians, to care for the salt springs and manage them for the benefit of both the whites and the Indians. In 1795, by another treaty, the state acquired for $1000, to be supplemented by an annual payment of $700 and 150 bushels of salt, the salt springs and land about them covering about 10 sq. m. In 1797 the state leased the lands, the lessees paying a royalty of 4 cents per bushel and being forbidden to charge more than 60 cents per bushel. The state sank wells and built and maintained tanks from which brine was delivered to lessees. During 1812–1834 a royalty of 12½ cents was charged to raise funds for building canals (a rebate being granted in the last three years covering the entire amount of the royalty for these years). During 1834–1846 the royalty was 6 cents, and between 1846 and 1898 it remained stationary at one cent. In 1898 the state ordered the sale of the salt lands, because the revenues were less than the expense of keeping up the works; but state ownership was maintained until 1908, when the last of the lands were sold and the office of superintendent of salt lands, created in 1797, was abolished. Until 1840 only boiled salt was manufactured; in that year the solar process was introduced. The annual production, which amounted to 100,000 bushels in 1804, reached its highest point in 1862 (9,053,874 bushels, of which 1,983,022 bushels were solar, and 7,070,852 boiled). The development of the Michigan salt deposits and (after 1880) of the deposits in Wyoming, Genesee and Livingston counties in New York caused a rapid decline in the Onondaga product. In 1876 both processes yielded together only 5,392,677 bushels, and in 1896 only 2,806,600 bushels. The salt deposits at Syracuse had, however, laid the basis for another industry, the manufacture of soda-ash, which has grown to important proportions. At the village of Solvay (pop. 1905, 5196), adjoining Syracuse on the lake shore, are the largest works for the production of soda-ash in the world, giving employment to more than 3000 hands.

The Syracuse region became known to Europeans through its salt deposits. Until several years after the close of the War of Independence, however, there was no settlement. Ephraim Webster, who built a trading-post near the mouth of Onondaga Creek in 1786, was the first white settler. About 1788–1789 small companies began to visit the place every summer to work the salt deposits. In 1796–1797 there was a permanent settlement known as Webster's Landing, and in 1797 a settlement was begun at Salina, a short distance to the north on the lake shore. Geddes, another "salt settlement," was founded in 1803. In 1800 "the landing" received the name "Bogardus's Corners," from the proprietor of a local inn. Between 1800 and 1805 a dozen families settled here, and in the latter year a grist mill, the first manufacturing establishment, was built on Onondaga Creek. A sawmill was built in the following year. In 1804 the state government, which had assumed control of the saltfields, sold to Abraham Walton of Albany, for $6550, some 250 acres, embracing the district now occupied by Syracuse's business centre, to secure money for the construction of a public road. During the succeeding years the name of the place was frequently changed. It was called Milan in 1809, South Salina in 1809–1814, Cossitt's Corners in 1814–1817, and Cossitt in 1817–1824. In 1824 a post office was established, and as there was another office of that same name in the state, the name was again changed, the present name being adopted. The village was incorporated in 1825, Salina being incorporated independently at the same time. In the meantime the settlement had been growing rapidly. In 1818 Joshua Forman bought an interest in the Walton tract, had the village platted, and became the "founder" of the city. The first newspaper, the *Onondaga Gazette*, was established in 1823; and in 1825 the completion of the Erie Canal opened a new era of prosperity. In 1827 Syracuse became the county-seat of Onondaga county. In 1847 Salina was united to Syracuse, and the city was chartered. Geddes was annexed in 1886. Syracuse has been the meeting-place of some historically important political conventions; that of 1847, in which occurred the split between the "Barnburner" and "Hunker" factions of the Democratic party, began the Free Soil movement in the state. The strong anti-slavery sentiment here manifested itself in 1851 in the famous "Jerry rescue," one of the most significant episodes following the enactment of the Fugitive Slave Law of 1850; Samuel J. May, pastor of the Unitarian church, and seventeen others, arrested for assisting in the rescue, were never brought to trial, although May and two others publicly admitted that they had taken part in the rescue, and announced that they would contest the constitutionality of the Fugitive Slave Law, if they were tried.

See Carroll E. Smith, *Pioneer Times in Onondaga County* (Syracuse, 1904).

SYR-DARYA (Gr. and Lat. *Jaxartes*; Arab. *Shash* or *Sihun*), a river of Asia, flowing into the Sea of Aral, and having a length of 1500 m. and a drainage area of about 320,000 sq. m. Its headstream is the Naryn, which rises in the heart of the Tian-shan complex south of Lake Issyk-kul, on the southern slope (12,000 ft.) of the Terskei Ala-tau. After its union with another mountain stream, the Barskaun, it flows W.S.W. at 11,000 to 10,000 ft. above the sea, in a barren longitudinal valley between the Terskei Ala-tau and the foothills of the Kokshal-tau. On entering a wild narrow gorge in the south-west continuation of the Terskei Ala-tau it receives the name of Naryn. Within this gorge it descends some 4000 ft.; Fort Narynsk, 20 m. below the confluence of the Great and the Little Naryn, is only 6800 ft. above the sea. Here the river enters a broad valley—formerly the bottom of an alpine lake—and flows past the ruins of Fort Kurtka, for 90 m. westward, as a stream some 50 yds. wide and from 3 to 11 ft. deep. Its waters are utilized by the Kirghiz for irrigating their cornfields, which contrast strangely with the barren aspect of the lofty treeless mountains. The At-bash, a large mountain stream, joins the Naryn at the head of this valley and the Alabuga or Arpa at its lower end, both from the left. Before reaching the low-lands the Naryn cuts its way through three ridges which separate the valley of Kurtka from that of Ferghana, and does so by a series of wild gorges and open valleys (170 m.), representing the bottoms of old lakes; the valleys of the Toguz-torau, 2000 ft. lower than Kurtka, and the Ketmen-tube are both cultivated by the Kirghiz. Taking a wide sweep towards the north, the river enters Ferghana—also the bottom of an immense lake—where, after receiving the Kara-darya (Black River) near Namangan, it assumes the name of Syr-darya.[1] The Kara-darya is a large stream rising on the northern spurs of the Alai Mountains. As it deflects the Naryn towards the west, the natives look upon it as the chief branch of the Syr-darya, but its volume is much smaller. At the confluence the Syr is 1440 ft. above sea-level.

The waters of the Syr-darya and its tributaries are in this part of its course largely drained away for irrigation. It is to the Syr that Ferghana is indebted for its high, if somewhat exaggerated, repute in Central Asia as a rich garden and granary; cities like Khokand, Marghilan and Namangan, and more than 800,000 inhabitants of the former khanate of Khokand, subsist by its waters. Notwithstanding this drain upon it, the Syr could be easily navigated, were it not for the Bigovat rapids at Irjar, at the lower end of the valley, where the river pierces the Mogol-tau.

On issuing from this gorge the Syr enters the Aral depression, and flows for 850 m. in a north-westerly and northerly direction before reaching the Sea of Aral. On this section it is navigated by steamers. Between the Irjar rapids and Baildyr-turgai (where it bends north) the river flows along the base of the subsidiary ranges which flank the Chotkal Mountains on the north-west, and receives from the longitudinal valleys of these alpine tracts a series of tributaries (the Angren, the Chirchik, the Keles), which in their lower courses fertilize the wide plains of loess on the right bank of the Syr.

Some 50 m. below Chinaz (770 ft. above sea-level) the Syr bends northwards, but resumes its north-westerly course 150 m. farther down, following with remarkable persistency the edge of the loess. Its low banks, overgrown with reeds and rendered uninhabitable in summer by clouds of mosquitoes, are inundated for 20 m. on both sides when the snows begin to melt. These inundations prevent the moving sands of the Kyzyl-kum desert from approaching the Syr; below Perovsk, however, the steppe does gain the upper hand. Down to Perovsk the river rolls its muddy yellow waters, at the rate of 3 to 5 m. an hour, in a channel 300 to 600 yds. wide and 3 to 5 fathoms deep; at Perovsk its vertical section is 8220 sq. ft., and 312,500 cub. ft. of water are discharged per second. The Arys and the Bugun are the only tributaries worthy of notice along this part of its course; the other streams which descend from the Kara-tau fail to reach the river. The Kirghiz rear numerous herds of cattle and

[1] *Syr* and *darya* both signify "river," in two different dialects.

sheep in the valley of the Arys, while lower down, as far as Julek, the Iginchis carry on agriculture. All this applies of course only to the right bank; on the left the moisture is absorbed by the hot winds which cross the Kyzyl-kum sands towards the river. The dryness of the atmosphere has a marked effect upon the Syr when it gets below Julek, the Kara-kum sands being then on its right. Ten miles below Perovsk the river traverses a marshy depression (the bottom of a lake not yet fully dried up), where it divides into two branches—the Jaman-darya and the Kara-uzyak. The latter spreads out into marshes and ponds, from which it again issues to join the former at Karamakchi, after a course of 80 m. The main arm, owing to its shallowness and sinuosity, is very difficult to navigate, and the difficulty is increased by the rapidity of the current and the want of fuel. Between Kazalinsk and the Sea of Aral (158 ft.) navigation becomes somewhat easier, except for the last 10 m., where the river divides into three shallow branches before entering the "Blue Sea." All three have at their mouths sandy bars with only 3 ft. of water.

Two former right-hand tributaries of the Syr—the Chu and the Sary-su—now disappear in the sands some 60 m. before reaching it. The Chu, which is 600 m. in length, rises in the Tian-shan south-west of Lake Issyk-kul, and as the Kashkar flows towards Lake Issyk-kul, but a few miles before reaching that lake turns suddenly to the north-west, enters under the name of Chu the narrow gorge of Buam, and, piercing the snow clad Kunghei Ala-tau, emerges on its northern slope, having descended from 5500 ft. to less than 2000 in a distance of not more than 50 m. In this part of its course it receives from the right the Kebin, whose high valley equals in size that of the upper Rhone. It then flows north-westwards through the valley of Pishpek, and, avoiding the Muyun-kum sands, describes a wide curve to the north before finally taking a western direction. Numberless streams flow towards it from the snow-clad Alexander Mountains, but they are for the most part lost in the sands before reaching it. The Talas, 170 m. long, formerly an affluent of the Chu, which rises in the highest parts of that range, pierces the Cha-archa Mountains, and, flowing past Aulie-ata on the south border of the Muyun-kum, enters the salt lake of Kara-kul 60 m. from the Chu. The Chu terminates in the Saumal-kul group of lakes, 60 m. from the Syr. Another elongated group of lakes—the Uzun-kul—near the above, receives the Sary-su, which has a length of nearly 570 m. and flows rapidly in a narrow channel along the western edge of the northern Famine Steppe (Bekpak-dala).

The delta of the Syr begins at Perovsk, whence it sends a branch to the south-west, the Jany-darya (New River), which formerly reached the south-eastern corner of the Sea of Aral, very near to the mouth of the Amu-darya. The Kirghiz affirm that a canal dug for irrigation by the Kara-kalpaks gave origin to this river. It had, however, but a temporary existence. A dam erected by the people of Khokand at Ak-mechet (Perovsk) caused its disappearance, and the Russians found nothing but a dry bed in 1820. When the dam was removed the Jany-darya again reappeared, but it failed to reach the Sea of Aral; in 1853 it terminated in Lake Kuchka-denghiz, after a course of 250 m.; all traces of its bed were then lost in the sand. Five centuries ago, in the time of Timur, the Mongol prince of Samarkand, the Jany-darya brought the waters of the Syr to the Daukara lakes, close by the present mouth of the Amu. The series of old river-beds in the Kyzyl-kum, which are still seen above Perovsk, indicates that the Syr had a constant tendency to seek a channel to the south-west, and that its present delta is but a vestige of what it was once. At a still more remote period this delta probably comprised all the space between the Kara-tau and the Nura-tau in Samarkand; and the series of elongated lakes at the base of the Nura-tau—the Tuz-kaneh and Bogdan-ata lakes—represent an old branch of the delta of the Syr which probably joined the Zarafshan before reaching the Amu. The cause of this immense change is simply the rapid desiccation of all the northern and central parts of Asia, due to the fact that we are now living in the later phase of the Lacustrine period, which has followed the Glacial period. The extension of the Caspian Sea as far as the Sary-kamysh lakes during the post-Pliocene period and the extension of the Sea of Aral at least 100 m. to the east of its present position are both proved by the existence of post-Pliocene marine deposits. (P. A. K.; J. T. Be.)

SYR-DARYA, or Syr-Dariinsk, a province of Russian Turkestan, lying on both sides of the Syr-darya river, from its embouchure in the Sea of Aral up to Khojent, where it issues from the mountain region of the Tian-shan. The province is bounded N. by the provinces of Turgai, Akmolinsk and Semipalatinsk; E. by Semiryechensk; S. by Ferghana, Zarafshan, Bokhara and Khiva; and W. by Khiva and the Sea of Aral. Its area (166,000 sq. m.), its population (over a million and a half) and the city of Tashkent make it the most important province of Russian Turkestan.

The south-eastern boundary runs along the Chotkal Mountains (14,000 ft.), which separate the river Chotkal from the river Naryn, and join the Alexander Mountains on the east. A series of short chains, such as the Talas-tau and Ala-tau, fringe the above on the north-west, and occupy the south-east of the province. The snow-clad summits of the Talas-tau reach 14,000 to 15,000 ft. in altitude, and immense glaciers occur about Manas Mountain. This range seems to run from west-south-west to east-north-east; the other flanking chains have a decidedly south-westerly direction, and are much lower, the outlying ranges having rather the character of broad plateaus above 2000 ft. in altitude, where the Kirghiz find excellent pasture-grounds. Some of them, such as the Kazyk-urt, rise isolated from the steppe. The Kara-tau is quite separate from the preceding and runs at right angles to them—that is, from north-west to south-east. It belongs therefore to another series of upheavals prevalent in western Asia, to which Richthofen has given the name of the "Kara-tau series." Its length is about 270 m., and its average altitude about 5000 ft., rising at some points to 6000 and 7000 ft. It separates the river Syr-darya from the river Chu, and its gentle south-western slope contains the sources of a multitude of streams which water the oasis around the town of Turkestan.

The mountainous tracts occupy, however, only a small part of Syr-darya, the rest is steppe. Three different areas must be distinguished—the Kyzyl-kum, the Muyun-kum or Ak-kum, and the Kara-kum. The Kyzyl-kum (red sands) sands stretch between the Amu and the Syr, and have a gradual ascent from 160 ft. at the Sea of Aral to 1500 and 2000 ft. in the south-east. They are partly shifting, partly stationary (see Kara-Kum). In the west the surface is overlaid with remains of Aral-Caspian deposits. As the Tian-shan is approached the steppe assumes another character: a thick sheet of loess girdles the foothills and forms the fertile soil to which Turkestan is indebted for its productive fields and gardens. The Kara-kum sands, situated north-east of the Sea of Aral, are manifestly a former bottom of the lake.

In the east the steppe yields some vegetation and is visited by the Kirghiz. The barkhans do not shift, being covered with *Calligonum*, *Tamarix*, *Holoxylon anemodendron*. The Muyun-kum or Ak-kum steppe, between the Kara-tau Mountains and the Chu River, is quite uninhabited, except in the loess region at the northern base of the mountains. (For the geological history of the western Tian-shan ranges see Tian-Shan.) Throughout the Cretaceous and earlier Tertiary periods the lowlands of Syr-darya were under the sea. The character of the region during the post-Pliocene period remains unsettled. A girdle of loess, varying in width from 30 to 50 m., encircles all the mountain tracts, increasing in extent in Bokhara and at the lower end of the valley of Ferghana. It seems certain that during the Lacustrine period the Caspian was connected by a narrow gulf with the Aral basin, which was then much larger, while another inland sea of great dimensions covered the present Balkash basin, and at an earlier period may have been connected with the Aral basin. Recent traces of these basins are found in the steppes.

The chief river of the province is the Syr-darya (*q.v.*). The frontier touches the eastern shore of the Sea of Aral, and numerous small lakes, mostly salt, are scattered over the sandy plains. A few lakes of alpine character occur in the valleys of the hilly tracts.

The climate of the province varies greatly in its different parts. It is most severe in the mountain region; and in the lowlands it is very hot and dry. As a whole, the western parts of the Tian-shan receive but little precipitation, and are therefore very poor in forests. In the lowlands the heat of the dry summer is almost insupportable, the thermometer rising to 111° F. in the shade; the winter is severe in the lower parts of the province, where the Syr remains frozen for three months. The average yearly temperature at Tashkent and Kazalinsk respectively is 58·3° and 46·4° (January, 29° and 12°; July, 77·5° and 78°).

The terraces of loess mentioned above are alone available for cultivation, and accordingly less than 1 % (0·8) of the total area of the province is under crops, the remainder being either quite barren (57 %) or pasture land (42 %). In the few cases where cultivation is possible, it is carried to great perfection owing to a highly developed system of irrigation—two crops being gathered every year. Wheat and barley come first, then peas, millet and lentils, which are grown in the autumn. Rye and oats are grown only about Kazalinsk. Cotton is cultivated. Gardening is greatly developed. Sericulture is an important source of income. Livestock breeding is largely pursued, not only by the nomads but by the settled population. Fishing is prosecuted to some extent on the lower Syr. Timber and firewood are exceedingly dear.

The population of the province was estimated in 1906 as 1,779,000. It is comparatively dense in certain parts. The Russians number barely 8500, if the military be left out of account. Kirghiz (50 %) and Sarts (9·8 %) are the main elements of the population, with Uzbegs (4·3 %), and a few Jews, Tajiks, Tatars, Persians and Hindus. The predominant occupations of the Sarts, Uzbegs, Tajiks and settled Kirghiz are agriculture and gardening, but the Kirghiz lead chiefly a nomadic pastoral life. Manufactures are represented by cotton mills, tanneries and distilleries; but a great variety of petty industries are practised in the towns and villages.

Syr-darya is divided into six districts, the chief towns of which are Tashkent, Aulie-ata, Kazalinsk, Perovsk, Chimkent and Amu-darya. (P. A. K.; J. T. Be.)

SYRIA, the name given generally to the land lying between the easternmost shore of the Levantine Gulf and a natural inland boundary formed in part by the Middle Euphrates and in part by the western edge of the *Hamād* or desert steppe. The northern limit is the Tauric system of mountains, and the southern limit the edge of the Sinaitic desert. This long strip extends, therefore, for about 400 m. between 38° and 31° N. lat. with a mean breadth of about 150 m. Since, however, the steppe edge on the east is somewhat indefinite, some early Moslem and other geographers have included all the Hamād in Syria, making of the latter a blunt-headed triangle with a base some 700 m. long resting on the north Arabian Nefud. But Strabo, Pliny and Ptolemy, as well as the better Moslem geographers, drew the eastern frontier obliquely from the Gulf of Akeba to Rakka (Raqqa) on Euphrates, and thus placed the Hamād in Arabia.

The name *Syria* is not found in the Hebrew original of the Scriptures; but it was used by the Septuagint to translate Aram. Homer knows only Ἄριμοι, but Herodotus speaks of "Syrians" as identical with Assyrians, the latter being, he thinks, a "barbarian" form, and he applies the name very widely to include, *e.g.* north Cappadocians ("White Syrians" of Pteria). Syria, however, is probably the Babylonian *Suri*, used of a north Euphratean district, and a word distinct from Assyria. Generally the ethnic term, Syrians, came to mean in antiquity the Semiti peoples domiciled outside the Mesopotamian and Arabian areas: but neither in pre-Greek nor in Greek times had the word Syria any very precise geographical significance, various lands, which we include under it, retaining their distinctive status, *e.g.* Commagene (Kummukh), Cyrrhestica, Phoenicia, Palestine, &c. It is only under the Graeco-Roman administration that we find a definite district known as Syria, and that was at first restricted to the Orontes basin. Later, all that we understand by Syria came to be so known officially to the Romans and Byzantines; but the only province called simply Syria, without qualification, remained in the Orontes valley. Under the present Ottoman distribution "Syria" is the province of Sham or Damascus, exclusive of the vilayets of Aleppo and Beirut and the sanjaks of Lebanon and Jerusalem, which all fall in what is called Syria is the wider geographical sense.

Taking Syria as the strip limited by the sea, the edge of the Hamād, the Taurus and the Sinaitic desert, we have a remarkably homogeneous geographical area with very obvious natural boundaries; but these, for various reasons, have proved very ineffective in history, especially on the south and east. Syria happens to lie on the line of least resistance for communication between the early subtropic seats of civilization in the Nile and Euphrates valleys and the civilizations of Europe. Its eastern boundary is in great part a steppe, which breeds population, but, unable to nourish increase, sends it over its boundaries in a constant stream of migration. Consequently south Palestine has been continuously "Arabized"; and indeed the whole of Syria has been characterized by racial and religious fusions, and by civilization of a singularly syncretic and derived kind, of which the ancient Phoenician is a sufficient example.

The surface configuration of almost all the strip is remarkably uniform. With the exception of the extreme north (Commagene), which is shut off by a barrier of hills and belongs to foreign hydrographic systems, the whole country is roughly a gable-shaped plateau, falling north and south from a medial ridge, which crosses Syria at about its central point. This gable is tilted eastwards, and its two long slopes are defined by bordering mountain chains which run across its medial ridge; the main Syrian streams are those which follow those slopes between the chains, thus running either north or south for most of their courses, and only finding their way to the western sea by making sharp elbows at the last. Syrian orography, therefore, is simple, being composed of nothing but these two parallel systems. That on the west, which rises behind the Mediterranean littoral, springs from Taurus in the well-afforested Mt Amanus (Giaour Dagh), and is continued by Jebel Bereket and J. Akhma, over the northern end of which runs a single easy pass (Beilan) to the north-east angle of the Levant coast (Alexandretta), while at the southern end is a gap through which the Orontes turns sharply to the sea. South of this, with J. Akra (the Bald Mountain, anc. *Casius*) begins a further section, rounded and grassy, called J. Ansariya, which presently springs up into a high chain of Jurassic limestone with basaltic intrusions, whose peaks rise to 10,000 ft. and whose passes do not fall under 6000 ft. Here it is called J. al-Gharbi or Libnan (see LEBANON). Thereafter it broadens out and becomes the high table-land of Galilee, Samaria and Judaea, and gradually sinks into the plateau of north Sinai.

The eastern system springs from the Tauric offshoot (Kurd Dagh, &c.), which shuts off the Commagenian basins, and as the triple chain of J. al Ala, it defines the Orontes valley on the east. Like its western parallel it springs up presently into a higher chain and is known as J. es-Sharki, or Anti-Libanus, which culminates in a knot on the south, to which is given the name J. es-Sheikh, or Hermon (8000 ft.). Thereafter it loses much of its distinctive character, but may be traced southwards in J. Ḥauran and the Moabite hills to Horeb and the Midianite Mountains of the Hebrews, which run into Arabia.

Hydrography.—Between these systems run the main rivers; and these naturally rise near the medial ridge, in the lacustrine district of el-Buka'a, or Coelesyria, and flow in opposite directions. That following the northern slope is the Nahr al-'Asi (see ORONTES) into which, when it has turned sharply towards the sea, flow some tributary streams from the Commagenian divide on the north. The main stream flowing south is the Jordan, which fails to reach the sea, being absorbed into the great rift of the Ghor: but a smaller stream, the North Litani (called Kasimiya in its lower course), whose source lies very near that of Jordan, repeats the course of the Orontes on a minor scale and gets through the western mountain system to the sea near Sur (Tyre). Outside the basins of these rivers and their bordering mountain systems there only remain to be considered the following: (1) The Mediterranean littoral strip (the ancient PHOENICIA), with a few torrent-like streams. (2) The shut-off district in the extreme north, ancient Commagene, which consists of two basins divided by a low ridge running from south to north. These basins belong, one to the Cilician river-system, and the other to the Euphratean. In the first lay the ancient Germanicia (mod. Marash); in the second the ancient Samosata (mod. Samsat), whose importance has now passed to Adiaman. The southern boundary of both basins is a low chain which leaves the Euphrates near the mouth of the Sajur tributary, and runs west towards Mt Amanus, to which it is linked by a sill whereon stood the ancient fortified palace of Samal (Sinjerli; see HITTITES). (3) A succession of oases lying east of the eastern mountain system on the edge of the steppe, and fed by short local streams. Of these the most important are, from north to south, (*a*) the Saltpan of Jebeil, fed by the North al-Dahab; (*b*) the oases of Kinnesrin and Aleppo, fed by the North Kuwaik; and (*c*) that of Sham or Damascus, fed by streams from Hermon, of which the Barada (Abana) and the Awaj (Pharpar) are the chief.

Since these streams had in no case originally easy access to the sea, we naturally find lakes on their course, and several of them terminate in tracts of more or less permanent inundation. Those which occur on the course of the principal rivers are described under ORONTES and JORDAN. The others, which terminate streams, are the Bahr el-Ateiba, which receives the waters of Damascus; the Mat, into which the Kuwaik flows below Kinnesrin; and the Ak Deniz, or Bahrat Antakia, the ancient Lake of Antioch, which collects the waters of the Kara Su and Afrin, the southward from the watershed which shuts off Commagene. The last-named lake has now been almost entirely dried up by the cutting of a channel, which conducts its feeders directly to the Orontes.

Geology.—Geologically, Syria belongs to two distinct regions of the earth's crust, the northern and smaller portion lying within the great belt of folding of southern Europe and central Asia, and the southern and larger portion belonging to the Indo-African area, which, though often faulted, is usually free from crumpling. According to M. Blanckenhorn the boundary between the two regions runs from the Bay of Jebele along the Afrin River to Aintab, and thence to the Euphrates above Birejik. In the southern region which is by far the better known, the oldest rocks are granites, crystalline schists and other rocks of Archean aspect. These are overlaid by conglomerates, tuffs, sandstones and arkoses, which perhaps do not all belong to the same period. In Palestine a limestone containing Carboniferous fossils is found in the midst of the sandstone series, and here the sandstone is immediately succeeded by limestones with Hippurites and other fossils belonging to the Upper Cretaceous. Farther north, however, Jurassic beds are met with, but of very limited extent. Cretaceous limestones cover the greater part of Palestine and rocks of the same period form Mt Lebanon, the Casius Mons, &c., farther north. Nummulitic limestone (Eocene) overlies the Cretaceous in Philistia, and north of Lebanon Eocene and Miocene deposits cover the greater part of the country. The Pliocene deposits are not very widely spread and are generally of fresh-water origin excepting near the coast, but marine Pliocene beds have been found at el Forklus in the Palmyra desert. Jebel Hauran, east of the Jordan, is capped by a great sheet of basalt; and many other basalt flows are found, especially in the country north of Lebanon. They are mostly true felspar basalts, but a few contain nepheline in addition to the felspar. In most cases the eruptions appear to be of Pliocene or later date, but in the extreme north some of the basalt seems to belong to the Miocene period. There is historic evidence of mud eruptions in some of the volcanic areas. The most striking feature in the structure of Syria is the existence of long *Graben*, or narrow depressions formed by faulting. The best known of these Graben is that of the Jordan, but the upper part of the Orontes lies in a similar depression, which is, indeed, very probably the continuation of the Jordan-Araba trough. The faulting which formed the depressions is certainly later than the deposition of the Cretaceous beds and probably belongs to the later portion of the Tertiary era. Little is known of the part of Syria which lies within the folded belt, and includes the Amanus and Kurd mountains. The rocks do not appear to differ very markedly from those farther south, but the Devonian is believed to be represented. The folds are approximately parallel to those of the Taurus, and geologically these mountains may be said to belong to that range.[1]

Climate.—Within historic times the climate, and with it the productivity of the country, cannot have greatly changed; at most the precipitation may have been greater, the area under wood having been more extensive. Except for Jerusalem, we have hardly any accurate meteorological observations; there the mean annual temperature is about 63° F.; in Beirut it is about 68°. The rainfall in Jerusalem is 36·22 in., in Beirut 21·66. The heat at Damascus and Aleppo is great, the cooling winds being kept off by the mountains. Frost and snow are occasionally experienced among the mountains and on the inland plateaus, but never along the coast. Even the steppe exhibits great contrasts of temperature; there the rainfall is slight and the air exceedingly exhilarating and healthy. The sky is continuously cloudless from the beginning of May till about the end of October; during the summer months the nights as a rule are dewy, except in the desert. Rain is brought by the west wind; the north-west wind, which blows often, moderates the heat. On the other hand, an ozoneless east wind (sirocco) is occasionally experienced—especially during the second half of May and before the beginning of the rainy season—which has a prejudicial influence on both animal and vegetable life. On the whole the climate of Syria—if the Jordan valley and the moister districts are excepted—is not unhealthy, though intermittent fevers are not uncommon in some places.

The general character of the country, resultant on these conditions, varies according to elevation and latitude. Owing to the high barrier which shuts off almost all Syria from the sea, and precipitates vapours mainly on the western slope, little of the land is highly productive without irrigation, except the narrow littoral strip which was the ancient Phoenicia, and the small deltas, such as that of Latakia (Laodicea). Palestine, being less shut in and enjoying a comparatively large general rainfall, would be still a land "flowing with milk and honey" had its forests not been destroyed, and the terracing, which used to hold up soil on the highlands, been maintained. As it is, it has very fertile patches of lowland, such as the plains of Esdraelon and Jaffa; and the high levels, largely composed of disintegrated igneous rock, west of Jordan, over which the sea-wind carries the rains, offer excellent corn-land. In the extreme south Palestine begins to be affected by the Arabian dryness. For the rest, Syria needs irrigation; and since neither of its larger rivers, Orontes or Jordan, flowing as these do in deep beds, is of much use for this purpose, all Mid-Syria, except the lacustrine oases, is a region mainly occupied by pastures, and yielding only thin cereal crops. Commagene, where not rocky, and the district lying along the southward drains from its divide (anc. *Cyrrhestica*), is in better case, enjoying perennial streams which can be utilized, and the fringe of the Tauric rainfall. The latter dies away over the plains east and south-east of Aleppo, making them afford good spring pasture, which has attracted the nomads from farther south: but below the latitude of Rakka-Homs thin steppe begins, and quickly degenerates into sheer desert broken only by a chain of poor oases, south of a low ridge running from Anti-Lebanon to Euphrates. Of these the principal are Karietein and Tadmor (Palmyra), through which passes the trade from Damascus to the east. In ancient times,

[1] See O. Fraas, *Aus dem Orient*, pt. ii. (Stuttgart, 1878); C. Diener, *Libanon* (Vienna, 1886); M. Blanckenhorn, *Beiträge zur Geologie Syriens* (Cassel, 1890, &c.), and *Grundzüge der Geologie und physikalischen Geographie von Nord-Syrien* (Berlin, 1891). See also the references under PALESTINE. A summary by M. Blanckenhorn will be found in *Monatsschr. f. wirtschaftl. Erschliessung Palästinas*, pp. 289–301 (Berlin, 1904).

up to the Arab invasion, the northern part of the eastern plateau, between Orontes and Euphrates, was made habitable and even fertile by storage of rainfall. It supported a large number of villages and small towns, whose remains are remarkably well preserved, and still serve to shelter a sparse pastoral population.

Flora.—Two distinct floral regions meet in Syria, that of the Mediterranean and that of the west Asian steppe-land. The first, to be seen on the coast and the western slopes of the highlands, is characterized by a number of evergreen shrubs with small leathery leaves, and by quickly-flowering spring plants. On the lowest levels the southern forms, the *Ficus sycomorus* and the date-palm, appear, and increase in the direction of Egypt (see LEBANON and PALESTINE). The steppe region, whose flora begins to appear east of the western ridge, is distinguished by the variety of its species, the dry and thorny character of its shrubs, and great poverty in trees. Between these regions the greatly depressed valley of Jordan shows a subtropic vegetation. Among cultivated trees, the olive is at home throughout Syria, except on the steppe; the mulberry is planted extensively in the lower Lebanon; and all sorts of fruit-trees flourish in irrigated gardens, especially on the Phoenician coast, in the Palestinian plain, in the oasis of Damascus, and in the Buka'a, The main cereal regions are the Hauran, and the plains of Antioch and Commagene; and the lower western slopes of the coast range are largely devoted to the culture of tobacco. On the northern inland downs liquorice grows wild and is collected by the peasants and sent down to Alexandretta.

Fauna.—The mammals of Syria are rather sharply to be distinguished into those which range only north of Mt Carmel, and those which pass that limit. The first class includes the isabelline bear, badger, pole-cat, ermine, roe and fallow deer, wild ass, Syrian squirrel, pouched marmoset, gerbill and leopard. The second class will be found under PALESTINE; and it includes a sub-class which is not found outside Palestine at all. In the latter are the coney, jerboa, several small rodents and the ibex. Only in the Jordan valley do intrusions from the Ethiopic region appear. Elsewhere the forms are Palaearctic with intrusions from the east; but the length of the Syrian strip and the variety of its surface relief admit of considerable difference in the species inhabiting different districts. The Lebanon and the hills of north Galilee offer the greatest number of mammals.

Population.—The actual population of Syria is over 3,000,000, spread over a superficial area of about 600,000 sq. m., *i.e.* about 5½ persons to the square mile. But this poor average is largely accounted for by the inclusion of the almost uninhabited northern steppe-land; and those parts of Syria, which are settled, show a much higher rate. Phoenicia and the Lebanon have the densest population, over 70 to the square mile, while Palestine, the north part of the western plateau east of Jordan, the oases of Damascus and Aleppo, the Orontes valley, and parts of Commagene, are well peopled. The bulk of the population, so far as race goes, is of the Semitic family, and at bottom Aramaean with a large admixture of immigrant Arabian blood, which is constantly being reinforced, and a comparatively small strain of Hebrew blood. The latter appears mainly in Palestine, and has of late been considerably strengthened by immigration of European Jews, who have almost doubled the population of Jerusalem, and settled upon several fertile spots throughout the Holy Land. But how far these, or the indigenous " Jews " are of Hebrew rather than of Aramaean origin is impossible to say. We only know that as long ago as the 1st century B.C. true Hebrew blood was becoming rare, and that a vast proportion of the Jews of Roman times were Hebraized Aramaeans, whose assimilation into the Jewish community did not date much further back than the Maccabaean age.

Among this Semitic folk is to be observed a great variety of immigrant stocks, settled in isolated patches, which have done much to contaminate the masses about them. In the extreme north (Commagene) the highlands are almost entirely held by Kurds who entered from beyond Euphrates in comparatively recent times. Kurds live upon the Commagenian plains here and there, as also in the northern trans-Euphratean plains. Among them in the Tauras and Amanus, and outnumbering them on the plains, are Armenian communities, the remains of the Rupenian invasion of the 10th century A.D. (see ZEITUN). These are found as far south as the plain of Antioch and the basin of the Sajur. To the north of Aleppo and Antioch live remnants of pre-Aramaean stocks, mixed with many half-settled and settled Turkomans (Yuruks, Avshars, &c.) who came in before the Mahommedan era, and here and there colonies of recently imported Circassians. The latter are also settled numerously to the west of Jordan. Mid-Syria shows a medley of populations of more or less mixed origin, in large part alien, for which see DRUSES; MARONITES and LEBANON. In the Phoenician coast towns are many Greeks (to be distinguished from Orthodox Syrians, called also Greeks on account of creed). In the steppe-land and in the southern trans-Jordanic districts are numbers of true Arabs, mostly belonging to the great Anazeh family, which has been coming northwards from Nejd in detachments since the 13th century. These are mainly nomadic, and include offshoots of the great tribes of Ruala, Walad Ali, B. Sokhr, Adwan and Bishr, the first two roaming mainly in the north, the last two in Moab and Ammon. Ottoman Turks, scattered gipsy communities, German settlers in north Palestine, and all sorts of Europeans make up a heterogeneous and incompatible population.

Religion.—The religious types also are strongly divergent. The bulk of the population is Mahommedan; the Bedouins have not much religion of any kind, but they profess Islam. Besides orthodox Moslems there are also Shi'ite sects, as well as a number of religious communities whose doctrine is the outcome of the process of fermentation that characterized the first centuries of Islam. To this last class belong the Ismailites (Assassins), *q.v.*, Metawali, Nosairis, Ansarieh, and especially the Druses (*q.v.*). In many cases it is obvious that the political antipathy of the natives to the Arabs has found expression in the formation of such sects. The Ansarieh, for instance, and no doubt the Druses also, were originally survivals of the Syrian population. The Jews are found mainly in the larger centres of population. The Christians are an important element, constituting probably as much as a fifth of the whole population; the majority of them belong to the Orthodox Greek Church, which has two patriarchs in Syria, at Antioch and Jerusalem. Catholics—United Greeks, United Syrians and Maronites—are numerous. The mission of the American Presbyterian Church, which has had its centre in Beirut for the last sixty years, has done much for Syria, especially in the spread of popular education; numerous publications issue from its press, and its medical school has been extremely beneficial. The Catholic mission has done very good work in what relates to schools, institutes and the diffusion of literature. The Christians constitute the educated portion of the Syrian people; but the spirit of rivalry has produced stimulative effects on the Mahommedans, who had greatly fallen away from that zeal for knowledge which characterized the earlier centuries of their faith.

Language.—The language throughout southern and middle Syria as high as Killis is Arabic, which has entirely ousted Aramaic and Hebrew from common use, and tends to prevail even over the speech of recent immigrants like the Circassians. The last survivals of Aramaic are to be sought in certain remote villages of Anti-Lebanon, and in the Syriac known to the clergy. From the upper Sajur northwards Turkish prevails, even among the Armenians; but many Kurdish communities retain their own tongue.

Government.—The political status of the country is controlled by the Ottoman Empire, of which Syria makes part, divided into the vilayets of Aleppo, Sham or Syria (Damascus), the Lebanon (*q.v.*) and Beirut, and the separate sanjaks or mutessarifliks of Zor and Jerusalem. Ottoman control is imperfect in Lebanon, the Houran, and over the Armenian mountain region of Zeitun and over the eastern steppe-lands, whose nomadic populations can withdraw themselves out of reach. But considerable success has been achieved in inducing the Syrian Arabs to settle and in supplying a counteracting influence to their unrest by the establishment of agricultural colonies, *e.g.* those of the Circassians in Bashan, Ammon and Moab.

Communications are still very imperfect, but have been greatly improved of late years. Railways run from Beirut to Homs, Hamah, Aleppo and Damascus (French), and to the latter also from Haifa (Turkish). From the termination of the Damascus-Mzerib railway a line (the " Mecca railway ") has been laid by Ottoman enterprise east of Jordan to the southern limit of Syria and beyond. From Jaffa a short line runs to Jerusalem, and a steam tramway connects Beirut with Tripoli. There are carriage roads radiating from Aleppo to the sea at Alexandretta, and to Aintab; and Antioch is also connected with Alexandretta; Beirut and Homs with Tripoli; Damascus with Beirut; and Nazareth with Haifa. But carriage roads in the Ottoman dominions are seldom completely made, and hardly ever kept in repair. The Lebanon district is well supplied with both roads and made mule-tracks.

Commerce.—From the Egyptian and Assyrio-Babylonian monuments we learn that in ancient times one of the principal exports of Syria was timber; this has now entirely ceased. But it continues to export wheat. Other articles of export are silk cocoons, wool, hides, sponges, eggs and fruits (oranges, almonds, raisins and the like); the amounts of cotton, tobacco and wine sent out of the country are small. The only good harbours are those of Beirut and Alexandretta (Iskanderun). The caravan trade with the East has almost entirely ceased, and the great trade routes from Damascus northwards to Aleppo and eastwards through the wilderness are quite abandoned. The traffic with Arabia has ceased to be important, being limited to the time of the going and returning of the great pilgrimage to Mecca, which continues to have its mustering-place at Damascus, but leaves mainly by rail. The native industries in silk, cotton and wool have been almost entirely destroyed by the import trade from Europe. The land is poor in minerals, including coal; water-power also is deficient, so that the introduction of European industries is attended with difficulties even apart from the insecurity of affairs, which forbids such experiments as the improvement of agriculture by means of European capital. As regards the cultivation of the soil Syria remains stable; but the soil is becoming relatively poorer, the value of the imports constantly gaining upon that of the exports. The latter are estimated at some 2½ millions sterling; the former at 4 millions.

History.—Rude stone monuments (circles and dolmens) and other prehistoric remains show that Syria must have been inhabited from a very early period. Within historic times a great number of different nationalities have fought and settled within its borders, the majority belonging to the Semitic stock. This last circumstance has rendered possible a considerable degree of fidelity in the tradition of the oldest local names. After the Aramaeans had absorbed what remained of the earlier population, they themselves were very powerfully influenced by Graeco-Roman civilization, but as a people they still retained their Aramaean speech. Of the political relations of Syria in the most ancient times we know but little. Each town with its surrounding district seems to have constituted a small separate state; the conduct of affairs naturally devolved upon the noble families. In the latter part of the 16th century B.C. all north Syria fell under the Cappadocian Hatti domination. The south part of Syria was known to Sargon of Akkad (*Agade*) as Ammon and was visited by his armies. This is known as the Canaanite period, succeeded about 1000 B.C. by the Aramaean. At a very early period—as early probably as the 16th century B.C.—Syria became the meeting-place of Egyptian and Babylonian elements, resulting in a type of western Asiatic culture peculiar to itself, which through the commerce of the Phoenicians was carried to the western lands of the Mediterranean basin. Industry especially attained a high state of development; rich garments were embroidered, and glass, pastes, faience, &c., were manufactured. The extant inventories of spoil carried off by the ancient conquerors include a variety of utensils and stuffs. The influence exercised at all times on Syrian art by the powerful neighbouring states is abundantly confirmed by all the recent finds which, in addition to our previous knowledge, show the action of the Aegean culture on Phoenicia and Palestine. The Syrians were more original in what related to religion; every place, every tribe, had its "lord" (Ba'al) and its "lady" (Ba'alat); the latter is generally called 'Ashtar or 'Ashtaret (*i.e.* Ishtar, Astarte). Besides the local Baal there were "the god of heaven" (El) and other deities; human sacrifices as a means of propitiating the divine wrath were not uncommon. But in the Syrian mythology foreign influences frequently betray themselves. Over against its want of originality must be set the fact, not merely that Syrian culture ultimately spread extensively towards the West, but that the Syrians (as is shown by the inscriptions of Teima, &c.) long before the Christian era exercised over the northern Arabs a perceptible influence which afterwards, about the beginning of the 1st century, became much stronger through the kingdom of the Nabataeans. The art of writing was derived by the Arabs from the Syrians.

Something about the ancient political and geographical relations of Syria can be gleaned from Egyptian sources, especially in connexion with the campaigns of Tethmosis (Thothmes) III. in western Asia and the administration of Amenophis (Amenhotep) IV. (the Tell el-Amarna Letters). The Egyptians designated their eastern neighbours collectively as 'Amu. Syria up to and beyond the Euphrates is called more precisely Ṣahi (or Zahi), and is regarded as consisting of the following parts: (1) Rutenu, practically the same as Palestine (occasionally Palestine with Coelesyria is called Upper Rutenu, as distinguished from Lower Rutenu extending to the Euphrates); (2) the land of the Kheta (sometimes reckoned as belonging to Rutenu with Kadesh on the Orontes as its capital in the Ramesside period; (3) Naharina, the land on both sides of the Euphrates (extending, strictly speaking, beyond the Syrian limits). The Canaanites in general are called Kharu. From these lands the Egyptian kings often derived rich booty, so that in those days Syria must have been civilized and prosperous. Moreover, we possess enumerations of towns in the geographical lists of the temple of Karnak and in a hieratic papyrus dating about 200 years after Tethmosis III. Some of these names can be readily identified, such as Aleppo, Kadesh, Sidon, and the like, as well as many in Palestine. The Tell el-Amarna Letters (15th century B.C.) show Syria held in part by Egyptian viceroys, who are much preoccupied with southward movements in the Buka'a and the rest of the interior beyond their control, due to pressure of Amorite peoples, and of the Mitanni and the Kheta, whose non-Semitic blood was mingled with that of the Aramaeans even in Palestine. On the latter in Syria, see HITTITES. It need only be said here that this people bulked most largely in the relations of Egypt with Syria from the 16th to the 14th centuries. During the reign of Rameses II. it was centred on the upper Orontes (Kadesh) and had comparatively free access to Palestine and the Egyptian border. Later on we find Kheta focused farther north, on the middle Euphrates (Carchemish), and more or less cut off from Egypt by the Hebrew state. They or their confederacy remained, however, the most powerful of the Syrian elements till the westward extension of Assyria about 1050 B.C., under Tiglath-Pileser I. Late in the 8th century Sargon III. took Carchemish and ended Hittite power.

With the fall of the Kheta the Aramaeans were the people who held the most important towns of Syria, gradually advancing until at last they occupied the whole country. Of the Aramaean stocks named in Gen. x. 23, xxii. 21 seq., very little is known, but it is certain that Aramaeans at an early period had their abode close on the northern border of Palestine (in Maachah). A great part was played in the history of Israel by the state of Aram Dammesek, *i.e.* the territory of the ancient city of Damascus; it was brought into subjection for a short time under David. The main object of the century-long dispute between the two kingdoms was the possession of the land to the east of the Jordan (Ḥauran, and especially Gilead). Another Aramaean state often mentioned in the Bible is that of Aram Zobah. That Zobah was situated within Syria is certain, though how far to the west or north of Damascus is not known; in any case it was not far from Ḥamath (Ḥamah). Ḥamath in the valley of the Orontes, at the mouth of the Buka'a valley, was from an early period one of the most important places in Syria; according to the Bible, its original inhabitants were Canaanites. The district belonging to it, including amongst other places Riblah (of importance on account of its situation), was not very extensive. In 733 B.C. Tiglath-Pileser II. compassed the overthrow of the kingdom of Damascus; he also took Arpad (Tel Arfad), an important place three hours to the north of Aleppo. Ḥamath was taken by Sargon in 720. Henceforward the petty states of Syria were at all times subject to one or other of the great world-empires, and were still in dispute between Babylonia and Egypt as late as Necho. Thereafter the Mesopotamian powers prevailed, even if in some cases a certain degree of independence was preserved, as *e.g.* by the Phoenician cities. These, however, in spite of more than one revolt, continued to supply fleets to the Persians down to the time of the Macedonia invasion (332 B.C.), and inland Syria remained comparatively peaceful first under its own local governors, and, after Darius, as a satrapy, till its subjugation by Alexander. Alien domination alone has been able to correct the tendency of this long strip of land to break up into hostile belts.

The foundation of numerous Greek cities shortly after Alexander's time was of great importance for Syria (see *e.g.* ANTIOCH). The Graeco-Syrian civilization extended far to the south down both sides of Jordan, and, but for the Maccabaean revival, would have absorbed the Jews. The Seleucidae had severe struggles with the Ptolemies for the possession of the southern part of Syria.

After having been reckoned for a short time (from 83 to 69 B.C.) among the dominions of Tigranes, king of Armenia, the country was conquered for the Romans by Pompey (64–63 B.C.). It is impossible here to follow in detail the numerous changes in the distribution of the territory and the gradual disappearance of particular dynasties which maintained a footing for some time longer in Chalcis, Abila, Emesa and Palestine; but it is of special interest to note that the kingdom of the Arab Nabataeans was able to keep its hold for a considerable period on the north as far as Damascus. In the year 40 B.C. Syria had to endure a sudden but brief invasion by the Parthians. The country soon became one of the most important provinces of the Roman Empire; its proconsulship was from the first regarded as the most desirable, and this eminence became still more marked afterwards. Antioch, adorned with many sumptuous buildings, as the chief town of the provinces of Asia, became in point of size the third city of the empire and an eastern Rome. The high degree of civilization then prevailing in the country is proved by its architectural remains dating from the early Christian centuries; the investigations of De Vogüé, Butler and others, have shown that from the 1st to the 7th century there prevailed in north Syria and the Ḥauran a special style of architecture —partly, no doubt, following Graeco-Roman models, but also showing a great deal of originality in details.

The administrative divisions of Syria during the Roman period varied greatly at different times. Hadrian made three provinces of it, Syria, Syria Phoenice and Syria Palestina. At the beginning of the 5th century we find the following: (1) Syria Euphratensis, which had for its capital Hierapolis (*q.v.*). (2) Syria I., or Coelesyria, having Antioch as its capital. The name Coelesyria (ἡ κοιλὴ Συρία), no doubt, was applied originally to the valley ("hollow") between Lebanon and Anti-Lebanon, but was afterwards extended to the district stretching eastwards from the latter range. (3) Syria II., or Syria Salutaris, with Apamea as capital. (4) Phoenice Maritima; capital, Tyre. (5) Phoenice ad Libanum; capital, Emesa (Homs). To this division Damascus and Palmyra belonged; occasionally they were reckoned to Coelesyria, the middle strip of coast being designated Syrophoenicia. (6, 7, 8) Palestina I., II. and III. (9) Arabia (capital, Bostra), which embraced all the region from the Ḥauran to the Arnon, and skirted the Jordan valley, stretching southwards to Petrae. Through the kingdom of the Nabataeans Roman influence penetrated from Syria far into northern Arabia.

In 616 Syria was subjugated for a brief period by the Persian Choroes II.; from 622 till 628 it was again Byzantine; 636 and the immediately following years saw its conquest by the Mahommedans (see CALIPHATE). Moawiya, the first Omayyad caliph, chose Damascus for his residence; but in 750 the capital of the empire was removed by the Abbasids to Bagdad. Under the early caliphs the Arabs divided Syria into the following military districts (*gonds*). (1) Filistin (Palestine), consisting of Judaea, Samaria and a portion of the territory east of Jordan; its capital was Ramleh, Jerusalem ranking next. (2) Urdun (Jordan), of which the capital was Tabaria (Tiberias); roughly speaking, it consisted of the rest of Palestine as far as Tyre. (3) Damascus, a district which included Baalbek, Tripoli and Beirut, and also the Ḥauran. (4) Ḥoms, including Ḥamath. (5) Kinnesrin, corresponding to northern Syria; the capital at first was Kinnesrin (Qinnasrin) to the south of Ḥaleb (Aleppo), by which it was afterwards superseded. (6) The sixth district was the military frontier (*'awāsim*) bordering upon the Byzantine dominions in Asia Minor. During the struggles of the Mahommedan dynasties for the possession of Syria the country still enjoyed a considerable degree of prosperity.

In the crusading period the kingdom of Jerusalem, whose rulers were never able to establish a foothold to the east of the Jordan, extended northwards to Beirut; next to it lay the countship of Tripoli on the coast; and beyond that in north Syria was the principality of Antioch. Syria suffered severely from the Mongol invasions (1260), and it never recovered its former prosperity. In 1516 the Ottomans took it from the Egyptian Mamelukes. For its subsequent history, see TURKEY: *History*. Its medieval importance as an intermediary of trade between Europe and the East was greatly impaired by the opening of the Red Sea route, and finally abolished by the Suez Canal; and Syria is at present important mainly for the sentimental reason that it contains the holiest places of Judaism and Christianity, and for the strategic reason that it lies on the flank of the greatest trade-route of the eastern hemisphere.

SYRIAC LANGUAGE. Syriac is the eastern dialect of the Aramaic language which, during the early centuries of the Christian era, prevailed in Mesopotamia and the adjoining regions. Its main centres were at Edessa and Nisibis, but it was the literary language of practically all the Christian writers in the region east of Antioch, as well as of the Christian subjects of the Persian empire.

All the Semitic languages[1] are built up from triliteral roots: that is, the great majority of the words are derived from a simple verbal form, of which the essential elements are three consonants. This form is seen in the 3rd pers. sing. perf. of the verb, *e.g.* Aram. *q'ṭal* or *ḳ'ṭal* (" he killed "), which corresponds to Heb. *qāṭal* and Arab. *qatala*. The vowels play no part in differentiating the roots, for the vowels are practically the same in the corresponding forms of every root. The form *q'ṭal* illustrates one main peculiarity of Aramaic, as opposed to the other Semitic languages, viz. its paucity of vowels: for where Hebrew has two full vowels—a long and a short— in *qāṭal*, and Arabic has three short vowels in *qatala*, Aramaic has only one short vowel, the sound ' between *q* and *ṭ* being merely a half vowel which is not indicated in Syriac writing. Another chief characteristic of Aramaic appears in nouns, viz. the entire absence of a prefixed definite article. Aramaic gives to the noun instead an ending *ā*,

[1] On the place of Aramaic among the Semitic languages, and of Syriac among the various dialects, see SEMITIC LANGUAGES.

making the so-called "emphatic" state. In the older Aramaic dialects this is used exactly as the noun with prefixed article is used in other languages; but in Syriac the emphatic state has lost this special function of making the noun definite, and has become simply the normal state of the noun. The main grammatical distinction between Syriac and all the west Aramaic dialects is that in Syriac the 3rd person of the imperfect (singular and plural) of the verb begins with *n*, but in west Aramaic, as in the other Semitic languages, it begins with *y*.

When, in the 5th century A.D., owing to theological differences the Syriac-using Christians became divided into Nestorians or East Syrians and Jacobites (Monophysites) or West Syrians, certain differences of pronunciation, chiefly in the vowels, began to develop themselves. The East Syrians in most cases kept the more primitive pronunciation: *e.g.* the old Semitic *ā* with them remained *ā*, but with the Jacobites passed into *ō*. One very tangible difference appears in the fact that the name *Jesus* was by the East Syrians written and pronounced *Īshō'*, by the West Syrians *Yeshū*.

The Syriac alphabet, which derived its letters from forms ultimately akin to those of the Old Hebrew and Phoenician alphabets, has the same twenty-two letters as the Hebrew. And as in Hebrew, the six letters *b g d k p t* are aspirated when immediately preceded by any vowel sound. On the other hand, the guttural letters affect the vowels much less than in Hebrew: their chief effect is when final to change the preceding vowel, if other than *a* or *ā*, into *a*, but even this is not always the case.[1] The vowels, which are ten in number (ā a ē e ī i ō o ū u), were, as usual in the Semitic languages, indicated only partially by the use of consonants as vowel-letters[2] and by means of certain diacritical points, so long as Syriac remained a living language. But about the time when it began to be supplanted by Arabic, two systems of vowel-signs were invented, one for the West Syrians, who borrowed the forms of Greek vowels, and the other more elaborate for the East Syrians, who used combinations of dots. Neither system completely differentiates long and short vowels; the Nestorian scheme is the more satisfactory, though more cumbrous.

Where the same root exists in Arabic, Syriac and Hebrew, its fundamental consonants are usually the same in all three languages. But letters belonging to the same group occasionally interchange. As regards the dentals and sibilants there are one or two rules which govern the interchange, in the manner of a Grimm's Law. (1) Where Arabic has an ordinary dental, Syriac and Hebrew have the same; but where Arabic has an aspirated dental (*e.g. th*), Syriac has an ordinary dental *t*, but Hebrew has a sibilant (*sh*). (2) Hebrew has one more sibilant than Arabic or Syriac: thus, as corresponding to *s* (*sāmekh*), *s* (*sīn*) *sh* in Hebrew, Arabic has only *s* (*sīn*) *sh*, while Syriac has a different pair *s* (*sāmekh*) *sh*. Hebrew *sāmekh* is represented by Ar. *sīn* and Syr. *sāmekh*; but Heb. *sīn* (Syr. *sāmekh*) is represented by Ar. *sh*, while Heb. and Syr. *sh* is represented by Ar. *sīn*. As regards this crossing of *s* and *sh*, Arabic has with it the other south Semitic language, Ethiopic: the evidence as to the other north Semitic language, Assyrian, is conflicting.

In vowel-sounds Syriac is clearly more primitive than Hebrew (as pointed by the Massoretes), less so than Arabic. Thus Ar. and Syr. *a* is often thinned in Hebrew into *i* (*ē* when accented), as in the first syllable of Ar. *qattala* = Syr. *qaṭṭēl* = Heb. *qiṭṭēl*. But the second syllable of the same word shows Syriac siding with Hebrew against Arabic. Again the primitive *ā* of Arabic is in the older (Nestorian) pronunciation of Syriac maintained, while in Jacobite Syriac and in Hebrew it passes into *ō*: thus Ar. *qātil* Nestorian *qāṭēl* = Jacobite and Hebrew *qōṭēl*. Again Syriac maintains the diphthongs *ai* and *au*, which in Hebrew have usually passed into *ē* and *ō*.

The *accent* plays much less part in lengthening and altering the vowels in Syriac than in Hebrew, but there are well-marked cases of lengthening from this cause.

A few words may now be said about the three main parts of speech—pronouns, nouns and verbs.

1. *Pronouns.*—As in the other Semitic languages, these stand almost entirely outside the system of triliteral roots, being mainly derived from certain demonstrative letters or particles. Each of the personal pronouns (except the 3rd plur.) exists in a longer and a shorter form: the one is used as a nominative and is a separate word, the other is attached to verbs and (in a slightly different form) to nouns to express the accusative or genitive. These pronominal suffixes are of much the same form as in Hebrew, but produce less change in the vowels of the words to which they are attached. Demonstrative adjectives and adverbs are formed by prefixing the syllable *hā* (= *ecce*, "behold") to other pronominal elements, and interrogatives similarly by prefixing the interrogative syllable *ay*; but there are other interrogative pronouns. The relative consists only of the letter *d* (indeclinable) prefixed to words.

2. *Nouns and Adjectives.*—The Syriac noun has three states—the *absolute* (used chiefly in adjectival or participial predicates, but also with numerals and negatives, in adverbial phrases, &c.), the *construct* (which, as in Hebrew, must be immediately followed by a genitive), and the *emphatic* (see above). There are only two genders and two numbers: the neuter gender is entirely wanting, and the dual number is not recognized in Syriac grammar, though there are plain traces of it in the language. The fem. sing. ending is absolute *ā*, construct *ath*, emphatic *tā* or *'tha*: thus the fem. sing. abs. is always identical in form with the masc. sing. emph. The plural endings are—masc. abs. *īn*, const. *ai*, emph. *ē*; fem. abs. *ān*, const. *āth*, emph. *āthā*. Syriac is not, like Arabic and Hebrew, confined to the use of the construct for the ordinary expression of the genitive or possessive relation: for it has a preposition (*d*) which expresses "of," "belonging to." The noun preceding this preposition may be in the emphatic state or may (as is usually the case when the noun is definite) have a pleonastic suffix. Thus "the son of the king" is more commonly expressed by *b'rā dh'malkā* or *b'rēh d'malkā* than by *bar malkā*, whereas the latter type would alone be permissible in Hebrew. And a genitive with prefixed *d* does not require the governing noun to precede it immediately, as must be the case when the construct is used. This is one of the many respects where Syriac has gained greater flexibility in syntax than Hebrew.

3. *Verbs.*—The Syriac verb is remarkable for having entirely lost the original passive forms, such as in Arabic can be formed in every conjugation and in Hebrew are represented by the Pual and Hophal. For these Syriac has substituted middle or reflexive forms with prefixed *eth* and a change in the last vowel. The simple active *q'ṭal* makes its passive *ethq'ṭel*; the intensive *qaṭṭēl* makes *ethqaṭṭal*; and the causative *aqṭēl* makes *ettaqṭal*. The inflexion of the verbs is, on the whole, more regular than in Hebrew: thus, to take one instance, the 3rd plur. fem. impf. *neqṭ'lān* corresponds better to 3rd plur. masc. *neqṭ'lūn* than does the equivalent Hebrew form *tiqṭōlnā* to *yiqṭ'lū*. But the most important peculiarity of Syriac verbs is again in the sphere of syntax, and shows the same progress towards flexibility which we found in the nouns. Whereas the Hebrew verb is devoid of real *tenses*, and only expresses an action as completed or as in process without indicating time past, present or future, Syriac has by the help of an auxiliary verb constructed a set of tenses. Thus we have—

Pres. *qāṭel*, "he kills," "he is killing" (sometimes "he is about to kill").
Impf. *qāṭel wā*, "he was killing."
Fut. *neqṭōl*, "he will kill."
Pf. or Aor. *q'ṭal* "he has killed," "he killed."
Plup. or Aor. *q'ṭal wā*, "he had killed," "he killed."

The same progress towards flexibility in syntax is seen in the copious supply of conjunctions possessed by Syriac. No doubt the tendency towards a more flowing construction of sentences was helped by the influence of Greek, which has also supplied a large stock of words to the Syriac vocabulary. (N. M.)

SYRIAC LITERATURE.[3] By *Syriac* is denoted the dialect of Aramaic which, during the early centuries of the Christian era, prevailed in Mesopotamia and the adjoining regions. The literary use of Syriac by Christians had its first centre in Edessa (Syr. Ūrhāi, modern Urfa), where, in all probability, the chief Syriac versions of the Bible were made. The use of the same dialect appears in the earliest Christian literature connected

[1] It may indeed be remarked that Syriac, which is generally more primitive in its sounds than Hebrew, shows a more advanced stage of weakening as regards the gutturals: thus in a good many forms it has substituted *ālef* for initial *hē*, and often shows a dislike for the presence of two gutturals in the same word, weakening one of them to *ālef*. A much more advanced stage of weakening is seen in some of the other dialects.

[2] With regard to this, Syriac has one great difference from Hebrew, viz. that final *ā* is indicated not by *hē*, but by *ālef*.

[3] The sketch of the history of Syriac literature here presented is based on Wright's great article in the 9th edition of the *Ency. Brit.*, which was afterwards published separately under the title of *A Short History of Syriac Literature* (London, 1894).

with such Mesopotamian cities as Nisībis, Amid, Mardīn, Taghrīth and Seleucia-Ctesiphon, as well as west of the Euphrates at such centres as Mabbogh (Hierapolis) and Aleppo, northwards at Malatiah and Maiperkaṭ and in the districts of Lake Van and Lake Urmia, and to the east and south-east of the Tigris in many places which from the 5th century onwards were centres of Nestorian Christianity within the Sasanian Empire. In Palestine and western Syria, the home of pre-Christian Aramaic dialects, the vernacular Semitic speech had under Roman dominion been replaced by Greek for official and literary purposes. Apparently this state of things lasted till after the Mahommedan conquest, for Barhebraeus[1] tells us that it was the caliph Walīd I. (A.D. 705–715) who, out of hatred to Christianity, replaced Greek by Arabic as the language of official documents at Damascus. Probably (as Duval suggests) the use of Syriac in these regions went hand in hand with the spread of the monophysite doctrine, for the liturgies and formulas of the Jacobite Church were composed in Syriac. Similarly the spread of Nestorian doctrines throughout the western and south-western regions of the Persian Empire was accompanied by the ecclesiastical use of a form of Syriac which differed very slightly indeed from that employed farther west by the Jacobites.

So far we have spoken only of the *Christian* use of Syriac. Of the *pagan* Syriac literature which issued mainly from Ḥarrān, a city about one day's journey south of Edessa, not a single example appears to have survived. From Christian writers we learn that Ḥarrān continued to be a seat of pagan worship and culture down to and even later than the Mahommedan era. A native of the city, Thābit ibn Ḳurra, in a passage from a Syriac work of his (now lost) quoted by Barhebraeus,[2] speaks of the paganism of Ḥarrān as distinguished by its steadfast resistance to Christian propaganda. "When many were subdued to error through persecution, *our* fathers through God were steadfast and stood out manfully, and this blessed city has never been defiled by the error of Nazareth." He goes on to attribute the world's science and civilization to pagan inventors; but it is not clear whether in this he is alluding specially to the culture of his own city. Anyhow, it is much to be regretted that no Syriac writing from Ḥarrān has survived.[3]

Syriac literature continued in life from the 3rd to the 14th century A.D., but after the Arab conquest it became an increasingly artificial product, for Arabic gradually killed the vernacular use of Syriac.

In the literature as it survives many different branches of writing are represented—homilies in prose and verse, hymns, exposition and commentary, liturgy, apocryphal legends, historical romance, hagiography and martyrology, monastic history and biography, general history, dogmatics, philosophy and science, ecclesiastical law, &c. But the whole is dominated by the theological and ecclesiastical interest. All chief writers were bishops, inferior clergy or monks, and their readers belonged to the same classes. When we put aside one or two exceptionally fine pieces, like the hymn of the soul in the apocryphal Acts of Thomas, the highest degree of excellence in style is perhaps attained in staightforward historical narrative—such as the account of the Perso-Roman War at the beginning of the 6th century by the author who passes under the name of Joshua the Stylite, or by romancers like him who wrote the romance of Julian; by biographers like some of those who have written lives of saints, martyrs and eminent divines; and by some early writers of homilies such as Philoxenus (in prose) and Isaac of Antioch (in verse). Nearly all the best writers are characterized by a certain naïve and earnest piety which is attractive, and not infrequently display a force of moral indignation which arrests attention. These latter qualities are even more apparent in poetry than in prose. There are indeed but few specimens of Syriac verse which exhibit high poetic quality; except for a fairly copious and occasionally skilful use of simile and metaphor, there is little of soaring imagination in Syriac poets. On the other hand there is much effective rhetoric, and much skilful play of language.[4]

As was to be expected, the better qualities of style were more often shown during the early centuries when the language was still a living speech. After it had been supplanted by Arabic in the ordinary intercourse of life its literary use was more and more affected by Arabic words and constructions, and its freedom as a vehicle of thought was much impaired. Nevertheless, so late as the 13th century it was still an effective instrument in the hands of the most many-sided of Syriac authors, the eminent Barhebraeus.

For the general history of culture the work of Syriac writers as *translators* is, perhaps, as important as any of their original contributions to literature. Beginning with the earliest versions of the Bible, which seem to date from the 2nd century A.D., the series comprises a great mass of translations from Greek originals—theological, philosophical, legendary, historical and scientific. In a fair number of cases the Syriac version has preserved to us the substance of a lost original text. Often, moreover, the Syriac translation became in turn the parent of a later Arabic version. This was notably the case with some of the Aristotelian writings, so that in this field, as in some others, the Syriac writers handed on the torch of Greek thought to the Arabs, by whom it was in turn transmitted to medieval Europe. The early Syriac translations are in many cases so literal as to do violence to the idiom of their own language; but this makes them all the more valuable when we have to depend on them for reconstructing the original texts. The later translators use greater freedom.[5] It was not from Greek only that translations were made into Syriac. Of translations from Pahlavī we have such examples as the version of pseudo-Callisthenes' *History of Alexander*, made in the 7th century from a Pahlavī version of the Greek original—that of *Kalilah and Dimnah* executed in the 6th century by the periodeutēs Bōdh—and that of *Sindbad*, which dates from the 8th century; and in the late period of Syriac literature, books were translated from Arabic into Syriac as well as vice versa.

All our historical sources support the view taken above that Edessa, the capital of the kingdom which the Greeks and Romans called Osrhoene, was the earliest seat of Christianity in Mesopotamia and the cradle of Syriac literature. But as to the date and circumstances of its evangelization we have little reliable information. The well-known legend of the correspondence of Abgar Ukkāmā, king of Edessa, with Christ and the mission of Addai to Edessa immediately after the Ascension was accepted as true by the historian Eusebius (†340) on the faith of a Syriac document preserved in the official archives of the city. An amplified form of the same story is furnished by the *Doctrine of Addai*, an original Syriac work which survives complete in a St Petersburg MS. of the 6th century, and is also represented by fragments in other MSS. of the 5th and 6th centuries. This work was probably written at Edessa about the end of the 4th century. It adds many new features to the shorter form of the story as given by Eusebius, among which is the noteworthy promise of Christ about the impregnability of the city—"Thy city shall be blessed and no enemy shall ever henceforth obtain dominion over it." This is probably a later addition made to the legend at a time when such facts as the capture of Edessa by Lusius Quietus in 116 and its second capture and the destruction of its kingdom by the Romans in 216 had faded from memory.[6]

[1] *Chron. syr.*, ed. Bruns, p. 120, ed. Bedjan, p. 115; cited by Duval, *Litt. syr.*[3], p. 5.

[2] *Chron. syr.*, ed. Bruns, p. 176, ed. Bedjan, p. 168. Thābit was the author of about 16 Syriac works, of which the majority survived in the 13th century, but all are now lost. Of his 150 Arabic treatises a few at least survive; see Brockelmann, *Geschichte der arabischen Litteratur*, i. 217 seq.

[3] On this subject, see especially Chwolsen's *Ssabier und Ssabismus*.

[4] On the mechanism of Syriac verse, see Duval's admirable section on *la poésie syriaque* (*Litt. syr.*[3], p. 10 sqq.).

[5] Cf. Duval, *op. cit.* p. 303 seq.

[6] Cf. Tixeront, *Origines de l'Église d'Édesse*, p. 93, and Duval, *op. cit.* p. 99. The above view is more probable than that taken by F. C. Burkitt (*Early Eastern Christianity*, p. 14), that Eusebius knew of Christ's promise as part of the letter to Abgar, and purposely suppressed it as inconsistent with historical facts.

But whether in its longer or its shorter form, the whole narrative must be pronounced unhistorical. In all probability the first king of Osrhoene to adopt Christianity was Abgar IX., son of Ma'nū, who reigned from A.D. 179 to 214 or 216, and the legend has confounded him with an earlier Abgar, also son of Ma'nū, who reigned first from B.C. 4 to A.D. 7 and again from A.D. 13 to 50.[1] A contemporary of Abgar IX. at Edessa was the famous Bardaiṣān, himself a convert from heathenism, who was of noble birth and a *habitué* of the Edessene court. It was no doubt partly under his influence—also possibly in part through impressions received by Abgar during his visit to Rome about A.D. 202—that the king's conversion took place. But Christianity must have reached Edessa some thirty to fifty years earlier. Our oldest native historical document in Syriac—the account of a severe flood which visited Edessa in Nov. A.D. 201[2]—mentions "the temple of the church of the Christians" as overthrown by the flood. The form of this notice shows, as von Gutschmid and others have remarked, that Christianity was not yet the religion of the state; but it must for some time have had a home in Edessa. The same thing is seen from the fact that the heresy of the Marcionites was already showing itself in this district, for (in Tixeront's words) "heresies, in the first centuries at least, only spread in already constituted Christian communities." And by a skilful piecing together of the date furnished by the oldest Syriac versions of the Bible—such as the derivation of the Old Testament version from the Jews, and the almost exclusive use of Tatian's Diatessaron as the gospel of the Syriac Church down to the beginning of the 5th century—F. C. Burkitt has shown it to be probable that the preaching of Christianity at Edessa reaches back to the middle of the 2nd century or even to about the year 135.[3]

The Syriac versions of the Bible are treated elsewhere (see BIBLE) and may here be dismissed with a brief summary of facts and opinions. The received Syriac Bible or Vulgate (called the Pĕshiṭṭā or "simple" version from the 9th century onwards[4]) contains all the canonical books of the Old Testament.[5] In the New Testament, 2 Peter, 2 and 3 John, Jude and the Apocalypse were originally left out, but Syriac versions were made at a later time. The Peshitta version of the Old Testament must have been originally made mainly by Jews, of whom we know there were colonies in Mesopotamia in the 2nd century. The translation was executed entirely from the Hebrew, but underwent later revision which brought it more into conformity with the LXX—this to a greater degree in some books than in others. The Peshitta New Testament—according to the convincing theory which at present holds the field[6]—is not the oldest form of the Syriac version, at least as regards the Gospels. From the beginning of the 3rd to the beginning of the 5th century Tatian's Harmony or Diatessaron—whether originally compiled in Syriac, or compiled in Greek and translated into Syriac—was the current form of gospel in the Syriac Church. The text of the Gospels underlying it "represents the Greek text as read in Rome about A.D. 170." Slightly later was made the Old Syriac version of the separate Gospels, which survives in two MSS.—the Curetonian and the Sinaitic—in two differing forms: but this never obtained much currency. Its text "represents, where it differs from the Diatessaron, the Greek text as read in Antioch about A.D. 200." Then at the beginning of the 5th century, by the efforts of the masterful Rabbūlā, who was bishop of Edessa from 411-412 to 435, a new version or recension of the Gospels was made and incorporated in the Peshitta or Vulgate, the use of the Diatessaron being henceforth proscribed. Rabbūlā's text of the Gospels "represents the Greek text as read in Antioch about A.D. 400." The history of the Peshitta rendering of the Acts and Epistles is less clear; apparently the earliest Syrian writers used a text somewhat different from that which afterwards became the standard.[7]

Of the large number of Apocryphal books existing in Syriac[8] the majority have been translated from Greek, one or two (such as *Bar Sīrā* or *Ecclesiasticus*) from Hebrew, while some (like the *Doctrine of Addai* above referred to) are original Syriac documents. Special mention may be made here of the tale of Aḥīḳār—the wise and virtuous secretary of Sennacherib, king of Assyria—and of his wicked nephew Nādhān. This is the Syriac version of a narrative which has had an extraordinary vogue in the world's literature. It is now known to have existed in Aramaic as far back as the 5th century B.C., appearing on Jewish papyri which were lately discovered by the German mission to Elephantine.[9] It appears to be traceable in its Greek dress in writings of the philosopher Democritus and the dramatist Menander; it was certainly known to the author of Tobit and perhaps to the author of Daniel; some would trace its influence in the New Testament, in the parable of the wicked servant and elsewhere; it was known to Mahomet and is referred to in the Koran; it has been included among the tales in the *Arabian Nights*; and it survives in a good many versions ancient and modern. The old Syriac version, which is to be found in a number of MSS., was probably made from an early Aramaic version, if not from the original itself (which must surely have been Semitic). The Syriac has in turn become the parent of the Arabic, Armenian and Ethiopic—possibly also of the Greek and Slavonic versions.[10]

Another deeply interesting Syriac Apocryphon is the *Acts of Judas Thomas* (*i.e.* Judas the Twin), which is included in the collection of *Apocryphal Acts of the Apostles*. The *Acts of Thomas* is now generally recognized to be an original Syriac work (or "novel," as Burkitt calls it), although a Greek version also exists. It seems to have arisen in Gnostic circles, and its tendency is wholly in favour of asceticism and celibacy. Among its peculiarities is the fact that Judas Thomas is regarded as the twin brother of Christ. The author has incorporated in it the finest poem to be found in all Syriac literature, the famous Hymn of the Soul. This depicts the journey of the soul from heaven to earth, its life in the body, and its final return to the heavenly home, under the figure of a Parthian prince who is sent from the court of his parents to the land of Egypt to fetch the serpent-guarded pearl; after a time of sloth and forgetfulness he fulfils his quest, and returns triumphant and again puts on the heavenly robe. According to Burkitt, the hymn must have been composed before the fall of the Arsacids and the commencement of the Sasanian Empire in 224. It is plainly Gnostic and may perhaps have been composed by Bardaiṣān or his son Harmonius.[11]

Among recent editions of Apocrypha in Syriac may be mentioned those of the *Apocalypse of Baruch*, the *Epistle of Baruch*,

[1] See especially Lipsius, *Die edessenische Abgar-Sage* (1880), and the brilliant analysis of the legend by A. von Gutschmid in *Mém. de l'acad. impér. des sciences de St Pétersbourg*, tome xxxv. No. 1. The above dates for the kings' reigns are taken from von Gutschmid.

[2] Incorporated in the *Chronicle of Edessa* (Hallier's edition, p. 145 sqq.).

[3] *Early Eastern Christianity*, Lecture II.

[4] See the explanation in Burkitt, *op. cit.* p. 41 seq.

[5] The MSS. which contain the Syriac *Massorah* or tradition of the reading of the text pass over Chronicles, Ezra and Nehemiah, and in the case of the Nestorians also Esther. But all these books are quoted by Aphraates.

[6] That of F. C. Burkitt. See especially his *S. Ephraim's Quotations from the Gospel* (Cambridge, 1901); *Evangelion da-mepharreshe* (Cambridge, 1904), and the above cited Lecture.

[7] For the later Monophysite versions, none of which attained much popularity, see Wright's *Syr. Lit.* pp. 13–17, and for the single Nestorian attempt at revision, ibid. p. 19.

[8] See the lists in Wright, *op. cit.* pp. 5 seq. 25–27, and Duval, *Litt. Syr.*[3] ch. viii.

[9] See F. Nau, *Histoire et sagesse d'Ahikar l'Assyrien* (Paris, 1909), p. 288 sqq.

[10] See especially *The Story of Ahikar from the Syriac, Arabic, Armenian, Ethiopic, Greek and Slavonic Versions*, by F. C. Conybeare, J. R. Harris and A. S. Lewis (Cambridge, 1898); and Nau, *op. cit.* The latter has a very full bibliography.

[11] Of the *Apocryphal Acts of the Apostles* there is the well-known edition and translation by Wright (London, 1871); the *Acts of Judas* were re-edited by Bedjan in the 3rd volume of *Acta martyrum et sanctorum* (Paris, 1892); of the *Hymn of the Soul* there is a fresh edition and translation by A. A. Bevan (Cambridge, 1897). See also Lecture VI. in Burkitt's *Early Eastern Christianity*.

and the *Testament of Adam* by M. Kmosko (Graffin's *Patrologia Syriaca*, vol. ii.).

Lives of saints and martyrs form a large group among Syriac books. Among such documents connected with the early history of Edessa we have, besides the *Doctrine of Addai*, certain martyrdoms, those of Sharbēl and Barsamyā assigned to the reign of Trajan, and those of Guryā and Shāmōnā and of the Deacon Habbībh under Diocletian and Licinius. All these documents, like *Addai*, belong probably to the 2nd half of the 4th century, and are quite unreliable in detail for the historian,[1] though they may throw some light on the conditions of life at Edessa under Roman government. There are also accounts of martyrdoms at Samosāta (Assemani, *Acta Mart.* ii. 123–147), including that of St Azazail recently published by Macler (Paris, 1902). But the great bulk of the Syriac martyrdoms have their scene farther east, within the Persian dominions.

The life and writings of Bardaiṣān, "the last of the gnostics," and in some sense the father of Syriac literature and especially of Syriac poetry, have been treated in a separate article. *The Book of the Laws of the Countries*, which embodies his teaching, was re-edited in 1907 by F. Nau (this also in the 2nd volume of Graffin's *Patrologia*).

An early Syriac document, probably of the 2nd or 3rd century, is the *Letter of Mārā son of Serapion*, which was edited by Cureton in his *Spicilegium Syriacum*. It is almost the only exception to the rule that all surviving Syriac literature is Christian. The author is in sympathy with Christianity, but is himself an adherent of the stoic philosophy. His home appears to have been at Samosāta.[2]

By the beginning of the 4th century much progress had been made with the organization of the Christian church not only within the Roman district of Mesopotamia, but also to the east and south-east within the Sasanian Empire, round such centres as Seleucia-Ctesiphon on the Tigris (near Baghdad), Karkā dĕ-Bēth Sĕlōkh (modern Kerkuk) and Bēth Lāpāt or Gundēshābhōr (in the modern province of Luristan).[3] The adoption of Christianity by Constantine as the official religion of the Roman Empire had an unfortunate effect on the position of the Christians in Persia. They were naturally suspected of sympathizing with the Roman enemies rather than with their own Persian rulers. Accordingly when Sapor II. (310–379) declared war on Rome about 337, there ensued almost immediately a somewhat violent persecution of the Persian Christians, which continued in varying degrees for about 40 years. One result of this and later persecutions of the same kind has been to enrich Syriac literature with a long series of *Acts of Persian Martyrs*, which, although in their existing form intermixed with much legendary matter, nevertheless throw valuable light on the history and geography of western Persia under Sasanian rule.[4] One of the earlier martyrs was Simeon bar Sabbā'ē, bishop (? catholicus) of Seleucia from about 326 to 341 in succession to Papa, who in the face of opposition from other bishops had organized the church of Persia under the primacy of Seleucia. The *Martyrdom* of Simeon exists in two recensions which have been separately edited by M. Kmosko.[5] Another early martyr was Millēs, bishop of Susa, who had distinguished himself in the opposition to Papa.[6]

The two most important 4th-century writers—Aphraates and Ephraim—are dealt with in separate articles. The importance of the former lies in the simple cast of his religious thought, his independence of theological formulas, his constant adherence to the letter of Scripture, his quaint exegesis, and the light he throws on the circumstances of his time, especially (1) the feeling between Jews and Christians, and (2) the position and sympathies of the Christian subjects of Sapor II. The position and character of Ephraim are very different. He is the typical exponent in Syriac of unbending Catholic orthodoxy. He impressed his countrymen more than any other single writer, partly no doubt by his enormous fecundity in writing, but more by the stern piety and uncompromising dogmatism which pervade his works.

In the 2nd half of the 4th century lived the monk Gregory, who wrote a treatise on the monastic life. He spent part of his life in Cyprus, and was a friend of Epiphanius, bishop of Salamis. To the information given by Assemani (*B.O.* i. 170 seq.) we can now add the statements of Īshō'-dĕnaḥ[7] that he was a Persian by birth, and after being a merchant was led by a series of visions to take monastic vows. After a training at Edessa, he lived for a long time at Mt Īzlā in Mesopotamia, whence he proceeded to Cyprus, but returned to Mt Īzlā shortly before his death. His book on the monastic life mentioned by 'Abhdīshō' is not known to survive; but some discourses and a letter of his are still extant.

Before leaving the 4th century we may mention two other writers who probably both lived on into the 5th—Balai and Cyrillōnā. The former was the author of a good many poems; the longest—which is however by some attributed to Ephraim[8]—is the work in 12 books on the history of Joseph, of which a complete edition was published by Bedjan in 1901. Other poems of his were edited by Overbeck in *S. Ephraemi Syri*, &c., *opera selecta*, pp. 251–336; and these have since been supplemented by Zetterstéen's edition of a large number of his religious poems or metrical prayers (*Beiträge zur Kenntniss der religiösen Dichtung Balais*, Leipzig, 1902). His favourite metre was the pentasyllabic. Cyrillōnā composed a poem on the invasion of the Huns in 395,[9] and is by some regarded as identical with Ephraim's nephew Abhsamyā, who in 403–404 "composed hymns and discourses on the invasion of the Roman empire by the Huns."[10]

The 5th century was a time of storm and conflict in the churches of Mesopotamia and Persia, as in other parts of the Christian world. The teaching of Apollinarius that in Christ the Divine Word took the place of the human rational soul, thus seeming to do away with his possession of a true humanity, had led to a reaction by Paul of Samosāta, Diodore of Tarsus, Theodore of Mopsuestia, and Nestorius of Constantinople. Though with some points of difference, they agreed in emphasizing the permanence of the two separate natures in Christ, united but not mingled or confused, and laid stress on the reality of our Lord's human experience. One question on which great contention arose was as to the propriety of applying to the Divine nature attributes which belonged to the human nature—*e.g.* birth from a human mother—and vice versa. Hence the great dispute about the application to the Virgin Mary of the epithet θεοτόκος. It seems to have been the objection of Nestorius to the use of this expression which mainly led to his condemnation and deposition at the Council of Ephesus (431) under the influence of Cyril, when as patriarch of Constantinople (428–431) he had distinguished himself by his zeal for Nicene orthodoxy.[11]

At Edessa the result of the conflict between the Nestorians and their opponents was long doubtful. When Rabbūlā, the fierce anti-Nestorian and friend of Cyril, died in 435, he was succeeded in the bishopric by Ibas, who as head of the famous "Persian

[1] Burkitt (*op. cit.* p. 21 seq.) endeavours to claim a higher value for the narratives about Guryā, Shāmōnā and Habbībh, on the ground that these have left more trace in the later literature; but it is to be feared that all five martyrdoms are turned out in the same legendary mould.

[2] Cf. Duval, *Litt. Syr.*[3] p. 241 seq.

[3] On the origin and early history of Persian Christianity see especially J. Labourt, *Le Christianisme dans l'empire Perse* (Paris, 1904), chaps. i. and ii.

[4] See many of the texts in Bedjan's *Acta martyrum et sanctorum* (Paris, 1890–1896). The valuable geographical results are exhibited in G. Hoffmann's *Auszüge aus syrischen Akten persischer Märtyrer* (Leipzig, 1880).

[5] Graffin's *Patrologia*, ii. 661–1045. Of the epistles, hymns, &c., attributed to Simeon nothing appears to survive but one or two hymns (ibid. 1048–1055). The *Martyrdom* had been previously edited by Assemani and by Bedjan.

[6] His history is in Assemani, *Acta mart.* i. 66 sqq., and Bedjan, ii. 260 sqq.

[7] *Book of Chastity*, par. 12.

[8] It is in Ephraim's favourite metre, the heptasyllabic, and all the MSS. but one attribute it to him.

[9] *Chron. Edess.* par. 40.

[10] Ibid. par. 47.

[11] New light on the theological position of Nestorius is to be obtained from the long-lost *Book of Heraclides*, a work of his own which has turned up in a Syriac version and has just been published by Bedjan.

school " in the city had done much to inculcate on his pupils the doctrines of Theodore of Mopsuestia. But the feeling against the Nestorian party grew in strength, till on the death of Ibas in 457 the leading Nestorian teachers were driven out of Edessa. The Persian school continued to exist for another 32 years, but was finally closed and destroyed by order of the emperor Zeno in 489. The Nestorian teachers then started a great school at Nisībis (which had been under Persian rule since Jovian's humiliating treaty of 363). By the energetic efforts of Barṣāumā, bishop of that city, practically the whole church of Persia was won over to the Nestorian creed. Western Syria, on the contrary, had partaken with Alexandria in the reaction from Nestorianism which finally crystallized in the Monophysite doctrine, that spread so widely through Egypt and Western Asia towards the end of the 5th century.

At the beginning of this century one of the most able and influential men in the Syriac-speaking church was Mārūthā, bishop of Maiperḳaṭ or Martyropolis. Without entering on the details of his ecclesiastical activity,[1] we may note that he was twice associated with embassies from the Roman emperor to Yazdegerd I. (399–420); that along with Isaac, patriarch of Seleucia (390–410), he obtained from the Persian monarch a concordat which secured a period of religious toleration; and that he arranged for and presided at the Council of Seleucia in 410, which adopted the full Nicene creed and organized the hierarchy of the Persian Church. As a writer he is chiefly known as the reputed author of a collection of martyrologies which cover the reigns of Sapor II., Yazdegerd I. and Bahram V.[2] By his history of the Council of Nicaea he made a great contribution to the education of the Persian Church in the development of Christian doctrine.

Rabbūlā, the powerful and energetic bishop of Edessa who withstood the beginnings of Nestorianism, and who gave currency to the Peshitta text of the four Gospels, abolishing the use of the Diatessaron, is dealt with in a separate article.

The next bishop of Edessa, Ibas, who succeeded in 435 at the death of Rabbūlā, proved himself a follower of the Nestorian doctrine (see above). As a teacher in the Persian school of Edessa he had translated, probably with the help of his pupils, certain works of " the Interpreter," *i.e.* Theodore of Mopsuestia. Among these may have been the commentary on St John of which the complete Syriac version was published by Chabot in 1897. He may possibly have translated a work of Aristotle.[3] To the Nestorian movement in Persia he rendered useful service by his letter to Mārī of Bēth Hardashēr, in which he maintained the tenets of Diodore and Theodore, while allowing that Nestorius had erred.[4] On the ground of his writings he was condemned and deposed by the " robber synod " of Ephesus (449), but was restored by the Council of Chalcedon (451), after he had anathematized Nestorius. His death in 457 was followed by a strong anti-Nestorian reaction at Edessa, which led to the expulsion of many of the leading teachers.

On Isaac of Antioch, " one of the stars of Syriac literature," see the special article. In spite of his over-diffuseness, he is one of the most readable of Syriac authors.

A Nestorian contemporary of Isaac, Dādhīshō', who was catholicus of Seleucia from 421 to 456, composed commentaries on Daniel, Kings and Ecclesiasticus. His chief importance in the history of the Persian Church lies in his having induced a synod of bishops to declare that church independent of the see of Antioch and of the " Western Fathers " (Labourt, p. 122 sqq.).

The most powerful missionary of Nestorianism during the 2nd half of the 5th century was Barṣāumā of Nisībis, whom his opponents called " the swimmer among the reeds," *i.e.* the wild boar. Born probably between 415 and 420 he imbibed Nestorian doctrine from Ibas at the Persian school of Edessa, but was driven out in 457 on the death of his master, and went to be bishop of Nisībis. In a succession of missionary journeys he succeeded, partly by persuasion and partly (if his enemies are to be believed) by violence, in attaching to Nestorianism nearly all the Christian communities of Persia, with the exception of Taghrīth, which was always strongly Monophysite. He had many quarrels with his ecclesiastical superior the catholicus of Seleucia, but finally made peace with Acacius soon after the accession of the latter in 484. Among other severities towards the Monophysites, he persuaded the Persian king Pērōz (457–484) to banish many of them into the Roman dominions. One of his great aims was to secure for the Nestorian clergy freedom to marry, and this was finally sanctioned by a council at Seleucia in 486 (Labourt, *op. cit.*, chap. vi.). Barṣāumā must have been bishop of Nisībis for nearly 40 years, but was dead by 496. His writings seem to have been chiefly liturgical: he gave the first set of statutes to the school of Nisībis, which was founded during his bishopric.

His fellow-worker Narsai, whom the Jacobites called " the leper," but the Nestorians " the harp of the Holy Spirit," apparently accompanied Barṣāumā from Edessa to Nisībis, where according to Barhebraeus he lived for 50 years. Barṣāumā appointed him head of the new school, where he taught rigidly Nestorian doctrine. He was a copious writer, especially in verse. Many of his poems have now been published.[5] His theological position is clearly defined in a homily on the three doctors—Diodore, Theodore and Nestorius—published by the Abbé Martin in the *Journal asiatique* for July 1900.

On the less important companions of Barṣāumā and Narsai-Mārī, Acacius and Mīkhā, see Wright (*op. cit.* pp. 59 seq., 63 seq.). The M'anā who accompanied them and became bishop of Rēwardashēr in Persia was not, as Barhebraeus supposed, the catholicus of Seleucia who held office in 420, but a much younger man. Like Ibas he had been employed at Edessa in translating the commentaries of Theodore.

Among the early Monophysites were two of the best of Syriac writers—Jacob of Sĕrūgh and Philoxenus of Mabbōgh, who have been treated in special articles. The one wrote mainly in verse, the other in prose. See also JOSHUA THE STYLITE.

Another early Monophysite was Simeon of Bēth Arshām, who by a series of journeys and disputations within the Persian empire did all he could to prevent the triumph of Nestorianism among the Persian Christians. He had considerable success at the time, but the ground he had won was soon reconquered by his opponents, except at Taghrīth and the surrounding district. It was after a successful disputation in presence of the Nestorian catholicus Bābhai (497–502/3) that Simeon was made bishop of Bēth Arshām, a town near Seleucia. He made several journeys to Constantinople, where he enjoyed the favour of the empress Theodora. It was there he died, probably about 532–533. His biography was written by John of Asia in the collection of lives of eastern saints which has been edited by Land (*Anecd. syr.* vol. ii.). His literary productions consist only of a liturgy and two exceedingly interesting letters. The one has for its subject Barṣāumā and the other Nestorian leaders in Persia, and gives a highly malicious account of their proceedings. The other, which has been often edited,[6] is an account of a severe persecution which the Himyarite Christians of Najrān in south-west Arabia underwent in 523, at the hands of the king of Yemen. As Simeon had repeatedly visited al-Ḥirah and was in touch with the Arab kingdom which centred there, his letter is a document of first-rate historical importance.

Mention should be made of two other early Monophysite leaders who suffered persecution at the hands of the emperor Justin I. (518–527). The one is John of Tellā, author of 538 canons,[7] answers to questions by the priest Sergius, a creed and an exposition of the Trisagion. His life was written by his disciple Elias, and also by John of Asia. The other, John bar Aphtōnyā, was the founder of the famous monastery of Ḳenneshrē, opposite

[1] See Labourt, *op. cit.*, especially pp. 87–90, 92–99.

[2] Some of these refer to events so late that they cannot be from his pen.

[3] See Duval, *Litt. syr.*[3], p. 247.

[4] Labourt, *op. cit.* p. 254 sqq.

[5] See Feldmann, *Syrische Wechsellieder von Narses* (Leipzig, 1896); Mingana, *Narsai, homiliae et carmina* (2 vols., Mosul, 1905); and other editions of which a list is given by Duval, p. 344 seq. Four of the homilies which deal with liturgical matters have been given in an English translation, accompanied with valuable notes, by R. H. Connolly (Cambridge, 1909).

[6] The best edition is Guidi's *La Lettera di Simeone Vescovo di Bēth-Arśām sopra i martiri omeriti* (Rome, 1881).

[7] Edited by Kuberczyk (Leipzig, 1901).

Jerābīs on the Euphrates, and wrote a commentary on the Song of Songs, a number of hymns and a biography of Severus, the Monophysite patriarch of Antioch (512–519).

The life of the great missionary bishop Jacob Burdĕ'ānā[1] or Baradaeus, from whom the Monophysite Church took its name of Jacobite, belongs rather to ecclesiastical than to literary history. A native of Tellā in Mesopotamia, he obtained the favour of the empress Theodora while on a mission to Constantinople, and resided in that city for fifteen years (528–543). At the request of the Arab king of Ghassān he was sent on a mission to the East after being consecrated bishop of Edessa; and the rest of his life was spent in organizing the Monophysite Church of eastern Syria. We possess two lives of him—one by John of Asia in his collection of biographies, and another which may have been written by a priest of Jacob's original monastery of Pĕsīltā. Both are to be found in the 2nd volume of Laud's *Anecdota syriaca*. An excellent modern biography and estimate of Jacob has been written by Kleyn.[2] A Syriac account of the removal of his remains from Alexandria, where he died in 578, to his old monastery of Pĕsīltā has been edited by Kugener in the *Bibliothèque hagiographique orientale*, pp. 1–26 (Paris, 1902). The activity of his life left him little time for writing, but he was the author of "an anaphora, sundry letters, a creed or confession of faith, preserved in Arabic and a secondary Ethiopic translation, and a homily for the Feast of the Annunciation, also extant only in an Arabic translation" (Wright).

A very different character from Jacob's was that of Sergius of Rās'ain, one of the best Greek scholars and ablest translators whom Syria has produced. Of his life little is known, and that little not wholly creditable. He wavered curiously in his ecclesiastical views, and ended by helping the persecutors of the Monophysite Church, to which he himself had belonged. He seems to have lived as a priest and physician at Rās'ain in Mesopotamia most of his life. About 535 he travelled on various ecclesiastical missions, and finally made a journey to Rome and thence to Constantinople (in this latter accompanied by the pope Agapetus). The result was to bring about the deposition and banishment of the Monophysites from the latter city. Sergius died almost immediately afterwards, in 536. Among the works which he translated into Syriac and of which his versions survive are treatises of Aristotle, Porphyry and Galen,[3] the *Ars grammatica* of Dionysius Thrax, the works of Dionysius the Areopagite, and possibly two or three treatises of Plutarch.[4] His own original works are less important, but include a "treatise on logic, addressed to Theodore (of Merv), which is unfortunately imperfect, a tract on negation and affirmation; a treatise, likewise addressed to Theodore, *On the Causes of the Universe, according to the Views of Aristotle, showing how it is a Circle*; a tract *On Genus, Species and Individuality*; and a third tract addressed to Theodore, *On the Action and Influence of the Moon*, explanatory and illustrative of Galen's Περὶ κρισίμων ἡμερῶν, bk. iii., with a short appendix 'On the Motion of the Sun'" (Wright). According to the historical compilation which passes under the name of Zacharias Rhetor, he also wrote a treatise on the faith.[5] Some of his translations were revised at a later time by Ḥonain ibn Isḥāḳ (†873).

Another translator from Greek was Paul, Monophysite bishop of Callinīcus or ar-Raḳḳah, who, being expelled from his diocese in 519, retired to Edessa and there occupied himself in translating into Syriac the works of Severus, the Monophysite champion who was patriarch of Antioch from 512 to 519. This version appears to be quite distinct from that used by the compiler of the chronicle of Zacharias,[6] and also from the version of "the 6th book of the select letters of Severus" which was made by Athanasius "presbyter of Nisībis" in 669 and has been edited by E. W. Brooks (London, 1902–1904).

That important legal work, *The Laws of the Emperors Constantine, Theodosius and Leo*, which was composed in Greek about 475, and "which lies at the root of all subsequent Christian Oriental legislation in ecclesiastical, judicial and private matters" (Wright), must have been repeatedly translated into Syriac. The oldest form is contained in a British Museum MS. which dates from the earlier part of the 6th century, and this was edited by Land (*Anecd. syr.* i. 30–64). A latter (probably Nestorian) recension is contained in a Paris MS., which was used along with the other by Bruns and Sachau in their exhaustive edition (*Syrisch-römisches, Rechtsbuch*, Leipzig, 1880). In *Notulae syriacae* (privately printed 1887) Wright edited the surviving fragment of a 3rd recension which is preserved in a 13th-century MS. at Cambridge. Finally Sachau has published three new redactions of the treatise from a MS. found at Rome in 1894 (*Syrische Rechtsbücher*, vol. i., Leipzig, 1907).

The last 5th-century author to be mentioned here is Aḥūdhemmēh, who was Jacobite metropolitan of Taghrīth from 559 till he was martyred by Khosrau Anōsharwān in 575. He wrote various philosophical works, also a treatise on grammar which is quoted by the later grammarian, John bar Zō'bi. A Syriac life of him has been published by F. Nau, who appends to it the surviving fragment of his treatise on the composition of man as consisting of soul and body.[7]

We may here take note of three important anonymous works, of which the first probably and the other two certainly belong to the 6th century.

The Mĕ'arrath gazzē or *Cave of Treasures*, translated and edited by C. Bezold (Leipzig, 1883–1888), is akin (as Duval remarks) to the *Book of Jubilees*. It is an imaginary history of the patriarchs and their descendants. The work derives its name from the picturesque story of the cave where Adam deposited the treasure of gold, myrrh and incense which he had brought away from paradise: the cave was used as a burying-place by him and his descendants until the deluge. After the precious relics together with the bones of Adam had been saved in the ark, they were transported by Shem and Melchizedek to Golgotha under the guidance of an angel.[8]

The tripartite narrative which is known as the *Romance of Julian* (the Apostate) has no claim to be regarded as an historical document. Its hero is Jovian, one of the feeblest of Roman emperors, and Julian is everywhere exhibited in flaming colours as the villain of the story. But as an example of Syriac prose style it is of the best, and the author at times shows considerable dramatic power.

A valuable historical source, though of small dimensions, is the *Chronicle of Edessa*, which gives a record of events from 132–131 B.C. to A.D. 540—at first exceedingly brief, but becoming somewhat fuller for the later years. It appears to be thoroughly reliable wherever it can be tested. It has been three times edited—first by Assemani in the *Bibliotheca orientalis* (i. 388–417), secondly by L. Hallier (Leipzig, 1892) with a translation, introduction and abundant notes, and thirdly by Guidi with a Latin version (in *Chronica minora*, Paris, 1903).

On John of Asia or Ephesus, the eminent Monophysite bishop and earliest Syriac church historian, see the separate article.

An historical work of somewhat similar character to John's is the compilation in 12 books which is generally known by the name of Zacharias Rhetor,[9] because the anonymous Syriac compiler has incorporated the Syriac version or epitome of a lost

[1] So called "because his dress consisted of a barda'thā, or coarse horse-cloth, which he never changed till it became quite ragged" (Wright).

[2] *Jacobus Baradaeus, de Stichter der syrische monophysietische Kerk* (Leiden, 1882).

[3] See the details in Wright, pp. 90 sqq.; and cf. especially A. Baumstark, *Aristoteles bei den Syrern vom V.–VIII. Jahrhundert* (Leipzig, 1900); and V. Ryssel, *Über den textkritischen Werth der syrischen Uebersetzungen griechischer Klassiker* (Leipzig, 1880–1881). The latter singles out the version of the pseudo-Aristotelian Περὶ κόσμου as a model of excellence in translation.

[4] On these last see Baumstark, *Lucubrationes syro-graecae* pp. 405 sqq. (Leipzig, 1894); and Duval, *Litt. syr.*[3] pp. 266 seq.

[5] Land, *Anecd. syr.* iii. 289.

[6] See Brooks and Hamilton's translation of the latter, p. 234.

[7] *Patrologia orientalis*, iii. 1 (Paris, 1906).

[8] Bezold's edition contains also an Arabic version.

[9] This author has hitherto been identified with Zacharias Scholasticus, who afterwards became bishop of Mitylene, but according to M. A. Kugener, *La Compilation historique de pseudo-Zacharie le Rhéteur* (Paris, 1900), this identification is a mistake.

Greek history written by that author. The Syriac work exists (not quite complete) in a British Museum MS. of about the beginning of the 7th century: this can be in part supplemented by an 8th-century MS. at the Vatican. From the latter Guidi published the interesting chapter (X. 16) which contains the description of Rome. The entire text of the London MS. was published by Land in the third volume of his *Anecdota syriaca*; and there is now an English translation by Hamilton and Brooks (London, 1899), and a German one by Ahrens and Krüger (Leipzig, 1899).

Of the other 6th-century Jacobite writers we need mention only Moses of Aggēl (*fl. c.* 550–570) who translated into Syriac some of the writings of Cyril, and Peter of Callinīcus, Jacobite patriarch of Antioch 578–591, who wrote a huge controversial treatise in 4 books, each of 25 chapters, against Damian, patriarch of Alexandria, as well as other less important works.

The Nestorian writers of the 6th century were numerous, but as yet we know little of their works, beyond what ʽAbhdīshoʽ tells us in his *Catalogue*. It will be sufficient to mention one or two. Joseph Hūzāyā (*i.e.* of al-Ahwāz or Khūzistan), who came third in succession to Narsai as head of the school of Nisībis, was the first Syriac grammarian and invented various signs of interpunction. Mārūthā, who was Nestorian catholicus of Seleucia from about 540 to 552[1] and a man of exceptional energy, made the only known attempt, which was, however, unsuccessful, to provide the Nestorians with a Bible version of their own. He was the author of many commentaries, homilies, epistles, canons and hymns. Paul the Persian, a courtier of Khosrau Anōsharwān, dedicated to the king a treatise on logic which has been published from a London MS. by Land in the 4th volume of his *Anecdota*. Bōdh the periodeutes is credited with a philosophical work which has perished, but is best known as the author of the old Syriac version of the collection of Indian tales called *Kalīlah and Dimnah*. He made it doubtless from a Pahlavī version. His translation, which was edited by Bickell with an introduction by Benfey, must be distinguished from the much later Syriac translation made from the secondary Arabic version and edited by Wright in 1884.[2] Ḥannānā of Ḥedhaiyabh, who nearly produced a disruption of the Nestorian Church by his attempt to bridge over the interval which separated the Nestorians from Catholic orthodoxy, was the author of many commentaries and other writings, in some of which he attacked the teaching of Theodore of Mopsuestia. An account of his theological position, derived from the treatise of Bābhai *De unione*, will be found in Labourt, *op. cit.* pp. 279 sqq. One of his followers, Joseph Ḥazzaya, was also a prolific writer.

"With the 7th century," as Wright remarks, "begins the slow decay of the native literature of the Syrians, to which the frightful sufferings of the people during the great war with the Persians in its first quarter largely contributed." The same process of decay was greatly promoted by the Arab conquest of Persia, achieved through the victory of Ḳādisīya in 636-637. The gradual replacement of Syriac by Arabic as the vernacular language of Mesopotamia by degrees transformed the Syriac from a living to a dead language. Apart from a few leading writers—such as Jacob of Edessa, the anonymous historian whose work has passed under the name of Dionysius of Tell-Maḥrē, Thomas of Margā, Dionysius Bar Ṣalībī, and Barhebraeus[3]—there are not enough names of interest to make it worth while to continue our chronological catalogue. It will be sufficient to group the more important contributors to each of the chief branches of literature.

1. *Theology.*—Here we may first mention George, Bishop of the Arabs (†724), who wrote commentaries on Scripture, and tracts and homilies on church sacraments, and finished the *Hexaēmeron* of Jacob of Edessa.[4] Bābhai the Elder, a leading Nestorian in the beginning of the 7th century and a prolific author, wrote many commentaries and theological discourses. Īshōʽyabh III., Nestorian catholicus from 647 to 657/8, wrote controversial tracts, religious discourses and liturgical works. Elias of Merv, who belongs to the 2nd half of the 7th century, compiled a *Catena patrum* on the Gospels and wrote many commentaries. Timothy I., catholicus 779–823, wrote synodical epistles and other works bearing on church law.[5] Moses bar Kēphā (†903), one of the most fertile of 9th-century authors, wrote commentaries, theological treatises and many liturgical works. Other important contributors to this sphere of literature were Ishōʽ bar Nōn (†827/8), John bar Zōʽbī (beginning of the 13th century), Jacob bar Shakkō (†1241), and the great Nestorian scholar ʽAbhdīshōʽ (†1318).

2. *History.*—Besides the important writers treated in separate articles, we need mention only four. Elias bar Shīnāyā, who in 1008 became Nestorian bishop of Nisībis, was the author of a valuable *Chronicle*, to which are prefixed numerous chronological tables, lists of popes, patriarchs, &c., and which covers by its narrative the period from A.D. 25 to 1018. Of this work, which exists in only one imperfect copy, the later portion was edited by Baethgen in 1884, and the earlier by Lamy in 1888. Another important *Chronicle* is that of Michael I., who was Jacobite patriarch from 1166 to 1199. Its range extends from the Creation to the author's own day, and it was largely used by Barhebraeus in compiling his own *Chronicle*. Till recently it was known only in an abridged Armenian version which was translated into French by V. Langlois (Venice, 1868): but the Syriac text has now been found in a MS. belonging to the library of the church at Edessa, and is in course of publication by J. B. Chabot. A work rather legendary than historical is the *Book of the Bee*, by Solomon of al-Baṣrah, who lived early in the 13th century.[6] Lastly, acknowledgment must be made of the great value of the Catalogue of Nestorian writers, by ʽAbhdīshōʽ of Nisībis, the latest important writer in Syriac. It was edited by Assemani in the 3rd part of his *Bibliotheca orientalis*, and has been translated into English by Badger.

3. *Biography, Monastic History, &c.*—Besides the important work by Thomas of Margā (*q.v.*) the following deserve special mention. Sāhdōnā, who was a monk in the Nestorian monastery of Bēth ʽĀbhē (the same to which Thomas of Margā belonged two centuries later) and afterwards a bishop early in the 7th century, wrote a biography of and a funeral sermon on his superior Mār Jacob who founded the monastery, and also a long treatise in two parts on the monastic life, of which all that survives has been edited by P. Bedjan (Paris, 1902). Whilst accompanying the catholicus Ishōʼyabh II. (628–644) on a mission to Heraclius, Sāhdōnā was converted, apparently to catholicism,[7] and thereby caused much scandal in the East. The chief events in his life are narrated by Ishōʽdĕnaḥ.[8] Another, Nestorian who, a few years later, wrote ecclesiastical biographies and other theological works was Sabhrīshōʽ Rusṭam, who lived at Mount Izlā and other monasteries. In the beginning of the 8th century David of Bēth Rabban, also a Nestorian monk, wrote, besides a geographical work, "a monastic history, called *The Little Paradise*, which is frequently cited by Thomas of Margā." A more important work is *The Book of Chastity*, by Ishōʽdĕnaḥ, who according to ʽAbhdīshōʽ was bishop of Ḳaṣrā—but read Baṣrā—about the end of the 8th century. This work is a collection of lives of holy men who founded monasteries in the East, and is a valuable historical source. The work itself, or an abridgment of it, was discovered and published for the first time by J. B. Chabot (Rome, 1896).[9] As the last under this head we may mention a late anonymous biography, that of the catholicus Yabhalāhā III. (1281–1317), which throws much light on the relations of the early Mongol kings with the heads of the church in their dominions. Among other interesting features it contains information about the Nestorian Church of China in the 13th century—Yabhalāhā was a native of Peking—an account of a journey through Central Asia, and a description of a visit to Europe by Rabban Ṣaumā, the friend of the catholicus.[10]

4. *Philosophy and Science.*—Special mention may be made of ʽĀnānīshōʽ of Ḥedhaiyabh (middle of 7th century) well known as the author of a new recension of the *Paradise* of Palladius, and also the author of a volume on philosophical divisions and definitions; Romanus the physician (†896), who wrote a medical compilation, a commentary on the Book of Hierotheus, a collection of Pythagorean maxims and other works; Moses bar Kēphā, the voluminous writer above referred to; the famous physician Ḥonain ibn Iṣḥāḳ

1 See a full account of his career in Labourt, *Le Christianisme dans l'empire perse*, pp. 163–191.

2 Of this there is an English translation by Keith Falconer (Oxford, 1884).

3 These have all been dealt with in separate articles.

4 George's part has been translated into German by V. Ryssel (Leipzig, 1891).

5 See O. Braun's article in *Oriens christianus*, i. 138–152; and Labourt, *De Timotheo I. Nestorianorum patriarcha* (Paris, 1904).

6 Text and translation, by E. A. W. Budge (Oxford, 1886).

7 See H. Goussen, *Martyrius-Sahdonas Leben und Werke* (Leipzig, 1897).

8 *Le Livre de la chasteté* (ed. Chabot, pp. 67 sqq.).

9 A fresh edition by Bedjan forms an appendix to his edition of Thomas of Margā (Paris, 1901).

10 The text has been twice edited by Bedjan (Paris, 1888 and 1895), and there is a French translation, with copious notes, by Chabot (Paris, 1895); cf. also *Journ. As.* (1889), pp. 313 sqq., and *Eng. Hist. Rev.* xiv. 299 sqq.

(†873), who wrote chiefly in Arabic, but deserves mention here by his services to Syriac grammar and lexicography, and still more by his translations of Greek philosophical and scientific works into Syriac[1] and from Syriac into Arabic, becoming in a sense the founder of a school of translators; and Jacob bar Shakkō, whose work called the *Dialogues* treats of grammar, rhetoric, poetry, logic, philosophy and science.

5. *Grammar and Lexicography.*—Several of the authors in this department have already been mentioned. The more important, besides Jacob of Edessa and Barhebraeus, are 'Ānānīshō' of Ḥēdhaiyabh, Ḥonain ibn Iṣḥāḳ, his pupil Bar 'Alī, Bar Sarōshwai (early 10th century), Bar Bahlūl (middle of 10th century), Elias of Ṭirhān (†1049), Elias bar Shīnāyā (above), John Bar Zō'bī (beginning of 13th century) and Jacob bar Shakkō.

Apart from the numerous editions of Syriac texts by M. Paul Bedjan, most of which have been cited above, nearly all the texts recently edited are included in one or other of three comprehensive series now running—viz. (1) *Patrologia syriaca* (Paris, 1894); (2) *Corpus scriptorum christianorum orientalium—scriptores syriaci* (Paris, 1907); (3) *Patrologia orientalis* (Paris, 1907). (N. M.)

SYRIANUS, a Greek Neoplatonist philosopher, and head of the school at Athens in succession to Plutarch. He is important as the teacher of Proclus, and, like Plutarch and Proclus, as a commentator on Plato and Aristotle. His best-known extant work is a commentary on the *Metaphysics* of Aristotle. He is said to have written also on the *De coelo* and the *De interpretatione* of Aristotle and on Plato's *Timaeus*. A treatise on the *Staseis* of Hermogenes was published under his name by Walz in 1833. His views were identical with those of Proclus, who regarded him with great affection and left orders that he should be buried in the same tomb.

SYRINGE (Gr. σῦριγξ, reed, pipe), a hydraulic instrument, based on the principle of the pump, for the drawing up and ejecting of liquids. The ordinary form is that of a glass or metal tube ending in a pointed nozzle and fitted with an air-tight piston-rod and handle. The nozzle is inserted in the liquid, which enters the cylinder by atmospheric pressure when the piston-rod is drawn up. On pushing back the piston the fluid is ejected in a jet through the nozzle. In sizes varying from the needle-pointed hypodermic syringe to the abdominal syringe, it is a common surgical implement used for the injection of fluids into the body or for the washing of wounds and cavities. The smaller syringes are made of glass, the larger of metal; the most common medical syringes consist of a length of india-rubber tubing, one end terminating in a nozzle of ivory or other easily cleaned material, in the centre is a bulb or ball which under pressure draws up the liquid through the free end of the tube which is placed in the vessel containing it. There are a very large number of different types of syringe used in surgical practice. A larger syringe of metal, with a flat perforated nozzle is used as a garden implement for watering plants.

SYRINX (σῦριγξ), the Greek name for the pan-pipes. The principle on which it works is that of the stopped pipe, but it is blown in the same manner as the ancient Egyptian nay or oblique flute. The pipes composing it were stopped at one end, so that the sound waves had to travel twice the length of the pipe, giving out a note nearly an octave lower than that produced by an open pipe of equal length. The breath directed horizontally across the open end, impinged against the sharp inner edge of the pipes, creating the regular series of pulses which generate the sound waves within the tubes. The syrinx consisted of a varying number of reeds, having their open ends or embouchures in a horizontal line and their stopped ends, formed by the knots in the reed, gradually decreasing in length from left to right. Each pipe gave out one note, but by overblowing, *i.e.* increased pressure of breath and tension of lips, harmonies could be obtained.

The syrinx or pan pipes owes its double name to ancient Greek tradition, ascribing its invention to Pan in connection with a well-known legend of the Arcadian water-nymph "Syrinx."[2] The exact form of the instrument and the number of pipes (10) at the beginning of the third century B.C. is shown in one of the Idyllia figurata,[3] in which the legend is repeated. The pandean pipes continued in favour with the rustic populations of the West long after the organ evolved from it had eclipsed this humble prototype. The syrinx was in use during the middle ages, and was known in France as *frestel* or *frêtiau*, in medieval Latin as *fistula panis*, and in Germany as *Pansflöte* or *Hirtenpfeife* (now *Papagenoflöte*). At the beginning of the 19th century a revival of the popularity of this instrument took place, and quartets were played on four sets of pipes of different sizes and pitch. The modern mouth-organ is the representative of the syrinx, although blown by means of a free reed.

SYRUP (O. Fr. *ysserop*, mod. *sirop*, Span. *xarope*, for *axarope*, Arab. *al*, the, and *sharab*, drink; cf. "Sherbet" and "Shrub"), the name given to a thick, viscid liquid, containing much dissolved (generally crystalline) matter, but showing little tendency to deposit crystals. The "syrup" employed for medicinal purposes consists of a concentrated or saturated solution of refined sugar in distilled water. The simple "syrup" of the British Pharmacopoeia is prepared by adding 1000 grams (or 5 lb) of refined sugar to 500 cubic centimetres (or two pints) of boiling distilled water, heating until it is dissolved and subsequently adding boiling distilled water until the weight of the whole is 1500 grams (or $7\frac{1}{2}$ lb). The specific gravity of the syrup should be 1·33. *Flavoured syrups* are made by adding flavouring matter to a simple syrup. For instance, *syrupus aromaticus* is prepared by adding certain quantities of orange and cinnamon water to simple syrup. Similarly, *medicated syrups* are prepared by adding medicaments to, or dissolving them in, the simple syrup. *Golden syrup* is the uncrystallizable fluid drained off in the process of obtaining refined crystallized sugar. *Treacle* and molasses are syrups obtained in the earlier stages of refining. Technically and scientifically the term syrup is also employed to denote viscid, generally residual, liquids, containing substances other than sugar in solution.

SYRYENIANS (also Sirianian, Syrjenian, Zyrenian, Zirianian, Zyrian and Zirian), a tribe belonging to the Permian division of the eastern Finns. They are said to number about 85,000 on the west side of the Urals in the governments of Perm, Vologda and Archangel, and there are also about 1000 on the Siberian side of the lower Ob. Their headquarters are at Ust-Ishma, at the junction of the Ishma and Pechora. Formerly they spread farther to the west. They are of moderate stature, blond, and grey-eyed, and more energetic and inclined to trade than most of the allied tribes. They were converted to Christianity about 1350 and their language was reduced to writing. They call themselves Komi and are not sharply distinguished from the tribes known as Permian, the languages being mutually intelligible. The archaeological remains in the governments of Perm and Vatyka called Chudish by Russians are probably Syryenian. A grammar of the language was published by Castrén, and linguistic and other notices of the tribe are contained in the *Journal de la société finno-ougrienne*, especially for 1903. (See FINNO-UGRIAN.)

SYSTYLE (Gr. σύν, together with, and στῦλος, a column), in architecture, a term meaning having columns rather thickly set—an intercolumniation to which two diameters are assigned.

SYZRAÑ, a town of Russia, in the government of Simbirsk, 156 m. E. of the town of Penza, and a short distance from the Volga. Pop. (1882), 24,500; (1900), 33,046. Syzrañ originated in a fort, erected in 1683, to protect the district from the Tatars and Circassians. Most of its inhabitants are engaged in gardening and tillage. In the large villages of the surrounding district various petty trades are carried on. The town has long been in repute for its tanneries and its manufactures of leather. Several flour-mills and other factories have recently sprung up. Much grain is exported; timber is brought from the upper Volga, and manufactured wares from Nizhniy Novgorod.

SYZYGY (Gr. συζυγία, a yoking together, from σύν, together, and root ζυγ-, yoke), in astronomy, either of the points at which the moon is most nearly in a line with the sun. The moon passes her syzygies, or is in a syzygy, at new and full moon.

[1] The Syriac versions made by him and his successors have unfortunately perished (see Wright, p. 213).

SZABADKA (Ger. *Maria-Theresiopel*), a town of Hungary, in the county of Bács-Bodrog, 109 m. S.S.E. of Budapest by rail. Pop. (1900), 81,464. It is situated in the great Hungarian plain between the Danube and the Theiss, and is the centre of an immense agricultural district. To the town belongs a large territory (369 sq. m.) of the adjoining Puszta Telecska, where large herds of cattle are reared. In this territory is situated Lake Palics, a favourite watering-place and summer resort.

SZABÓ VON SZENTMIKLÓS, JOZSEF (1822–1894), Hungarian geologist, was born at Kalocsa, on the 14th of March 1822. His first contribution to science was an essay on metallurgy, in which subject he had received special training. Afterwards he settled at Budapest and investigated the geology of the district, the results of which were published in a geological map (1858). In 1859 he joined the staff of the Austrian Geological Survey, as a volunteer member, and paid attention to the economic as well as to the purely scientific aspects of the work. He also arranged for surveys having special reference to agricultural geology to be undertaken by the Hungarian Geological Institute. In 1862 he became professor of geology and mineralogy in the university of Budapest. In later years he devoted himself largely to petrology, and published memoirs on the trachytes of Hungary and Transylvania; on a new method of determining the species of felspars in rocks, depending on fusibility and flame-coloration; on the geology and petrology of the district of Schemnitz; and on Santorin Island. He died at Budapest on the 12th of April 1894.

He was author of *Geologie mit besonderer Rücksicht auf die Petrographie, den Vulkanismus u. die Hydrographie* (1883).

SZALAY, LADISLAS (1813–1864), Hungarian statesman and historian, was born at Buda on the 18th of April 1813. After the completion of his studies, he became a member of the Hungarian parliament, and in 1848 he represented Hungary in the German national parliament at Frankfort. He took part in the revolution of 1848–49, and was obliged to seek refuge in Switzerland, where he wrote his history of Hungary. This important work, published at Budapest (1856–1860), extends to 1707. Szalay also wrote remarkable studies on Pitt, Fox, Mirabeau and other statesmen, and contributed very considerably to the codification of Magyar law. In later life he returned to Hungary, but he died at Salzburg on the 17th of July 1864.

See Alexander Flegler, *L. von Szalay* (Leipzig, 1866).

SZÉCHENYI, ISTVAN, Count (1791–1860), Hungarian statesman, the son of Ferencz Széchenyi and the countess Juliana Festetics, was born at Vienna on the 21st of September 1791. Very carefully educated at home till his seventeenth year, when he entered the army, he fought with distinction at the battle of Raab (June 14, 1809), and on the 19th of July brought about the subsequent junction of the two Austrian armies by conveying a message across the Danube to General J. G. Chasteler at the risk of his life. Equally memorable was his famous ride, through the enemy's lines on the night of the 16th-17th of October 1813, to convey to Blücher and Bernadotte the wishes of the two emperors that they should participate in the battle of Leipzig on the following day, at a given time and place. In May 1815 he was transferred to Italy, and at the battle of Tolentino scattered Murat's bodyguard by a dashing cavalry charge. From September 1815 to 1821 he visited France, England, Italy, Greece and the Levant, carefully studying the institutions of the countries through which he passed, and everywhere winning admirers and friends. A second—scientific—tour with his friend, Baron Miklos Wesselényi, taught him much about trade and industry, which knowledge he subsequently applied to his country's needs. In 1825, when he went to France in the suite of Prince Pàl Esterházy, to attend the coronation of Charles X., the canal du Midi especially attracted his attention and suggested to him the idea of regulating the rivers Danube and Theiss. At the Diet of 1825, when the motion for founding a Hungarian academy was made by Pál Nagy, who bitterly reproached the Magyar nobles for so long neglecting their mother-tongue, Széchenyi offered to contribute a whole year's income (60,000 florins) towards it. His example was followed by three other magnates who contributed between them 58,000 florins more. A commission was thereupon appointed to settle the details, and on the 18th of August the project received the royal assent. Another of his great projects was the opening up of the Danube for trade from Buda to the Black Sea. He satisfied himself of the practicability of the scheme by a personally conducted naval expedition from Pest to Constantinople. The Palatine Joseph was then won over, and on the 20th of June 1833 a Danube Navigation Committee was formed which completed its work in ten years. Széchenyi was also the first to start steamboats on the Theiss, the Danube and the lake of Balaton. It was now, too, that he published his famous work *Stadium*, suggesting a whole series of useful and indeed indispensable reforms (1833), which was followed by *Hunnia* (1834), which advocated the extension and beautifying of Budapest so as to make it the worthy capital of a future great power. His *A Few Words on Horse-racing*, a sport which he did so much to introduce and ennoble, appeared in 1839.

All this time Széchenyi had been following, with some anxiety, the political course of Kossuth. He sincerely believed that the exaggeration and exaltation of the popular editor of the *Pesti Hirlap* would cast the nation back into the old evil conditions from which it had only just been raised, mainly by Széchenyi's own extraordinary efforts, and in *Kelet népe*, which is also an autobiography, he prophetically hinted at an approaching revolution. "Trample on me without ceremony," he wrote to Kossuth on this occasion, "but for God's sake don't use the nimbus of your popularity to plunge Hungary into chaos." On this very point of reform the nation was already divided into two parties, though only the minority held with Széchenyi. But neither this fact nor the gradual loss of his popularity restrained Széchenyi, both in the Diet and at county meetings, from fulminating conscientiously against the extreme demands of Kossuth. His views at this period are expounded in the pamphlet *Politikai programm töredékek* ("Fragments of a Political Programme"). He held the portfolio of ways and communications in the first responsible Magyar administration (March 23, 1848) under Bátthyány, but his increasing apprehension of a revolution, with its inevitable corollaries of civil war and a rupture with the dynasty, finally affected his mind, and on the 5th of September he was removed to an asylum. Here he remained for many years, but recovered sufficiently to correspond with his friends and even to meditate writing fresh books. In 1859 he published the pamphlet *Ein Blick* in which he implored his countrymen to accept the Bach system as the best constitution attainable in the circumstances. The sudden death of his old friend Baron Samuel Jósika and the once more darkening political horizon led him, in a moment of despair, to take his own life (April 8, 1860). He richly deserved the epithet "the greatest of the Magyars" bestowed upon him by his political antagonist Kossuth.

Most of his numerous works on political and economical subjects have been translated into German. The best complete edition of his writings has been published, in nine volumes, by the Hungarian Academy (Pest, 1884–1896). See *Life of Széchenyi*, by Zsigmond Kemény (Hung.; Pest, 1870); Aurel Kecskeméthy, *The Last Years and Death of Count Széchenyi* (Hung.; Pest, 1866); Menyhert Lonyai, *Count Széchenyi and his Posthumous Writings* (Hung.; Budapest, 1875); Max Falk, "Der Graf Stephen Széchenyi und seine Zeit" (in the *Oesterreichische Revue*, Vienna, 1867); Antál Zichy, *Count Széchenyi as a Pedagogue* (Hung.; Budapest, 1876); Pál Gyulai, *Széchenyi as a Writer* (Hung.; Budapest, 1892); Antál Zichy, *Biographical Sketch of Count Stephen Széchenyi* (Hung.; 2 vols., Budapest, 1896–1897). (R. N. B.)

SZE-CH'UEN (Four Rivers), a western province of China, bounded N. by Kokonor, Kan-suh and Shen-si, E. by Hu-peh and Hu-nan, S. by Kwei-chow and Yun-nan, and W. by Tibet. Estimates of its population vary from 45,000,000 to 68,000,000; estimates of its area from 185,000 to 218,000 sq. m. It is considerably larger than any other province of China, Yun-nan, which comes next in size, covering less than 150,000 sq. m. Sze-ch'uen contains twelve prefectual cities, inclusive of Ch'êng-tu Fu, the provincial capital. The western portion forms part of the mountain-lands of Central Asia and much of it is over 10,000 ft. high, while heights of 16,000 to 19,000 ft. occur. The northern portion is also mountainous, but the east central part of Sze-ch'uen consists of a red sandstone table-land (see CHINA, § 1). Towards the north-east end of this plateau, commonly known as "the red basin," is Ch'ĕng-tu Fu (pop. 450,000–500,000), the provincial capital. The plain in which the city stands is about 70 m. long and 30 wide, and is noted for the density of its population (about 5,000,000), its wealth, and its splendid irrigation works.

The fauna includes bears, yaks, various kinds of antelope, monkeys and parrots. The flora includes magnificent yews, a great variety of bamboos, tallow, varnish, soap, and wax trees, rhododendrons and giant azaleas. The ethnological and commercial boundaries are sharply defined by the physical features. The mountain districts are poorly cultivated, and are inhabited by *Ijin* or barbarians, who are distinguished under the tribal names of Si-fan, Lo-lo and Man-tsze, and who maintain a semi-independence. Tibetans are also scattered over the western region and are numerous in the district of Pa-tang. The table-land is inhabited by Chinese, and is one of the most thriving and populous regions in the empire. These Chinese exhibit great diversity of type, due in part to immigration from other provinces in the 17th century—three fourths of the inhabitants having, it is said, been exterminated towards the close of the Ming dynasty.

Through the southern portion of Sze-ch'uen runs the Yangtsze-kiang, which is there navigable throughout the year, while the province is traversed by three large rivers, the Min-kiang, the Fu-sung-ho and the Kialing-kiang, all of which take their rise in the mountains on its north-west border, and empty into the Yangtsze-kiang at Su-chow Fu, Lu Chow and Chung-k'ing Fu respectively. A series of rapids disturb the waters of the Yangtsze-kiang between I-ch'ang and Chung-k'ing, a distance of about 500 m. According to the native authorities there are 13 big rapids and 72 smaller ones on these waters. In ordinary circumstances it takes about six weeks to traverse the distance. In 1898 Mr A. Little took a steamer, which had been built for the purpose, up the rapids, and since then one or more of these boats have ascended them. The province is intersected by numerous but difficult roads. The Ta-pei-lu, or great north road, leads from Ch'ĕng-tu Fu to Peking. From the same centre there branch roads to Chung-k'ing Fu, to Pao-ning Fu and to Ya-chow Fu, while another road connects Chung-k'ing Fu with Kwei-chow Fu on the Yangtsze-kiang and beyond with I-ch'ang Fu in Hu-peh. From Ya-chow Fu, again, start two important roads, one leading into Tibet by way of Yung-king, Ts'ing-k'i Hien, Ta-chien-lu, Li-tang, Pa-tang and Chiamdo, and the other to Western Yun-nan via Ts'ing-k'i Hien, Ning-yuen Fu, and Yen-yuen Hien to Ta-li Fu. From Ta-li Fu this road continues through Momein to Bhamo in Burma. Another road connects Pa-tang and Li-kiang Fu with Ta-li Fu, and yet another crosses the southernmost corner of the province connecting Tung-ch'uen Fu in Yun-nan with Ta-li Fu in the same province. In 1910 a loan of £6,000,000 was arranged for the construction of a railway from Hankow through the provinces of Hu-peh and Sze-ch'uen to Ch'eng-tu Fu.

The products of Sze-ch'uen include silk, tea, rice, sugar, hemp, vegetable wax, tobacco, timber and oranges. A larger quantity of silk is produced in eastern Sze-ch'uen than in any other province of the empire. Large quantities are exported to Shen-si, Shan-si, Kan-suh, Peking, Yun-nan, Tibet, Kwei-chow, Kwang-si, Hu-nan and Hu-peh.

Wax. White wax is another valuable article of the Sze-ch'uen trade. It is made exclusively in the department of Kia-ting Fu, the climate of which appears to favour the propagation of the disease among the insects which is said by the natives to be the cause of the plentiful secretion of wax. This belief is borne out by the fact, that in the districts where the insects breed only a small quantity of wax is produced, and experience has taught the natives the advantage of breeding the insects in one district and producing the wax in another. The region of Kien-chang in the south of the province has been found most suitable for breeding purposes, and it is there, therefore, on the insect trees, which are evergreens with large and pointed ovate leaves, that the breeding processes are carried on. At the end of April the producers start each with a load of the eggs of the insects for the district of Kia-ting Fu, a journey which on foot occupies about a fortnight. The road between the two districts is very mountainous, and as exposure to the heat of the sun would hatch the eggs too rapidly, the travellers journey only during the night. At Kia-ting Fu the eggs are eagerly bought up, and are at once put upon the wax tree. Baron von Richthofen thus describes the subsequent process:—

"When the egg balls are procured they are folded up, six or seven together in a bag of palm leaf. These bags are suspended on the twigs of the trees. This is all the human labour required. After a few days the insects commence coming out. They spread as a brownish film over the twigs, but do not touch the leaves. The Chinese describe them as having neither shape, nor head, nor eyes, nor feet. It is known that the insect is a species of coccus. Gradually, while the insect is growing, the surface of the twigs becomes encrustated with a white substance; this is the wax. No care whatever is required. The insect has no enemy, and is not even touched by ants. In the latter half of August the twigs are cut off and boiled in water, when the wax rises to the surface. It is then melted and poured into deep pans. It cools down to a translucent and highly crystalline substance."

Tobacco is grown very generally throughout the province, and is exported in large quantites to Si-fan, Tibet, Yun-nan, Hu-nan, and the export to Hankow alone is estimated at 6½ million lb annually. The best is grown in the district of P'i Hien; the next quality is said to come from Kin-t'ang Hien, and the third quality from Shih-fang Hien, all these districts being in the plain of Ch'ĕng-tu Fu. The habit, which is unknown in other provinces, of smoking the tobacco leaves rolled up in the shape of cigars obtains largely in Sze-ch'uen. Salt is also produced in Sze-ch'uen in large quantities from brine, which is raised from wells. Tsze-liu-tsing, in Tsze Chow, Wu-tung-kiao, hear Kia-ting Fu, Pao-ning Fu, and T'ung-ch'uen Fu, are the districts where the wells are most abundant. The brine is raised from the well with long bamboo tubes and bamboo ropes, and is then led to large pans for evaporation. In the district of Tsze-liu-tsing petroleum is struck at a depth of from 1800 to 2000 ft., and is used for evaporating the brine. Coal, iron and copper are found in many parts. The only coal worked is of an inferior quality, and the iron is smelted with wood alone. Ning-yuen Fu is the principal district from which the copper is produced. Wheat, barley, beans, rice, Indian corn, potatoes, &c., are among the other products of Sze-ch'uen.

Chung-K'ing Fu (pop. about 600,000) is the principal treaty port. It imports textiles, aniline dyes, metals, soap, petroleum &c., and exports silk, wax, tobacco, sugar, oil, musk, medicinal plants, &c. By the terms of the Mackay Treaty, signed at Shanghai in 1902, the port of Wan Hien (pop. 140,000), which is situated on the Yangtsze-kiang, 200 m. below Chung-K'ing Fu, was opened to trade in 1905. Both Protestant and Roman Catholic missions are at work in the province; the Protestants opening their first mission station, at Chung-K'ing, in 1877.

See L. Richard, *Comprehensive Geography of the Chinese Empire*, pp. 104–119 and the authorities there cited (Shanghai, 1908); also "The Province of Sze-ch'uen," in *The Chinese Empire* (M. Broomhall ed.; London, 1907); and Colonel C. C. Manifold, "Recent Exploration and Economic Development in Central and Western China," in *Geog. Journ.* (1904), vol. xxiii.

SZEGED (Ger., *Szegedin*), the capital of the county of Csongrád in Hungary, 118 m. S.E. of Budapest by rail. Pop. (1900), 100,270. It is situated on both banks of the Theiss just below the confluence of the Maros, and contains the inner town and four suburbs. It is the second town in Hungary as regards population, and since the disastrous inundation of the Theiss on the night of the 11th of March 1879, which almost completely destroyed it, Szeged has been rebuilt. It is now one of the handsomest towns of Hungary, and has several large squares, broad avenues, boulevards and many palatial buildings. It has also been encircled with a strong dam in order to protect it from floods. Among the principal buildings are a Franciscan convent, with a rich library and an interesting collection of antiquities and ecclesiastical objects; a Piarist and a Minorite convent; a handsome new town-hall; and a natural history and historical museum to which is attached a public library. Szeged is the chief seat of the manufacture of paprica, a kind of red pepper largely used in Hungary, and of a pastry called *tarhonya*; and has factories of soap, leather, boots, saw-mills and distilleries. Szeged is the centre of the commerce and industry of the great Hungarian Alföld, being an important railway junction and the principal port on the Theiss.

Since the 15th century Szeged has been one of the most prominent cities in Hungary. From 1541 till 1686 it was in possession of the Turks, who fortified it. It is also notorious for its many witchcraft trials. In 1848 it sent strong detachments to the national Hungarian army. In July 1849 the seat of the government was transferred hither for a short time.

SZÉKESFEHÉRVÁR (Ger., *Stuhlweissenburg*, Lat., *Alba Regalis* or *Alba Regia*), a town of Hungary, capital of the county of Fejér, 41 m. S.W. of Budapest by rail. Pop. (1900), 30,451. It is situated in a marshy plain and is a well-built and prosperous town. Székesfehérvár is the seat of a Roman Catholic bishopric, one of the oldest in the country, and was formerly a town of great importance, being the coronation and burial place of the Hungarian kings from the 10th to the 16th century. Amongst its principal buildings are the cathedral, the episcopal palace, several convents, of which the most noteworthy is the Jesuit convent, now a Cistercian secondary school with a handsome church, and the county hall. The town carries on a brisk trade in wine, fruit and horses, and is one of the principal centres of horse-breeding in Hungary. Székesfehérvár is one of the oldest towns of Hungary, in which St Stephen, the first king of Hungary, built a church, which served as the coronation church for the Hungarian kings. In the same church some fifteen kings were buried. In 1543 it fell into the hands of the Turks, under whom it remained until 1686. Before evacuating it, the Turks plundered the tombs of the kings, destroyed the old church and several other buildings, and burnt the archives. Several sarcophagi of the kings, and the foundations of the old church, have been found by excavation beneath the cathedral.

SZEKLERS, or SZEKELS (*Szekely*, Lat. *Siculi*), a Finno-Ugrian people of Transylvania, akin to the Magyars. They form a compact mass of rather more than 450,000, extending from near Kronstadt on the south to Maros-Vásárhely and Gyergó St Miklós on the north. Their origin is unknown and has been the subject of much learned debate. Their own ancient tradition affirms their descent from Attila's Huns. According to Procopius (*De bello gothico*, iv. 18) 3000 Huns entered Transylvania (*Erdeleu*, *i.e.* the Magyar *Erdély*) after their defeat "calling themselves, not Hungarians, but Zekul," and the Szeklers were the descendants of the Huns who stayed in Transylvania till the return of their kinsmen under Árpád; the anonymous scribe of King Béla speaks of them as "formerly Attila's folk." Von Rethy (*Ung. Rev.* vii. 812) suggests that they were originally a band of Black Ugrians who sought refuge in Transylvania after their defeat by the Pechenegs. Timon, however (*Magyar Alkotmány és Jogtörténet*, p. 75), points out that their language proves that their separation from the main Magyar stock must have taken place after the Magyar tongue had been fully developed (see also Hunfalvy, *Magyarország Ethnographiája*, 200). According to another theory they were Magyars transplanted by St Ladislaus to Transylvania in order to form a permanent frontier guard. Some such origin would, indeed, seem to be implied by the name Szekel, if this be derived, as Czetneki surmises ("Die Szeklerfrage," *Ung. Rev.* i. 411–428), from *szek*, seat, *i.e.* an administrative district (cf. the *Stuhl* of the Transylvanian Saxons); *Szekely* would thus mean simply "frontier-guards."

SZIGLIGETI, EDE (1814–1878), Hungarian dramatist, whose original name was József Szathmáry, was born at Nagyvárad-Olaszi, on the 8th of March 1814. His parents would have made him a priest; he wanted to be a great doctor; finally he entered the office of an engineer. But his heart was already devoted to the drama and, on the 15th of August 1834, despite the prohibition of his tyrannical father, he actually appeared upon the stage at Budapest. His father thereupon forbade him to bear his name in future, and the younger Szathmáry henceforth adopted instead the name of Ede Szigligeti, the hero of one of Sandor Kisfaludy's romances. He supported himself for the next few years precariously enough, earning as he did little more than twelve florins a month, but at the same time he sedulously devoted himself to the theatre and sketched several plays, which differed so completely from the "original" plays then in vogue (*The Played-out Trick* actually appeared upon the boards) that they attracted the attention of such connoisseurs as Vörösmarty and Bajza, who warmly encouraged the young writer. In 1840 the newly founded Hungarian Academy crowned his five-act drama *Rosa*, the title-rôle of which was brilliantly acted by Rosa Laborfalvy, the great actress, who subsequently married Maurus Jókai. Szigligeti was now a celebrity. In 1840 he was elected a member of the Academy and in 1845 a member of the Kisfaludy Society. He was now the leading Hungarian dramatist. Three of his plays were crowned by the National Theatre and sixteen by the Academy. His verdict on all dramatic subjects was for years regarded as final, and he was the mentor of all the rising young dramatists of the 'sixties. During the half-century of his dramatic career Szigligeti wrote no fewer than a hundred original pieces, all of them remarkable for the inexhaustible ingenuity of their plots, their up-to-date technique and the consummate skill with which the author used striking and unexpected effects to produce his *dénouement*. He wrote, perhaps, no work of genius, but he amused and enthralled the Magyar playgoing public for a generation and a half. Szigligeti's most successful tragedies were *Gritti* (1844), *Paul Beldi* (1856), *Light's Shadows* (1865), *Struensee* (1871), *Valeria* and *The Pretender* (1868). His tragedies, as a rule, lack pathos and sublimity. Much more remarkable are his comedies. He is a perfect master of the art of weaving complications, and he prefers to select his subjects from the daily life of the upper and upper-middle classes. The best of these comedies are *The Three Commands of Matrimony* (1850), *Tuneful Stevey* (1855), *Mamma* (1857), *The Reign of Woman* (1862), and especially the farce *Young Lilly* (1849). He also translated Goethe's *Egmont* and Shakespeare's *Richard III.*, and wrote a dramaturgical work entitled *The Drama and its Varieties*. A few of his plays have appeared in German.

See P. Rakodczay, *Edward Szigligeti's Life and Works* (Hung.; Pressburg, 1901); Pál Gyulai, *Memorial Speeches* (Hung.; Budapest, 1879 and 1890). (R. N. B.)

SZOMBATHELY (Ger., *Steinamanger*), the capital of the Hungarian county of Vas, 162 m. W. of Budapest by rail. Pop. (1900), 23,309. It is the seat of a Roman Catholic bishop, and possesses a beautiful cathedral (1797–1821) with two towers, 180 ft. high. Other buildings are the episcopal palace, to which is attached a museum of Roman antiquities, the county hall, the convent of the Dominicans and the seminary for Roman Catholic priests. Szombathely is an important railway and industrial centre, and has a state railway workshop, manufactories for agricultural machinery, foundries and steam mills.

About 5 m. south of Szombathely lies the small village of Jaák, with a Dominican convent from the 11th century, which has a remarkably beautiful church, one of the best specimens of Romanesque architecture in the country. About 16 m. by rail south of the town is Körmend (pop. 6171), with a beautiful castle belonging to Count Bathyanyi. About 16 m. by rail, west of Körmend is the small town of Szent Gotthard (pop., 2055, mostly Germans), with a Cistercian abbey, founded by King Béla III. in 1183, where General Montecucculi gained a decisive victory over the Turks in 1664.

Szombathely occupies the site of the Roman town *Sabaria* *Savaria*), which was the capital of Pannonia. Here in A.D. 193 Septimius Severus was proclaimed emperor by his legions. Many remains from the Roman period have been excavated, such as traces of an amphitheatre, a triumphal arch, the old fortifications, an aqueduct, &c. The remains are preserved partly in the museum at Budapest, and partly in the municipal museum. The bishopric was created in 1777.

T the last letter in the Semitic alphabet, where, however, its form in the earliest inscriptions is that of a St Andrew's Cross X. In both Greek and Latin, however, although the upright and cross stroke are frequently not exactly at right angles and the upright often projects beyond the cross stroke, the forms approach more nearly to the modern than to the Semitic shape. The name *Tāw* was taken over in the Greek *ταῦ*. The sound was that of the unvoiced dental stop. The English *t*, however, is not dental but alveolar, being pronounced, as *d* also, not by putting the tongue against the teeth but against their sockets. This difference is marked in the phonetic differentiation of the dental and the alveolar *t* by writing them respectively *t* and *ṭ*. The alveolar sound is frequent also in the languages of India, which possess both this and the dental sound. The Indian *ṭ*, however, is probably produced still farther from the teeth than is the English sound. In the middle of words when *t* precedes a palatal sound like *i* (*y*) which is not syllabic, it coalesces with it into the sound of *sh* as in *position*, *nation*, &c. The change to a sibilant in these cases took place in late Latin, but in Middle English the *i* following the *t* was still pronounced as a separate syllable. A later change is that which is seen in the pronunciation of *nature* as *neitṣ°*. This arises from the pronunciation of *u* as *yu*, and does not affect the English dialects which have not thus modified the *u* sound. Similar changes had taken place in some of the local dialects of Italy before the Christian era. At the end of words the English *t* is really aspirated, a breath being audible after the *t* in words like *bit*, *hit*, *pit*. This is the sound that in ancient Greek was represented by θ. In medieval and modern Greek, however, this has become the unvoiced sound represented in English by *th* in *thin*, *thick*, *pith*. Though represented in English by two symbols this is a single sound, which may be either interdental or, as frequently in English, produced "by keeping the tongue loosely behind the upper front teeth, so that the breath escapes partly between the tongue and the teeth, and partly, if the teeth are not very closely set, through the interstices between them" (Jespersen). In English *th* represents both the unvoiced sound þ as in *thin*, &c., and the voiced sound ð, which is found initially only in pronominal words like *this*, *that*, *there*, *then*, *those*, is commonest medially as in *father*, *bother*, *smother*, *either*, and is found also finally in words like *with* (the preposition), *both*. Early English used þ and ð indiscriminately for both voiced and unvoiced sounds, in Middle English ð disappeared and þ was gradually assimilated in form to *y*, which is often found for it in early printing. It is, however, to be regretted that English has not kept the old symbols for sounds which are very characteristic of the language. In modern Greek the ancient δ (*d*) has become the voiced spirant (ð), though it is still written δ. Hence to represent D, Greek has now to resort to the clumsy device of writing NT instead. (P. Gi.)

TAAFFE, EDUARD FRANZ JOSEPH VON, Count [11th Viscount Taaffe and Baron of Ballymote, in the peerage of Ireland] (1833–1895), Austrian statesman, was born at Vienna on 24th February 1833. He was the second son of Count Ludwig Patrick Taaffe (1791–1855), a distinguished public man who was minister of justice in 1848 and president of the court of appeal. As a child Taaffe was one of the chosen companions of the young archduke, afterwards emperor, Francis Joseph. In 1852 he entered the public service; in 1867 he was Statthalter of Upper Austria, and the emperor offered him the post of minister of the interior in Beust's administration. In June he became vice-president of the ministry, and at the end of the year he entered the first ministry of the newly organized Austrian portion of the monarchy. For the next three years he took a very important part in the confused political changes, and probably more than any other politician represented the wishes of the emperor. He had entered the ministry as a German Liberal, but he soon took an intermediate position between the Liberal majority of the Berger ministry and the party which desired a federalistic amendment of the constitution and which was strongly supported at court. From September 1868 to January 1870, after the retirement of Auersperg, he was president of the cabinet. In 1870 the government broke up on the question of the revision of the constitution: Taaffe with Potocki and Berger wished to make some concessions to the Federalists; the Liberal majority wished to preserve undiminished the authority of the Reichsrath. The two parties presented memoranda to the emperor, each defending their view, and offering their resignation: after some hesitation the emperor accepted the policy of the majority, and Taaffe with his friends resigned. The Liberals, however, failed to carry on the government, as the representatives of most of the territories refused to appear in the Reichsrath: they resigned, and in the month of April Potocki and Taaffe returned to office. The latter failed, however, in the attempt to come to some understanding with the Czechs, and in their turn had to make way for the Clerical and Federalist cabinet of Hohenwart. Taaffe now became Statthalter of Tirol, but once more on the breakdown of the Liberal government in 1879 he was called to office. At first he attempted to carry on the government without change of principles, but he soon found it necessary to come to an understanding with the Feudal and Federal parties, and he was responsible for the conduct of the negotiations which in the elections of this year gave a majority to the different groups of the National and Clerical opposition. In July he became minister president: at first he still continued to govern with the Liberals, but this was soon made impossible, and he was obliged to turn for support to the Conservatives. It was his great achievement that he persuaded the Czechs to abandon the policy of abstention and to take part in the parliament. It was on the support of them, the Poles, and the Clericals that his majority depended. His avowed intention was to unite the nationalities of Austria: Germans and Slavs were, as he said, equally integral parts of Austria; neither must be oppressed; both must unite to form an Austrian parliament. Notwithstanding the growing opposition of the German Liberals, who refused to accept the equality of the nationalities, he kept his position for thirteen years. Not a great creative statesman, he had singular capacity for managing men; a very poor orator, he had in private intercourse an urbanity and quickness of humour which showed his Irish ancestry. For the history of his administration see AUSTRIA-HUNGARY, *History* (Sec. II. "*Austria Proper*"). Beneath an apparent cynicism and frivolity Taaffe hid a strong feeling of patriotism to his country and loyalty to the emperor. It was no small service to both that for so long, during very critical years in European history, he maintained harmony between the two parts of the monarchy and preserved constitutional government in Austria. The necessities of the parliamentary situation compelled him sometimes to go farther in meeting the demands of the Conservatives and Czechs than he would probably have wished, but he was essentially an opportunist: in no way a party man, he recognized that the government must be carried on, and he cared little by the aid of what party the necessary majority was maintained. In 1893 he was defeated on a proposal for the revision of the franchise, and resigned. He retired into private life, and died two years later at his country residence, Ellerschau, in Bohemia, on 29th November 1895.

By the death of his elder brother Charles (1823–1873), a colonel in the Austrian army, Taaffe succeeded to the Austrian and Irish titles. He married in 1862 Countess Irma Tsaky, by whom he left four daughters and one son, Henry. The family history presents points of unusual interest. From the 13th century the Taaffes had been one of the leading families in the north of Ireland. In 1628 Sir John Taaffe was raised to the peerage as Baron Ballymote and Viscount Taaffe of Corven. He left fifteen children, of whom the eldest, Theobald, took a prominent part in the Civil War, accompanied Charles II. in exile, and on the Restoration was created earl of Carlingford. He was sent on missions to the duke of Lorraine and to the emperor, by which was established the connexion of his family with the house of Habsburg and Lorraine, which has continued to this day. His eldest son was killed in the Turkish wars. He was succeeded in the title by his second son Nicholas, who had served in the Spanish wars and was killed at the Boyne. The next brother, Francis, the third earl, was one of the most celebrated men of his time: he was brought up at Olmütz, at the imperial court, and in the service of Duke Charles of Lorraine, whose most intimate friend he became. He rose to the highest rank in the Austrian army, having greatly distinguished himself at the siege of Vienna and in the other Turkish campaigns, and was a member of the Order of the Golden Fleece. He was sent on many important diplomatic missions, and at the end of his life was chancellor and chief minister to the duke of Lorraine. Notwithstanding the Jacobite connexions of his family, his title to the earldom of Carlingford was confirmed by William III., and the attainder and forfeiture of the estates incurred by his brother was repealed. This favour he owed to his position at the court of the emperor, William's most important ally. On his death the title and estates went to his nephew Theobald, whose father had fallen during the siege of Derry, and who himself had served with distinction in the Austrian army. On his death the title of earl of Carlingford became extinct; both the Austrian and Irish estates as well as the Irish viscountcy went to a cousin Nicholas (1677–1769). Like so many of his family, he was brought up in Lorraine and passed into the Austrian army; he fought in the Silesian war, rose to be field-marshal, and was made a count of the Empire. His Irish estates were, however, claimed under the Act of 1703 by a Protestant heir: a lawsuit followed, which was ended by a compromise embodied in a private act of parliament, by which the estates were sold and one-third of the value given to him. With the money he acquired the castle of Ellerschau, in Bohemia; he had also inherited other property in the Austrian dominions. He was naturalized in Bohemia, and left on record that the reason for this step was that he did not wish his descendants to be exposed to the temptation of becoming Protestants so as to avoid the operation of the penal laws. His great-grandson was the father of the subject of this article. A Committee of Privileges of the House of Lords in 1860 recognized the right of the family to hold the Irish title.

See Wurzbach, *Biographisches Lexicon Oesterreichs*. *Memoirs of the Family of Taaffe* (Vienna, 1856), privately printed; article in the *Contemporary Review* (1893), by E. B. Lanin. The Prague *Politik* published in December 1904 contains some interesting correspondence collected from Taaffe's papers. (J. W. He.)

TAAL, a town of the province of Batangas, Luzon, Philippine Islands, on the Pansipit river, opposite Lemery, with which it is connected by a bridge, and about 50 m. S. of Manila. Pop. of the municipality (1903) 17,525. Taal is built, chiefly of stone, on the summit and terraced slopes of a hill overlooking the Gulf of Balayan into which the Pansipit river flows. It has a cool and healthy climate, is an important military station, and a port for coastwise vessels. Extensive agricultural lands in the vicinity produce rice, Indian corn, sugar-cane, pepper, cacao, and cotton, but the great coffee plantations which were formerly to be seen in its vicinity have been destroyed by insects. The inhabitants are also engaged in raising horses and cattle, in fishing, and in carrying on a considerable trade in cotton goods, sugar, coffee, &c. Taal is the only town in the Philippines where effective efforts have been made to exclude the Chinese. The hostility of the inhabitants toward them was such that none succeeded in establishing a residence here until the latter days of the revolution against the American government. The town was founded in 1754 after the destruction by Taal volcano of an old town of the same name on Lake Taal. The language is Tagalog.

TABACO, a town and port of entry of the province of Albay, Luzon, Philippine Islands, on Tabaco bay, about 20 m. N. of the town of Albay. Pop. (1903) 21,946. The men of Tabaco are largely engaged in the cultivation of hemp; the women in weaving cloth, baskets and mats. The town has a deep and well-protected harbour, and its shipping is extensive. The language is Bicol.

TABARD, a short coat, either sleeveless, or with short sleeves or shoulder pieces, emblazoned on the front and back with the arms of the sovereign, and worn, as their distinctive garment, by heralds and pursuivants. A similar garment with short sleeves or without sleeves was worn in the middle ages by knights over their armour, and was also emblazoned with their arms or worn plain. The name was also given in earlier days to a much humbler similar garment of rough frieze worn by peasants; the ploughman wears a "tabard" in the Prologue to the *Canterbury Tales*. Similarly at Queen's College, Oxford, the scholars on the foundation were called "tabarders," from the tabard, obviously not an emblazoned garment, which they wore. The word itself appears in Fr. *tabard* or *tabart*, &c., Ital. *tabarro*, Ger. *taphart*, Med. Lat. *tabbardus*, *tabardium*, &c. It is of doubtful origin, but has usually been connected with "tippet," "tapestry," from Lat. *tapete*, hangings, painted cloths; Gr. *τάπης*, carpet.

ṬABARĪ [Abū Ja'far Mahommed ibn Jarīr uṭ-Ṭabarī] (838–923), Arabian historian and theologian, was born at Amol in Tabaristan (south of the Caspian), and studied at Rei (Rai), Bagdad, and in Syria and Egypt. Cast upon his own resources after his father's death, he was reduced to great poverty until he was appointed tutor to the son of the vizier 'Ubaidallāh ibn Yaḥyā. He afterwards journeyed to Egypt, but soon returned to Bagdad, where he remained as a teacher of tradition and law until his death. His life was simple and dignified, and characterized by extreme diligence. He is said to have often refused valuable gifts. A Shāfi'ite in law, he claimed the right to criticize all schools, and ended by establishing a school of his own, in which, however, he incurred the violent wrath of the Hanbalites.

His works are not numerous, but two of them are very extensive. The one is the *Tārīkh ur-Rusul wal-Mulūk* (History of the Prophets and Kings), generally known as the *Annals* (cf. ARABIA, *Literature*, "History"). This is a history from the Creation to A.D. 915, and is renowned for its detail and accuracy. It has been published under the editorship of M. J. de Goeje in three series, comprising thirteen volumes, with two extra volumes containing indices, introduction and glossary (Leiden, 1879–1901). A Persian digest of this work, made in 963 by the Samanid vizier al-Bal'amī, has been translated into French by H. Zotenberg (vols. i.–iv., Paris, 1867–1874). A Turkish translation of this was published at Constantinople (1844). His second great work was the commentary on the Koran, which was marked by the same fullness of detail as the *Annals*. The size of the work and the independence of judgment in it seem to have prevented it from having a large circulation, but scholars such as Baghawī and Suyūṭī used it largely. It has been published in thirty vols. (with extra index volume) at Cairo, 1902–1903. An account of it, with brief extracts, has been given by O. Loth in the *Zeitschrift der Deutschen Morgenländischen Gesellschaft*, vol. xxxv. (1881), pp. 588–628. Persian and Turkish translations of the commentary exist in manuscript. A third great work was projected by Ṭabarī. This was to be on the traditions of the Companions, &c., of Mahomet. It was not, however, completed. Other smaller works are mentioned in the *Fihrist*, pp. 234–235. (G. W. T.)

TABARIN (Fr. *tabard*, Ital. *tabarrino*, a small cloak), the name assumed by Jean Salomon (*c.* 1584–1633), a Parisian street charlatan, who amused his audiences in the Place Dauphine by farcical dialogue with his partner Mondor (Phillippe Girard), with whom he reaped a golden harvest by the sale of quack medicines. A contemporary portrait shows him in the dress of a clown, but with a moustache and pointed beard, carrying a wooden sword and wearing a soft grey felt hat capable of assuming countless amusing shapes in his deft fingers. His regular evening antics were varied by more elaborate weekly performances in which others appeared, notably his wife. In these he took the part of a fat old fool, but his jokes, while usually coarse, were frequently clever, and his extemporized speeches were full of originality. He is said to have influenced both Molière and La Fontaine. The latter praises him, and he is also well spoken of by Boileau and Voltaire. He retired about 1628, and died on the 16th of August 1633. Numerous farces and dialogues, partly or wholly his, or in his *répertoire*, were credited to him, and long series of cheap leaflets purporting to be his complete works began to appear as early as 1622. Two rival editions, in two volumes and one volume respectively, were published as late as 1858. The word *Tabarin*, spelt with a capital, has been adopted into the French language to designate the comic performer of a street booth.

TABASCO, a state of Mexico, bounded N. by the Gulf of Mexico, E. by the state of Campeche and Guatemala, S. by Guatemala and Chiapas, and W. by Vera Cruz. Area 10,072 sq. m. Pop. (1900) 159,834. The surface is generally low and flat, largely covered with lagoons, watercourses and swamps. In the S. and S.E. there is an area belonging to the rough higher formation of Chiapas. Dense forests cover the whole region, and there are valuable fine woods and dye-woods. There are several large lagoons on the coast, two of which are called Sant' Ana and Tupilco bays. Two large rivers, the Grijalva and Usumacinta, traverse its territory. The Grijalva, also called Tabasco, the upper course of which is known as the Chiapas, has its most distant sources in western Guatemala and flows N.W. across Chiapas to the frontier of Oaxaca, thence N. to the frontier of Tabasco, and thence N.E. to the coast; it is navigable for 93 m. The Usumacinta likewise has its sources in western Guatemala. It forms the boundary between Guatemala and Chiapas until the frontier of Tabasco is reached, where its N.W. course turns to the N. and then N.W. to a junction with the Grijalva—the two rivers having a common outlet. The Usumacinta, including its head streams, is about 500 m. long; excluding them about 330 m. long; for about 270 m. it is navigable, for about 180 m. for large steamers. There are no railways and no good roads, and these rivers and the navigable channels of the Cuxcuchopa, Soledad, Cocohital, Tular, and Tortuguero, are the principal practical thoroughfares in the state. The capital is San Juan Bautista (pop., 1900, 10,548), formerly called Villa Hermosa, on the Grijalva river, about 70 m. above its mouth. The next most important town is Frontera (pop., 1895, 6794), a port 3 m. within the mouth of the Grijalva.

TABERNACLE (Lat. *tabernaculum*, a hut, tent), specifically the name given in the English Bible to the portable sanctuary which, according to the priestly sources of the Pentateuch, was erected by Moses in the wilderness as the place of worship of the Hebrew tribes (Exodus xxv. ff.).

(1) *The Tabernacle and its Furniture.*—The Tabernacle proper is represented as standing within a rectangular area, measuring 100 cubits by 50, approximately 150 feet by 75, which formed the centre of the camp in the wilderness. This area, termed the "court of the tabernacle," was fenced off from the rest of the encampment by a series of curtains suspended from 100 pillars standing at intervals of 5 cubits, and lay east and west with its entrance on the eastern side. Of the two squares, each measuring 50 cubits by 50, into which the court may be divided, the more easterly was that in which the worshippers assembled. In the centre of this square stood the altar of burnt-offering, a hollow chest of acacia wood overlaid with bronze. The tabernacle itself also stood east and west, with its entrance towards the east, on the edge of the second square. The essential part of the structure, to which everything else was subsidiary, was that termed in the original the *mishkān, i.e.* dwelling (Eng. Vers. tabernacle, but see Exod. xxv. 9, Rev. Vers. margin). It was formed of ten curtains, in two sets of five, of the finest linen with inwoven coloured figures of cherubim, the whole making an artistic covering measuring 40 cubits by 28. Instead of being suspended on poles after the manner of an ordinary tent, the curtains of the dwelling were spread over a series of open frames of acacia wood overlaid with gold, each 10 cubits in height by $1\frac{1}{2}$ in breadth.[1] These frames, 48 in all, were so arranged as to form the southern, western and northern sides of a rectangular structure, 30 cubits in length and 10 cubits in breadth and height. Over the frames, as has been said, were thrown the two sets of tapestry curtains above described, while the eastern end, forming the entrance, was closed by a special portière suspended from five pillars. The dwelling was divided into two parts by a second hanging, the "veil," 10 cubits from the western end. These two parts were termed respectively the holy place, and the most holy place or "holy of holies." Within the latter stood, in solitary majesty, the ark of God, in which were deposited the two stone tables of the decalogue or "testimony." On the ark lay a solid slab of the finest gold, the propitiatory or mercy-seat, from which rose the figures of two golden cherubim. The propitiatory with its over-arching cherubim formed the innermost shrine of the wilderness sanctuary, the earthly throne of the God of heaven.

The furniture of the holy place consisted of the table of shewbread, the altar of incense—both, like the ark, of acacia wood overlaid with gold—and the golden "candlestick," the latter in reality a seven-branched lamp-stand. As a protection the delicate and artistic curtains of the dwelling were covered by two similar sets of goats'-hair curtains, which together measured 44 cubits by 30; these, in their turn, were protected by a double covering, the one of rams' skins dyed red, the other made of the skins of a Red Sea mammal, probably the dugong (Exod. xxvi. 14).

(2) *The Religious Significance of the Tabernacle.*—The aim of the priestly school, to whom we owe the conception of the tabernacle as above described, was to provide a sanctuary and a ritual worthy of the higher conceptions of the Deity, which had grown up as the fruit of the discipline of the exile. The ideal relation of Jehovah (Yahweh) to the theocratic community of Israel had already been described by Ezekiel in the words "my dwelling shall be with them, and I will be their God, and they shall be my people" (xxxvii. 27). That this was the religious ideal in the mind of the author of Exodus xxv. ff. is evident from the characteristic name which he gives to the essential part of the tabernacle, the *dwelling* (see above, and cf. Exod. xxv. 8). All the arrangements of the camp and of the tabernacle are intended to secure the presence of a holy God in the midst of a holy people. The thought of the almost unapproachable holiness of the Deity underlies not only the gradation of the parts of the tabernacle—court, holy place and holy of holies being each marked by an ascending degree of sanctity—but also the careful gradation of the materials employed in its construction. In the proportion and symmetry, which are strongly marked features of the tabernacle, we may further trace the earnest endeavour to reflect the harmony and perfection of the Deity whose glory filled the dwelling (Exod. xl. 34).

(3) As regards the historicity of this elaborate sanctuary modern historical criticism has pronounced a negative judgment. This verdict is based not so much on the many difficulties presented by the narrative itself, or suggested by the unexpected wealth of material and artistic skill, as on the impossibility of reconciling the picture of the tabernacle and its worship, which is found in the middle books of the Pentateuch, with the religious history of Israel as reflected in the older historical books. There is absolutely no place for the tabernacle of the Priests' Code in the history of the worship of the Hebrews before the exile. It cannot be reconciled with the account of the historical "tent of meeting" (Auth. Vers. tabernacle of the congregation) of the oldest Pentateuch sources in any particular except the common designation, and in the later history of the ark, whether at Shiloh or at Jerusalem, the older records of Samuel and Kings are silent as to the tabernacle.

The sections of the Pentateuch devoted to the tabernacle and its worship, therefore, are not to be treated as history but as the expression of a religious ideal. Building on the traditions of the simple Mosaic "tent of meeting" (Exodus xxxiii. 7 ff. and elsewhere), and believing that the temple of Solomon was its replica on a larger scale and in more solid materials, the priestly idealists followed the example of Ezekiel, and elaborated an ideal sanctuary to serve as the model for the worship of the theocratic community of the future. "Let them make me a sanctuary, that I may dwell among them" (Exod. xxv. 8).

See "Tabernacle" in Hastings's *Dictionary of the Bible*, vol. iv., with which may be compared the corresponding articles in Cheyne and Black's *Encycl. Biblica* by Benzinger, and in the *Jewish Encyclopedia* by König. The views of the first-named article, summarised above, as to the framework of the Tabernacle, have been adopted and reinforced by A. H. M'Neile in his Commentary on *The Book of Exodus* (1908), pp. lxxiii. ff. (A. R. S. K.)

[1] For the philological and other arguments in favour of open frames in place of the traditional solid beams—the "boards" of the English version—as supports of the curtains, see the writer's article "Tabernacle" in Hastings's *Dict. of the Bible*, iv. 659 f., with illustrative diagrams.

TABERNACLE, as a general term in architecture, a species of niche or recess in which an image may be placed. In Norman work there are but few remains, and these generally over doorways. They are shallow and comparatively plain, and the figures are often only in low relief, and not detached statues. In Early English work they are deeper, and instead of simple arches there is often a canopy over the figure, which was placed on a small, low pedestal. Later in the style the heads of the tabernacles became cusped, either as trefoils or cinquefoils, and they are often placed in pairs side by side, or in ranges, as at Wells cathedral. Decorated tabernacles are still deeper and more ornamented, the heads are sometimes richly cusped and surmounted with crocketed gables, as at York, or with projecting canopies, very much like the arcade at Lichfield. In this case the under side of the canopy is carved to imitate groined ribs, and the figures stand either on high pedestals, or on corbels. Perpendicular tabernacles possess much the same features, but the work is generally more elaborate (see CORBEL, CANOPY, NICHE, &c.). The word tabernacle is also often used for the receptacle for relics, which was often made in the form of a small house or church (see SHRINE). The term "tabernacle work" is given, in architecture, to the richly sculptured tracery, similar to that employed on the upper part of a tabernacle, decorated with canopied niches which contain statues. The Eleanor crosses in England are enriched with tabernacle work over the niches, as also the chapels of Bishops Nicholas West (1461–1533), and John Alcock (1430–1500) in Ely cathedral, both dating from the beginning of the 16th century.

TABERNACLES, FEAST OF, the autumn festival of the Israelites, beginning on the 15th of Tishri and celebrated by residing for the seven succeeding days in rustic booths (Heb. *Sukkoth*, in the Vulgate *Tabernacula*, whence the English name of the feast). Among the Hebrews it was the third and chief of the three annual pilgrimage festivals connected respectively with the harvesting of the barley (Passover), of wheat (Pentecost), and of the vine (Tabernacles). Hence it is referred to as "the Feast" *par excellence* (Heb. *Heḥag*, cf. Arab. *Hajj*) even as late as 2 Chron. vii. 9. Being of the nature of a pilgrimage feast the booths were temporary erections for the accommodation of the pilgrims. But in early Jewish tradition, in both Yahvist and Elohist sources of the Pentateuch (Exod. xxxiv. 22, xxiii. 16) it is called simply the Harvest Feast (A.V. "Feast of Ingathering") and is to be observed "at the end of the year," *i.e.* of the agricultural year. In Deut. xvi. 13 seq., it is termed the Feast of Tabernacles and is to be kept seven days after the produce of the threshing-floor and winepress has been gathered in. In the Holiness Code (Lev. xxiii. 39) it is to be kept for seven days after the first, the first of which is to be "a sabbath," and the eighth "a sabbath" (possibly originally a lunar quarter-day): branches of four trees are to be taken. In the Priestly Code (Lev. xxiii. 33 seq.; Num. xxix. 12–38) the first and eighth day are to be days of holy assembly, and in the latter passage elaborate details are given of the sacrifices to be presented, including a series of bullocks, thirteen on the first day, twelve on the next, and so on down to seven on the seventh day. Only one is to be sacrificed on the concluding feast (Heb. *'Aẓereth*) of the eighth day.

The higher criticism sees, in these successive enactments of the various codes included in the Pentateuch (*q.v.*), a development in the character of the festival. At first held at any of the local shrines, such as Gilgal, Bethel, Shiloh, as well as Jerusalem, it was held at an indefinite date during the harvest in the fall of the year. Then with the concentration of the cultus at Jerusalem represented by Deuteronomy, the celebration was restricted to the Judean capital, and its duration fixed at seven days, though its date was still left indeterminate. This was fixed in the Priestly Code at the 15th of the seventh month, and an eighth day of solemn assembly added after the return from the exile.

Against this hypothetical reconstruction is the fact that Solomon appears to have selected the occasion of the feast for the dedication of the temple, and that it lasted, even in his time, seven days (1 Kings viii. 2, 65). Jeroboam arranged for a similar feast in the northern kingdom on the 15th day of the eighth month, "like unto the feast in Judah" (*ibid.* xii. 32). The determination of a fixed date must therefore have been much earlier than Deuteronomy or the alleged period of the Priestly Code. A pilgrimage feast must be fixed in date to ensure the simultaneous presence of the pilgrims. There are, besides, seeming references to the feast in the early prophets, as Hosea xii. 9, Amos v. 21, as well as in Isaiah ix. 2 (Heb.). The concluding feast does not seem to refer to tabernacles *per se*, but to be distinct from it, as is shown by the break in the descending series of the sacrifices of bullocks as given in Numbers. In Jewish practice the concluding feast is not held in booths, and Maimonides (*Moreh*, iii. 42) suggests that its object was to give opportunity for final proceedings in assembly halls.

The existence, therefore, of much variation in the practice of the festival in historic times is scarcely proved by the seeming variations of the enactments concerning it in the Pentateuch. It is possible, however, that there may have been differences of custom in the carrying out of the feast. In Neh. xiii. 15 the trees whose branches were used for making the booths appear to differ from those mentioned in Lev. xxiii. 40, though in Jewish tradition the latter passage was taken to refer to the *Lulab*, or a combination of twigs of willow and myrtle, with a palm branch, which, together with a citron, are held in the hand during processions in the synagogue. The Sadducees and Karaites did not carry these in their hand, but used them as decorations of the booths. In the second temple there was a water libation every morning of the festival, and on the evening of the first day the great golden candelabrum was lit up and the men danced a torch dance around it (Mishnah, *Sukkah*, v. 2–4). It is reported by Josephus that, when Alexander Jannaeus, in the year 95 B.C., was acting as high-priest in the temple on the Feast of Tabernacles, instead of pouring the water libation on the altar, according to the Pharisaic custom, he poured it at his feet, giving rise to a riot in which 6000 men are said to have lost their lives (*Ant.* xii., xiii., 5; Talmud, *Sukkah*, 48 b).

The festival is certainly an agricultural one, and is so termed in the Pentateuch. Whether it was derived from the Canaanites, who had similar festivals (Judges xxix. 27), is uncertain. All nations have similar harvest homes, especially with reference to the vintage feasts; as, for instance, the Athenian Oschophoria. The Syrians celebrated every three years a "Booth Festival." At the Hindu Festival of *Dasara*, which lasted nine days from the new moon of October, tents made of canvas or booths made of branches were erected in front of the temples. The Spartans had a nine days' festival termed Carnea, during which they dwelt in pavilions and tents in memory of their old camp life (Athenaeus, iv. 19). The Feast of Tabernacles is one of the few Jewish festivals described in classical writers. Plutarch (*Symposium* iv., vi. 2) compares Tabernacles with the Bacchic rites. It was pre-eminently the period of exultation in ancient Jewish rite, and the Mishnah declares that "He who has not seen the joy of the libations of Tabernacles has never in his life witnessed joy." So much importance was attributed to this festival that it was chosen as the occasion on which the Law should be recited during the sabbatical year (Deut. xxxi. 9–12), and the Messianic vision of Zechariah xiv. 16 sees the remnant of all the nations coming up to Jerusalem to worship the Lord of Hosts, and to keep the Feast of Tabernacles.

In later Jewish custom the one-year cycle of reading of sections from the Pentateuch ends on the concluding day of Tabernacles, which is therefore known as the Rejoicing of the Law (*Simḥat Torah*). The custom of dwelling, for part of the day at least, in booths, is still kept up by orthodox Jews, who have temporary huts covered with branches erected in their courtyards, and those who are not in possession of a house with a backyard often go to pathetic extremes in order to fulfil the law by making holes in roofs, across which branches are placed. (J. JA.)

TABLE (Lat. *tabula*), a flat, oblong slab supported upon legs or pillars; originally anything flat.[1] As one of the few indispensable pieces of domestic furniture, the table is of great antiquity. It was known, in a small and rudimentary form, to the Egyptians, who used wood for its construction; the Assyrians certainly employed metal and possibly other materials in its manufacture. Grecian tables were also often of metal, with three or four legs and of considerable variety of form; they were small and low. By Roman times the table had apparently become somewhat more common. The favourite form was the tripod, but one and four legs were also used. Already the shape varied considerably, and in addition to wood, there were tables of marble, ivory, bronze and the precious metals. The more costly examples were carved, inlaid or otherwise ornamented; cedar and the finely marked or grained woods generally were much sought after. As in Greece the tables were low; they were intended for reclining, rather than sitting; their legs were those of wild beasts, or were formed of sphinxes, termini and other figures. Some of those which remain are of extreme grace and most delicate workmanship; to them the Empire style is enormously indebted. In antiquity tables of any kind can only have been the appanage of the rich. In the early middle ages, although there was variety of form—the circular, semicircular, oval and oblong were all in use—tables appear, save in rare instances, to have been portable and supported upon trestles fixed or folding, which were cleared out of the way at the end of a meal. The custom of serving dinner at several small tables, which is often supposed to be a very modern refinement, was certainly followed in the French châteaux, and probably also in the English castles, as early as the 13th century. For persons of high degree, fixed tables were reserved. Even at a period when domestic furniture was of a very primitive character and few modern conveniences had been evolved, costly tables were by no means unknown—some dim traditions of Rome's refinements must necessarily have filtered through the centuries. Thus Charlemagne possessed three tables of silver and one of gold—no doubt they were of wood covered with plates of the precious metals. Before the 16th century the number of tables properly so called was small; hence very few of earlier date than the middle of that century have come down to us. In the chapter-house of Salisbury cathedral is a restored 13th-century example which stands practically alone. In point of age it is most nearly approached by the famous pair of trestle tables in the great hall at Penshurst.

When the table became a fixed and permanent piece of furniture the word "board," which had long connoted it, fell into disuse save in an allusive sense, and its place was taken by such phrases as "joyned table" and "framed table"—that is, jointed or framed together by a joiner; sometimes people spoke of a "standing" or "dormant" table. They were most frequently oblong, some two feet or two feet six inches wide, and the guests sat with their backs to the wall, the other side of the table being left free for service. Sometimes they were used as side-tables, or furnished with a cupboard beneath the board; they were supported on quadrangular legs or massive ends and feet full of Gothic feeling, and were several inches higher than the dining-table of the 20th century. Heavy stretchers or foot-rails were fixed close to the floor—for the avoidance, no doubt, of draughts. Oak was the usual material, but elm, cherry and other woods were sometimes used. Soon the legs became bulbous, and were gadrooned or otherwise ornamented, and the frame began to be carved. The introduction, before the 16th century closed, of the "drawing table" marked the rapidity with which this piece of furniture was developed. This was the forerunner of the "extending dining-table." Of the three leaves of which these tables were composed two were below the other; they drew out and were supported by brackets, while the slab proper dropped to the same level. Somewhat later legs became excessively bulbous; this ugly form gave place soon after the middle of the 17th century to baluster-shaped legs. Hitherto tables had, generally speaking, been large and massive—little in the nature of what is now called the "occasional table" seems to have been provided until some years after the Restoration. About that time small tables of varying sizes and shapes, but still of substantial weight, began to be made; many of them were flap-tables, which took up little room when they were not in use. These, however, had been known at an earlier date. Charles II. had not long been on the throne when the idea of the flap-table was amplified in a peculiarly graceful fashion. Two flaps were provided instead of one, the result being the rather large oval table of the "gate-leg" variety that has remained in use ever since, in which the open "gate" supports the flap. Towards the end of the reign tables began to have the graceful twisted legs joined to the flat serpentine stretchers, which produced, almost for the first time in English furniture, a sense of lightness and gaiety. The walnut tables of the end of the Stuart period were often inlaid with marquetry of great excellence. The number and variety of the tables in well-to-do households were now increasing rapidly, and the console-table was imported from the Continent contemporaneously with the common use of the mahogany side-table.

As mahogany came into general use, about the beginning of the second quarter of the 18th century, an enormous number of card-tables were made with plain or cabriole legs and spade or claw and ball feet, often with lions' heads carved upon the knees; the top folded up to half its size when open. The Chippendale school introduced small tables with carved openwork "galleries" round the edges (to protect china and other small objects), and clustered legs; Gothic forms and Chinese frets were for a time fashionable. Later in this century, so prolific in new forms of furniture, tables were frequently made of rosewood and satinwood; side-tables, often highly elaborate, adorned with swags and festoons and other classical motives, supported by termini or richly carved legs, were gilded and topped with marble slabs or inlaid wood. The Pembroke table, of oblong form, with two semi-circular or oblong leaves, with edgings of marquetry, was a characteristic feature of late 18th-century English furniture, and still retains its popularity. Then came the Empire period; the taper was replaced by the round leg, rosewood grew commoner, and brass mountings the rule. For illustrations see FURNITURE.

[1] For mathematical tables see next article. This use of the word comes from the analogy of the laying out of objects on an ordinary table.

TABLE, MATHEMATICAL. In any table the results tabulated are termed the "tabular results" or "respondents," and the corresponding numbers by which the table is entered are termed the "arguments." A table is said to be of single or double entry according as there are one or two arguments. For example, a table of logarithms is a table of single entry, the numbers being the arguments and the logarithms the tabular results; an ordinary multiplication table is a table of double entry, giving xy as tabular result for x and y as arguments. The intrinsic value of a table may be estimated by the actual amount of time saved by consulting it; for example, a table of square roots to ten decimals is more valuable than a table of squares, as the extraction of the root would occupy more time than the multiplication of the number by itself. The value of a table does not depend upon the difficulty of calculating it; for, once made, it is made for ever, and as far as the user is concerned the amount of labour devoted to its original construction is immaterial. In some tables the labour required in the construction is the same as if all the tabular results had been calculated separately; but in the majority of instances a table can be formed by expeditious methods which are inapplicable to the calculation of an individual result. This is the case with tables of a continuous quantity, which may frequently be constructed by differences. The most striking instance perhaps is afforded by a factor table or a table of primes; for, if it is required to determine whether a given number is prime or not, the only universally available method (in the absence of tables) is to divide it by every prime less than its square root or until one is found that divides it without remainder. But to form a table of prime numbers the process is theoretically simple and rapid, for we have only to range all the numbers in a line and strike out every second number beginning from 2, every third beginning from 3, and so on, those that remain being primes. Even when the tabular results are constructed separately, the method of differences or other methods connecting together different tabular results may afford valuable verifications. By having recourse to tables not only does the computer save time and labour, but he also obtains the certainty of accuracy.

The invention of logarithms in 1614, followed immediately by the calculation of logarithmic tables, revolutionized all the methods of calculation; and the original work performed by Henry Briggs and Adrian Vlacq in calculating logarithms in the early part of the 17th century has in effect formed a portion of every arithmetical operation that has since been carried out by means of logarithms. And not only has an incredible amount of labour been saved,[1] but a vast number of calculations and researches have been rendered practicable which otherwise would have been beyond human reach. The mathematical process that underlies the tabular method of obtaining a result may be indirect and complicated; for example, the logarithmic method would be quite unsuitable for the multiplication of two numbers if the logarithms had to be calculated specially for the purpose and were not already tabulated for use. The arrangement of a table on the page and all typographical details—such as the shape of the figures, their spacing, the thickness and placing of the rules, the colour and quality of the paper, &c.—are of the highest importance, as the computer has to spend hours with his eyes fixed upon the book; and the efforts of eye and brain required in finding the right numbers amidst a mass of figures on a page and in taking them out accurately, when the computer is tired as well as when he is fresh, are far more trying than the mechanical action of simple reading. Moreover, the trouble required by the computer to *learn* the use of a table need scarcely be considered; the important matter is the time and labour saved by it after he *has* learned its use.

In the following descriptions of tables an attempt is made to give an account of all those that a computer of the present day is likely to use in carrying out arithmetical calculations. Tables relating to ordinary arithmetical operations are first described, and afterwards an account is given of the most useful and least technical of the more strictly mathematical tables, such as factorials, gamma functions, integrals, Bessel's functions, &c. Nearly all modern tables are stereotyped, and in giving their titles the accompanying date is either that of the original stereotyping or of the *tirage* in question. In tables that have passed through many editions the date given is that of the edition described. A much fuller account of general tables published previously to 1872, by the present writer, is contained in the British Association *Report* for 1873, pp. 1–175.

Tables of Divisors (Factor Tables) and Tables of Primes.—The existing factor tables extend to 10,000,000. In 1811 L. Chernac published at Deventer his *Cribrum arithmeticum*, which gives all the prime divisors of every number not divisible by 2, 3, or 5 up to 1,020,000. In 1814–1817 J. C. Burckhardt published at Paris his *Tables des diviseurs*, giving the least divisor of every number not divisible by 2, 3, or 5 up to 3,036,000. The second million was issued in 1814, the third in 1816, and the first in 1817. The corresponding tables for the seventh, eighth, and ninth millions were calculated by Z. Dase and issued at Hamburg in 1862, 1863, and 1865. Dase died suddenly in 1861 during the progress of the work, and it was completed by H. Rosenberg. Dase's calculation was performed at the instigation of Gauss, and he began at 6,000,000 because the Berlin Academy was in possession of a manuscript presented by Crelle extending Burckhardt's tables from 3,000,000 to 6,000,000. This manuscript was found on examination to be so inaccurate that the publication was not desirable, and accordingly the three intervening millions were calculated and published by James Glaisher, the *Factor Table for the Fourth Million* appearing at London in 1879, and those for the fifth and sixth millions in 1880 and 1883 respectively (all three millions stereotyped). The tenth million, though calculated by Dase and Rosenberg, has not been published. The nine quarto volumes (*Tables des diviseurs*, Paris, 1814–1817; *Factor Tables*, London, 1879–1883; *Factoren-Tafeln*, Hamburg, 1862–1865) thus form one uniform table, giving the least divisor of every number not divisible by 2, 3, or 5, from unity to nine millions. The arrangement of the results on the page, which is due to Burckhardt, is admirable for its clearness and condensation, the least factors for 9000 numbers being given on each page. The tabular portion of each million occupies 112 pages. The first three millions were issued separately, and also bound in one volume, but the other six millions are all separate. Burckhardt began the publication of his tables with the second million instead of the first, as Chernac's factor table for the first million was already in existence. Burckhardt's first million does not supersede Chernac's, as the latter gives all the prime divisors of numbers not divisible by 2, 3, or 5 up to 1,020,000. It occupies 1020 pages, and Burckhardt found it very accurate; he detected only thirty-eight errors, of which nine were due to the author, the remaining twenty-nine having been caused by the slipping of type in the printing. The errata thus discovered are given in Burckhardt's first million. Other errata are contained in Allan Cunningham's paper referred to below.

Burckhardt gives but a very brief account of the method by which he constructed his table; and the introduction to Dase's millions merely consists of Gauss's letter suggesting their construction. The Introduction to the *Fourth Million* (pp. 52) contains a full account of the method of construction and a history of factor tables, with a bibliography of writings on the subject. The Introduction (pp. 103) to the *Sixth Million* contains an enumeration of primes and a great number of tables relating to the distribution of primes in the whole nine millions, portions of which had been published in the *Cambridge Philosophical Proceedings* and elsewhere. A complete list of errors in the nine millions was published by J. P. Gram (*Acta mathematica*, 1893, 17, p. 310). These errors, 141 in number, and which affect principally the second, third, eighth, and ninth millions, should be carefully corrected in all the tables. In 1909 the Carnegie Institution of Washington published a factor table by Prof. D. N. Lehmer which gives the least factor of all numbers not divisible by 2, 3, 5, or 7, up to ten millions. This table, which covers a range of 21,000 numbers on a single page, was reproduced by photography from a typewritten copy of the author's original manuscript. The introduction contains a list of errata in the nine millions previously published, completely confirming Gram's list.

The factor tables which have just been described greatly exceed both in extent and accuracy any others of the same kind, the largest of which only reaches 408,000. This is the limit of Anton Felkel's *Tafel aller einfachen Factoren* (Vienna, 1776), a remarkable and extremely rare book,[2] nearly all the copies having been destroyed. Georg Vega (*Tabulae*, 1797) gave a table showing all the divisors of numbers not divisible by 2, 3, or 5 up to 102,000, followed by a list of primes from 102,000 to 400,313. In the earlier editions of this work there are several errors in the list, but these are no doubt corrected in J. A. Hülsse's edition (1840). J. Salomon (Vienna, 1827) gives the least divisor of all numbers not divisible by 2, 3, or 5, up to 102,011, and B. Goldberg (*Primzahlen und Factoren-Tafeln*, Leipzig, 1862) gives all factors of numbers not divisible by 2, 3, or 5 up to 251,650. H. G. Köhler (*Logarithmisch-trigonometrisches Handbuch*, 1848 and subsequent editions) gives all factors of numbers not prime or divisible by 2, 3, 5, or 11 up to 21,525. Peter Barlow (*Tables*, 1814) and F. Schaller (*Primzahlen-Tafel*, Weimar, 1855) give all factors of *all* numbers up to 10,000. Barlow's work also contains a list of primes up to 100,103. Both the factor table and the list of primes are omitted in the stereotyped (1840) reprint. Full lists of errata in Chernac (1811), Barlow (1814), Hülsse's Vega (1840), Köhler (1848), Schaller (1855), and Goldberg (1862) are contained in a paper by Allan Cunningham (*Mess. of Math.*, 1904, 34, p. 24; 1905, 35, p. 24). V. A. Le Besgue (*Tables diverses pour la décomposition des nombres*, Paris, 1864) gives in a table of twenty pages, the least factor of numbers not divisible by 2, 3, or 5 up to 115,500. In Rees's *Cyclopaedia* (1819), article "Prime Numbers," there is a list of primes to 217,219 arranged in decades. The *Fourth Million* (1879) contains a list of primes up to 30,341. The fourth edition of the *Logarithmic Tables* (London, and Ithaca, N.Y., 1893) of G. W. Jones of Cornell University contains a table of all the factors of numbers not divisible by 2 or 5 up to 20,000. In the case of primes the ten-place logarithm is given. This table does not occur in the third edition (Ithaca, N.Y., 1891). On the first page of the *Second Million* Burckhardt gives the first nine multiples of the primes to 1423; and a smaller table of the same kind, extending only to 313, occurs in Lambert's *Supplementa* (1798). Several papers contain lists of high primes (*i.e.* beyond the range of the

[1] Referring to factor tables, J. H. Lambert wrote (*Supplementa tabularum*, 1798, p. xv.): "Universalis finis talium tabularum est ut semel pro semper computetur quod saepius de novo computandum foret, et ut pro omni casu computetur quod in futurum pro quovis casu computatum desiderabitur." This applies to all tables.

[2] For information about it, see a paper on "Factor Tables," in *Camb. Phil. Proc.* (1878), iii. 99–138, or the Introduction to the *Fourth Million*.

factor tables). Among these may be mentioned two, by Allan Cunningham and H. J. Woodall jointly, in the *Mess. of Math.*, 1902, 31, p. 165; 1905, 34, p. 72. See also the papers on factorizations of high numbers referred to under *Tables relating to the Theory of Numbers*. The Vienna Academy possesses the manuscript of an immense factor table extending to 100,000,000, constructed many years ago by J. P. Kulik (1793–1863) (see *Ency. math. Wiss.*, 1900–1904, i. 952, and Lehmer's *Factor Table*, p. ix.).

Multiplication Tables.—A multiplication table is usually of double entry, the two arguments being the two factors; when so arranged it is frequently called a Pythagorean table. The largest and most useful work is A. L. Crelle's *Rechentafeln* (Bremiker's edition, 1857, stereotyped; many subsequent editions with German, French, and English title-pages), which gives in one volume all the products up to 1000×1000, so arranged that all the multiples of any one number appear on the same page. The original edition was published in 1820 and consisted of two thick octavo volumes. The second (stereotyped) edition is a convenient folio volume of 450 pages.[1] In 1908 an entirely new edition, edited by O. Seeliger, was published in which the multiples of 10, 20, ..., 990 (omitted in previous editions) are included. This adds 50 pages to the volume, but removes what has been a great drawback to the use of the tables. Other improvements are that the tables are divided off horizontally and vertically by lines and spaces, and that, for calculations in which the last two figures are rejected, a mark has been placed to show when the last figure retained should be increased. Two other tables of the same extent (1000×1000), but more condensed in arrangement, are H. C. Schmidt's *Zahlenbuch* (Aschersleben, 1896), and A. Henselin's *Rechentafel* (Berlin, 1897). An anonymous table, published at Oldenburg in 1860, gives products up to 500×509, and M. Cordier, *Le Multiplicateur de trois cents carrés* (Paris, 1872), gives a multiplication table to 300×300 (intended for commercial use). In both these works the product is printed in full. The four following tables are for the multiplication of a number by a single digit. (1) A. L. Crelle, *Erleichterungstafel für jeden, der zu rechnen hat* (Berlin, 1836), a work extending to 1000 pages, gives the product of a number of seven figures by a single digit, by means of a double operation of entry. Each page is divided into two tables: for example, to multiply 9382477 by 7 we turn to page 825, and enter the right-hand table at line 77, column 7, where we find 77339; we then enter the left-hand table on the same page at line 93, column 7, and find 656, so that the product required is 65677339. (2) C. A. Bretschneider, *Produktentafel* (Hamburg and Gotha, 1841), is somewhat similar to Crelle's table, but smaller, the number of figures in the multiplicand being five instead of seven. (3) In S. L. Laundy, *A Table of Products* (London, 1865), the product of any five-figure number by a single digit is given by a double arrangement. The extent of the table is the same as that of Bretschneider's, as also is the principle, but the arrangement is different, Laundy's table occupying only 10 pages and Bretschneider's 99 pages. (4) G. Diakow's *Multiplikations-Tabelle* (St Petersburg, 1897) is of the same extent as Bretschneider's table but occupies 1000 pages. Among tables extending to 100×1000 (*i.e.* giving the products of two figures by three) may be mentioned C. A. Müller's *Multiplications-Tabellen* (Karlsruhe, 1891). The tables of L. Zimmermann (*Rechentafeln*, Liebenwerda, 1896) and J. Riem (*Rechentabellen für Multiplication*, Basel, 1897) extend to 100×10,000. In a folio volume of 500 pages J. Peters (*Rechentafeln für Multiplikation und Division mit ein- bis vierstelligen Zahlen*, Berlin, 1909) gives products of four figures by two. The entry is by the last three figures of the multiplicand, and there are 2000 products on each page. Among earlier tables, the interest of which is mainly historical, mention may be made of C. Hutton's *Table of Products and Powers of Numbers* (London, 1781), which contains a table up to 100×1000, and J. P. Gruson's *Grosses Einmaleins von Eins bis Hunderttausend* (Berlin, 1799)—a table of products up to 9×10,000. The author's intention was to extend it to 100,000, but only the first part was published. In this book there is no condensation or double arrangement; the pages are very large, each containing 125 lines.

Quarter-Squares.—Multiplication may be performed by means of a table of single entry in the manner indicated by the formula—

$$ab=\tfrac{1}{4}(a+b)^2-\tfrac{1}{4}(a-b)^2.$$

Thus with a table of quarter-squares we can multiply together any two numbers by subtracting the quarter-square of their difference from the quarter-square of their sum. The largest table of quarter-squares is J. Blater's *Table of Quarter-Squares of all whole numbers from 1 to 200,000* (London, 1888),[2] which gives quarter-squares of every number up to 200,000 and thus yields directly the product of any two five-figure numbers. This fine table is well printed and arranged. Previous to its publication the largest table was S. L. Laundy's *Table of Quarter-Squares of all numbers up to* 100,000 (London, 1856), which is of only half the extent, and therefore is only directly available when the sum of the two numbers to be multiplied does not exceed 100,000.

Smaller works are J. J. Centnerschwer, *Neuerfundene Multiplications- und Quadrat-Tafeln* (Berlin, 1825), which extends to 20,000, and J. M. Merpaut, *Tables arithmonomiques* (Vannes, 1832), which extends to 40,000. In Merpaut's work the quarter-square is termed the "arithmone." L. J. Ludolf, who published in 1690 a table of squares to 100,000 (see next paragraph), explains in his introduction how his table may be used to effect multiplications by means of the above formula; but the earliest book on quarter-squares is A. Voisin, *Tables des multiplications, ou logarithmes des nombres entiers depuis* 1 *jusqu'à* 20,000 (Paris, 1817). By a logarithm Voisin means a quarter-square, *i.e.* he calls a a root and $\frac{1}{4}a^2$ its logarithm. On the subject of quarter-squares, &c., see *Phil. Mag.* [v.] 6, p. 331.

Squares, Cubes, &c., and Square Roots and Cube Roots.—The most convenient table for general use is P. Barlow's *Tables* (Useful Knowledge Society, London, from the stereotyped plates of 1840), which gives squares, cubes, square roots, cube roots, and reciprocals to 10,000. These tables also occur in the original edition of 1814. The largest table of squares and cubes is J. P. Kulik, *Tafeln der Quadrat- und Kubik-Zahlen* (Leipzig, 1848), which gives both as far as 100,000. Blater's table of quarter-squares already mentioned gives squares of numbers up to 100,000 by dividing the number by 2; and up to 200,000 by multiplying the tabular result by 4. Two early tables give squares as far as 100,000, viz. Maginus, *Tabula tetragonica* (Venice, 1592), and Ludolf, *Tetragonometria tabularia* (Amsterdam, 1690); G. A. Jahn, *Tafel der Quadrat- und Kubikwurzeln* (Leipzig, 1839), gives squares to 27,000, cubes to 24,000, and square and cube roots to 25,500, at first to fourteen decimals and above 1010 to five. E. Gélin (*Recueil de tables numériques*, Huy, 1894) gives square roots (to 15 places) and cube roots (to 10 places) of numbers up to 100. C. Hutton, *Tables of Products and Powers of Numbers* (London, 1781), gives squares up to 25,400, cubes to 10,000, and the first ten powers of the first hundred numbers. P. Barlow, *Mathematical Tables* (original edition, 1814), gives the first ten powers of the first hundred numbers. The first nine or ten powers are given in Vega, *Tabulae* (1797), and in Hülsse's edition of the same (1840), in Köhler, *Handbuch* (1848), and in other collections. C. F. Faà de Bruno, *Calcul des erreurs* (Paris, 1869), and J. H. T. Müller, *Vierstellige Logarithmen* (1844), give squares for use in connexion with the method of least squares. Four-place tables of squares are frequently given in five- and four-figure collections of tables. Small tables often occur in books intended for engineers and practical men. S. M. Drach (*Messenger of Math.*, 1878, 7, p. 87) has given to 33 places the cube roots (and the cube roots of the squares) of primes up to 127. Small tables of powers of 2, 3, 5, 7 occur in various collections. In Vega's *Tabulae* (1797, and the subsequent editions, including Hülsse's) the powers of 2, 3, 5 as far as the 45th, 36th, and 27th respectively are given; they also occur in Köhler's *Handbuch* (1848). The first 25 powers of 2, 3, 5, 7 are given in Salomon, *Logarithmische Tafeln* (1827). W. Shanks, *Rectification of the Circle* (1853), gives every 12th power of 2 up to 2^{721}. A very valuable paper ("Power-tables, Errata") published by Allan Cunningham in the *Messenger of Math.*, 1906, 35, p. 13, contains the results of a careful examination of 27 tables containing powers higher than the cube, with lists of errata found in each. Before using any power table this list should be consulted, not only in order to correct the errata, but for the sake of references and general information in regard to such tables. In an appendix (p. 23) Cunningham gives errata in the tables of squares and cubes of Barlow (1814), Jahn (1839), and Kulik (1848).

Triangular Numbers.—E. de Joncourt, *De natura et praeclaro usu simplicissimae speciei numerorum trigonalium* (The Hague, 1762), contains a table of triangular numbers up to 20,000: viz. $\frac{1}{2}n(n+1)$ is given for all numbers from $n=1$ to 20,000. The table occupies 224 pages.

Reciprocals.—P. Barlow's *Tables* (1814 and 1840) give reciprocals up to 10,000 to 9 or 10 places; and a table of ten times this extent is given by W. H. Oakes, *Table of the Reciprocals of Numbers from 1 to 100,000* (London, 1865). This table gives seven figures of the reciprocal, and is arranged like a table of seven-figure logarithms, differences being added at the side of the page. The reciprocal

[1] Only one other multiplication table of the same extent as Crelle's had appeared previously, viz. Herwart von Hohenburg's *Tabulae arithmeticae προσθαφαιρέσεως universales* (Munich, 1610), a huge folio volume of more than a thousand pages. It appears from a correspondence between Kepler and von Hohenburg, which took place at the end of 1608, that the latter used his table when in manuscript for the performance of multiplications in general, and that the occurrence of the word *prosthaphaeresis* on the title is due to Kepler, who pointed out that by means of the table spherical triangles could be solved more easily than by Wittich's prosthaphaeresis. The invention of logarithms four years later afforded another means of performing multiplications, and von Hohenburg's work never became generally known. On the method of prosthaphaeresis, see NAPIER, JOHN, and on von Hohenburg's table, see a paper "On multiplication by a Table of Single Entry," *Phil. Mag.*, 1878, ser. v., 6, p. 331.

[2] The actual place of publication (with a German title, &c.) is Vienna. The copies with an English title, &c., were issued by Trübner; and those with a French title, &c., by Gauthier-Villars. All bear the date 1888.

of a number of five figures is therefore taken out at once, and two more figures may be interpolated for as in logarithms. R. Picarte, *La Division réduite à une addition* (Paris, 1861), gives to ten significant figures the reciprocals of the numbers from 10,000 to 100,000, and also the first nine multiples of these reciprocals. J. C. Houzeau gives the reciprocals of numbers up to 100 to 20 places and their first nine multiples to 12 places in the *Bulletin of the Brussels Academy*, 1875, 40, p. 107. E. Gélin (*Recueil de tables numériques*, Huy, 1894) gives reciprocals of numbers to 1000 to 10 places.

Tables for the Expression of Vulgar Fractions as Decimals.—Tables of this kind have been given by Wucherer, Goodwyn and Gauss. W. F. Wucherer, *Beyträge zum allgemeinern Gebrauch der Decimalbrüche* (Carlsruhe, 1796), gives the decimal fractions (to 5 places) for all vulgar fractions whose numerator and denominator are each less than 50 and prime to one another, arranged according to denominators. The most extensive and elaborate tables that have been published are contained in Henry Goodwyn's *First Centenary of Tables of all Decimal Quotients* (London, 1816), *A Tabular Series of Decimal Quotients* (1823), and *A Table of the Circles arising from the Division of a Unit or any other Whole Number by all the Integers from 1 to 1024* (1823). The *Tabular Series* (1823), which occupies 153 pages, gives to 8 places the decimal corresponding to every vulgar fraction less than $\frac{99}{991}$ whose numerator and denominator do not surpass 1000. The arguments are not arranged according to their numerators or denominators, but according to their magnitude, so that the tabular results exhibit a steady increase from ·001 ($=\frac{1}{1000}$) to ·09989909 ($=\frac{99}{991}$). The author intended the table to include all fractions whose numerator and denominator were each less than 1000, but no more was ever published. The *Table of Circles* (1823) gives all the periods of the circulating decimals that can arise from the division of any integer by another integer less than 1024. Thus for 13 we find $\cdot\dot{0}7692\dot{3}$ and $\cdot\dot{1}5384\dot{6}$, which are the only periods in which a fraction whose denominator is 13 can circulate. The table occupies 107 pages, some of the periods being of course very long (*e.g.*, for 1021 the period contains 1020 figures). The *First Centenary* (1816) gives the complete periods of the reciprocals of the numbers from 1 to 100. Goodwyn's tables are very scarce, but as they are nearly unique of their kind they deserve special notice. A second edition of the *First Centenary* was issued in 1818 with the addition of some of the *Tabular Series*, the numerator not exceeding 50 and the denominator not exceeding 100. A posthumous table of C. F. Gauss's, entitled "Tafel zur Verwandlung gemeiner Brüche mit Nennern aus dem ersten Tausend in Decimalbrüche," occurs in vol. ii. pp. 412–434 of his *Gesammelte Werke* (Göttingen, 1863), and resembles Goodwyn's *Table of Circles*. On this subject see a paper "On Circulating Decimals, with special reference to Henry Goodwyn's *Table of Circles* and *Tabular Series of Decimal Quotients*," in *Camb. Phil. Proc.*, 1878, 3, p. 185, where is also given a table of the numbers of digits in the periods of fractions corresponding to denominators prime to 10 from 1 to 1024 obtained by counting from Goodwyn's table. See also under *Circulating Decimals* (below).

Sexagesimal and Sexcentenary Tables.—Originally all calculations were sexagesimal; and the relics of the system still exist in the division of the degree into 60 minutes and the minute into 60 seconds. To facilitate interpolation, therefore, in trigonometrical and other tables the following large sexagesimal tables were constructed. John Bernoulli, *A Sexcentenary Table* (London, 1779), gives at once the fourth term of any proportion of which the first term is 600″ and each of the other two is less than 600″; the table is of double entry, and may be described as giving the value of $xy/600$ correct to tenths of a second, x and y each containing a number of seconds less than 600. Michael Taylor, *A Sexagesimal Table* (London, 1780), exhibits at sight the fourth term of any proportion where the first term is 60 minutes, the second any number of minutes less than 60, and the third any number of minutes and seconds under 60 minutes; there is also another table in which the third term is any absolute number under 1000. Not much use seems to have been made of these tables, both of which were published by the Commissioners of Longitude. Small tables for the conversion of sexagesimals into centesimals and vice versa are given in a few collections, such as Hülsse's edition of Vega. H. Schubert's *Fünfstellige Tafeln und Gegentafeln* (Leipzig, 1897) contains a sexagesimal table giving $xy/60$ for $x=1$ to 59 and $y=1$ to 150.

Trigonometrical Tables (Natural).—Peter Apian published in 1533 a table of sines with the radius divided decimally. The first complete canon giving all the six ratios of the sides of a right-angled triangle is due to Rheticus (1551), who also introduced the semiquadrantal arrangement. Rheticus's canon was calculated for every ten minutes to 7 places, and Vieta extended it to every minute (1579). In 1554 Reinhold published a table of tangents to every minute. The first complete canon published in England was by Thomas Blundeville (1594), although a table of sines had appeared four years earlier. Regiomontanus called his table of tangents (or rather cotangents) *tabula foecunda* on account of its great use; and till the introduction of the word "tangent" by Thomas Finck (*Geometriae rotundi libri XIV.*, Basel, 1583) a table of tangents was called a *tabula foecunda* or *canon foecundus*. Besides "tangent," Finck also introduced the word "secant," the table of secants having previously been called *tabula benefica* by Maurolycus (1558) and *tabula foecundissima* by Vieta.

By far the greatest computer of pure trigonometrical tables is George Joachim Rheticus, whose work has never been superseded. His celebrated ten-decimal canon, the *Opus palatinum*, was published by Valentine Otho at Neustadt in 1596, and in 1613 his fifteen-decimal table of sines by Pitiscus at Frankfort under the title *Thesaurus mathematicus*. The *Opus palatinum* contains a complete ten-decimal trigonometrical canon for every ten seconds of the quadrant, semiquadrantally arranged, with differences for all the tabular results throughout. Sines, cosines, and secants are given on the left-hand pages in columns headed respectively "Perpendiculum," "Basis," "Hypotenusa," and on the right-hand pages appear tangents, cosecants, and cotangents in columns headed respectively "Perpendiculum," "Hypotenusa," "Basis." At his death Rheticus left the canon nearly complete, and the trigonometry was finished and the whole edited by Valentine Otho; it was named in honour of the elector palatine Frederick IV., who bore the expense of publication. The *Thesaurus* of 1613 gives natural sines for every ten seconds throughout the quadrant, to 15 places, semiquadrantally arranged, with first, second, and third differences. Natural sines are also given for every second from 0° to 1° and from 89° to 90°, to 15 places, with first and second differences. The rescue of the manuscript of this work by Pitiscus forms a striking episode in the history of mathematical tables. The alterations and emendations in the earlier part of the corrected edition of the *Opus palatinum* were made by Pitiscus, who had his suspicions that Rheticus had himself calculated a ten-second table of sines to 15 decimal places; but it could not be found. Eventually the lost canon was discovered amongst the papers of Rheticus which had passed from Otho to James Christmann on the death of the former. Amongst these Pitiscus found (1) the ten-second table of sines to 15 places, with first, second, and third differences (printed in the *Thesaurus*); (2) sines for every second of the first and last degrees of the quadrant, also to 15 places, with first and second differences; (3) the commencement of a canon of tangents and secants, to the same number of decimal places, for every ten seconds, with first and second differences; (4) a complete minute canon of sines, tangents, and secants, also to 15 decimal places. This list, taken in connexion with the *Opus palatinum*, gives an idea of the enormous labours undertaken by Rheticus; his tables not only remain to this day the ultimate authorities but formed the data from which Vlacq calculated his logarithmic canon. Pitiscus says that for twelve years Rheticus constantly had computers at work.

A history of trigonometrical tables by Charles Hutton was prefixed to all the early editions of his *Tables of Logarithms*, and forms Tract xix. of his *Mathematical Tracts*, vol. i. p. 278, 1812. A good deal of bibliographical information about the *Opus palatinum* and earlier trigonometrical tables is given in A. De Morgan's article "Tables" in the *English Cyclopaedia*. The invention of logarithms the year after the publication of Rheticus's volume by Pitiscus changed all the methods of calculation; and it is worthy of note that John Napier's original table of 1614 was a logarithmic canon of sines and not a table of the logarithms of numbers. The logarithmic canon at once superseded the natural canon; and since Pitiscus's time no really extensive table of pure trigonometrical functions has appeared. In recent years the employment of calculating machines has revived the use of tables of natural trigonometrical functions, it being found convenient for some purposes to employ such a machine in connexion with a natural canon instead of using a logarithmic canon. A. Junge's *Tafel der wirklichen Länge der Sinus und Cosinus* (Leipzig, 1864) was published with this object. It gives natural sines and cosines for every ten seconds of the quadrant to 6 places. F. M. Clouth, *Tables pour le calcul des coordonnées goniométriques* (Mainz, n.d.), gives natural sines and cosines (to 6 places) and their first nine multiples (to 4 places) for every centesimal minute of the quadrant. Tables of natural functions occur in many collections, the natural and logarithmic values being sometimes given on opposite pages, sometimes side by side on the same page.

The following works contain tables of trigonometrical functions other than sines, cosines, and tangents. J. Pasquich, *Tabulae logarithmico-trigonometricae* (Leipzig, 1817), contains a table of $\sin^2 x$, $\cos^2 x$, $\tan^2 x$, $\cot^2 x$ from $x=1°$ to $45°$ at intervals of 1′ to 5 places. J. Andrew, *Astronomical and Nautical Tables* (London, 1805), contains a table of "squares of natural semichords," *i.e.* of $\sin^2 \frac{1}{2}x$ from $x=0°$ to $120°$ at intervals of 10″ to 7 places. This table was greatly extended by Major-General Hannyngton in his *Haversines, Natural and Logarithmic, used in computing Lunar Distances for the Nautical Almanac* (London, 1876). The name "haversine," frequently used in works upon navigation, is an abbreviation of "half versed sine"; viz., the haversine of x is equal to $\frac{1}{2}(1-\cos x)$, that is, to $\sin^2\frac{1}{2}x$. The table gives logarithmic haversines for every 15″ from 0° to 180°, and natural haversines for every 10″ from 0° to 180°, to 7 places, except near the beginnng, where the logarithms are given to only 5 or 6 places. It occupies

327 folio pages, and was suggested by Andrew's work, a copy of which by chance fell into Hannyngton's hands. Hannyngton recomputed the whole of it by a partly mechanical method, a combination of two arithmometers being employed. A table of haversines is useful for the solution of spherical triangles when two sides and the included angle are given, and in other problems in spherical trigonometry. Andrew's original table seems to have attracted very little notice. Hannyngton's was printed, on the recommendation of the superintendent of the *Nautical Almanac* office, at the public cost. Before the calculation of Hannyngton's table R. Farley's *Natural Versed Sines* (London, 1856) was used in the *Nautical Almanac* office in computing lunar distances. This fine table contains natural versed sines from 0° to 125° at intervals of 10″ to 7 places, with proportional parts, and log versed sines from 0° to 135° at intervals of 15″ to 7 places. The arguments are also given in time. The manuscript was used in the office for twenty-five years before it was printed. Traverse tables, which occur in most collections of navigation tables, contain multiples of sines and cosines.

Common or Briggian Logarithms of Numbers and Trigonometrical Ratios.—For an account of the invention and history of logarithms, see LOGARITHM. The following are the fundamental works which contain the results of the original calculations of logarithms of numbers and trigonometrical ratios:—Briggs, *Arithmetica logarithmica* (London, 1624), logarithms of numbers from 1 to 20,000 and from 90,000 to 100,000 to 14 places, with interscript differences; Vlacq, *Arithmetica logarithmica* (Gouda, 1628, also an English edition, London, 1631, the tables being the same), ten-figure logarithms of numbers from 1 to 100,000, with differences, also log sines, tangents, and secants for every minute of the quadrant to 10 places, with interscript differences; Vlacq, *Trigonometria artificialis* (Gouda, 1633), log sines and tangents to every ten seconds of the quadrant to 10 places, with differences, and ten-figure logarithms of numbers up to 20,000, with differences; Briggs, *Trigonometria Britannica* (London, 1633), natural sines to 15 places, tangents and secants to 10 places, log sines to 14 places, and tangents to 10 places, at intervals of a hundredth of a degree from 0° to 45°, with interscript differences for all the functions. In 1794 Vega reprinted at Leipzig Vlacq's two works in a single folio volume, *Thesaurus logarithmorum completus*. The arrangement of the table of logarithms of numbers is more compendious than in Vlacq, being similar to that of an ordinary seven-figure table, but it is not so convenient, as mistakes in taking out the differences are more liable to occur. The trigonometrical canon gives log sines, cosines, tangents, and cotangents, from 0° to 2° at intervals of one second, to 10 places, without differences, and for the rest of the quadrant at intervals of ten seconds. The trigonometrical canon is not wholly reprinted from the *Trigonometria artificialis*, as the logarithms for every second of the first two degrees, which do not occur in Vlacq, were calculated for the work by Lieutenant Dorfmund. Vega devoted great attention to the detection of errors in Vlacq's logarithms of numbers, and has given several important errata lists. F. Lefort (*Annales de l'Observatoire de Paris*, vol. iv.) has given a full errata list in Vlacq's and Vega's logarithms of numbers, obtained by comparison with the great French manuscript *Tables du cadastre* (see LOGARITHM; comp. also *Monthly Notices R.A.S.*, 32, pp. 255, 288; 33, p. 330; 34, p. 447). Vega seems not to have bestowed on the trigonometrical canon anything like the care that he devoted to the logarithms of numbers, as Gauss[1] estimates the total number of last-figure errors at from 31,983 to 47,746, most of them only amounting to a unit, but some to as much as 3 or 4.

A copy of Vlacq's *Arithmetica logarithmica* (1628 or 1631), with the errors in numbers, logarithms, and differences corrected, is still the best table for a calculator who has to perform work requiring ten-figure logarithms of numbers, but the book is not easy to procure, and Vega's *Thesaurus* has the advantage of having log sines, &c., in the same volume. The latter work also has been made more accessible by a photographic reproduction by the Italian government (*Riproduzione fotozincografica dell' Istituto Geografico Militare*, Florence, 1896). In 1897 Max Edler von Leber published tables for facilitating interpolations in Vega's *Thesaurus* (*Tabularum ad faciliorem et breviorem in Georgii Vegae "Thesauri logarithmorum" magnis canonibus interpolationis computationem utilium Trias*, Vienna, 1897). The object of these tables is to take account of second differences. Prefixed to the tables is a long list of errors in the *Thesaurus*, occupying twelve pages. From an examination of the tabular results in the trigonometrical canon corresponding to 1060 angles von Leber estimates that out of the 90,720 tabular results 40,396 are in error by ± 1, 2793 by ±2, and 191 by ±3. Thus his estimated value of the total number of last-figure errors is 43,326, which is in accordance with Gauss's estimate. A table of ten-figure logarithms of numbers up to 100,009, the result of a new calculation, was published in the *Report of the U.S. Coast and Geodetic Survey for* 1895–6 (appendix 12, pp. 395–722) by W. W. Duffield, superintendent of the survey. The table was compared with Vega's *Thesaurus* before publication.

S. Pineto's *Tables de logarithmes vulgaires à dix décimales, construites d'après un nouveau mode* (St Petersburg, 1871), though a tract of only 80 pages, may be usefully employed when Vlacq and Vega are unprocurable. Pineto's work consists of three tables: the first, or auxiliary table, contains a series of factors by which the numbers whose logarithms are required are to be multiplied to bring them within the range of table 2; it also gives the logarithms of the reciprocals of these factors to 12 places. Table 1 merely gives logarithms to 1000 to 10 places. Table 2 gives logarithms from 1,000,000 to 1,011,000, with proportional parts to hundredths. The mode of using these tables is as follows. If the logarithm cannot be taken out directly from table 2, a factor M is found from the auxiliary table by which the number must be multiplied to bring it within the range of table 2. Then the logarithm can be taken out, and, to neutralize the effect of the multiplication, so far as the result is concerned, log $1/M$ must be added; this quantity is therefore given in an adjoining column to M in the auxiliary table. A similar procedure gives the number answering to any logarithm, another factor (approximately the reciprocal of M) being given, so that in both cases multiplication is used. The laborious part of the work is the multiplication by M; but this is somewhat compensated for by the ease with which, by means of the proportional parts, the logarithm is taken out. The factors are 300 in number, and are chosen so as to minimize the labour, only 25 of the 300 consisting of three figures all different and not involving 0 or 1. The principle of multiplying by a factor which is subsequently cancelled by subtracting its logarithm is used also in a tract, containing only ten pages, published by A. Namur and P. Mansion at Brussels in 1877 under the title *Tables de logarithmes à 12 décimales jusqu'à 434 milliards.* Here a table is given of logarithms of numbers near to 434,294, and other numbers are brought within the range of the table by multiplication by one or two factors. The logarithms of the numbers near to 434,294 are selected for tabulation because their differences commence with the figures 100 . . . and the presence of the zeros in the difference renders the interpolation easy.

The tables of S. Gundelfinger and A. Nell (*Tafeln zur Berechnung neunstelliger Logarithmen*, Darmstadt, 1891) afford an easy means of obtaining nine-figure logarithms, though of course they are far less convenient than a nine-figure table itself. The method in effect consists in the use of Gaussian logarithms, viz., if $N = n + p$, $\log N = \log n + \log(1 + p/n) = \log n + B$ where B is $\log(1 + p/n)$ to argument $A = \log p - \log n$. The tables give $\log n$ from $n = 1000$ to $n = 10{,}000$, and values of B for argument A.[2]

Until 1891, when the eight-decimal tables, referred to further on, were published by the French government, the computer who could not obtain sufficiently accurate results from seven-figure logarithms was obliged to have recourse to ten-figure tables, for, with only one exception, there existed no tables giving eight or nine figures. This exception is John Newton's *Trigonometria Britannica* (London, 1658), which gives logarithms of numbers to 100,000 to 8 places, and also log sines and tangents for every centesimal minute (*i.e.* the nine-thousandth part of a right angle), and also log sines and tangents for the first three degrees of the quadrant to 5 places, the interval being the one-thousandth part of a degree. This table is also remarkable for giving the logarithms of the differences instead of the actual differences. The arrangement of the page now universal in seven-figure tables—with the fifth figures running horizontally along the top line of the page—is due to John Newton.

As a rule seven-figure logarithms of numbers are not published separately, most tables of logarithms containing both the logarithms of numbers and a trigonometrical canon. Babbage's and Sang's logarithms are exceptional and give logarithms of numbers only. C. Babbage, *Table of the Logarithms of the Natural Numbers from 1 to* 108,000 (London, stereotyped in 1827; there are many tirages of later dates), is the best for ordinary use. Great pains were taken to get the maximum of clearness. The change of figure in the middle of the block of numbers is marked by a change of type in the fourth figure, which (with the sole exception of the asterisk) is probably the best method that has been used. Copies of the book were printed on paper of different colours—yellow, brown, green, &c.—as it was considered that black on a white ground was a fatiguing combination for the eye. The tables were also issued with title-pages and introductions in other languages. In 1871 E. Sang published *A New Table of Seven-place Logarithms of all Numbers from* 20,000 to 200,000 (London). In an ordinary table extending from 10,000 to 100,000 the differences near the beginning are so numerous that the proportional parts are either very crowded or some of them omitted; by making the table extend from 20,000 to 200,000 instead of from 10,000 to 100,000 the differences are halved in magnitude, while there are only one-fourth as many in a page. There is also greater accuracy. A

[1] See his "Einige Bemerkungen zu Vega's *Thesaurus logarithmorum*," in *Astronomische Nachrichten* for 1851 (reprinted in his *Werke*, vol. iii. pp. 257–64); also *Monthly Notices R.A.S.*, 33, p. 440.

[2] A seven-figure table of the same kind is contained in S. Gundelfinger's *Sechsstellige Gaussische und siebenstellige gemeine Logarithmen* (Leipzig, 1902).

further peculiarity of this table is that multiples of the differences, instead of proportional parts, are given at the side of the page. Typographically the table is exceptional, as there are no rules, the numbers being separated from the logarithms by reversed commas —a doubtful advantage. This work was to a great extent the result of an original calculation; see *Trans. Roy. Soc. Edin.*, 1871, 26. Sang proposed to publish a nine-figure table from 1 to 1,000,000, but the requisite support was not obtained. Various papers of Sang's relating to his logarithmic calculations will be found in the *Proc. Roy. Soc. Edin.* subsequent to 1872. Reference should here be made to Abraham Sharp's table of logarithms of numbers from 1 to 100 and of primes from 100 to 1100 to 61 places, also of numbers from 999,990 to 1,000,010 to 63 places. These first appeared in *Geometry Improv'd . . . by A. S. Philomath* (London, 1717). They have been republished in Sherwin's, Callet's, and the earlier editions of Hutton's tables. H. M. Parkhurst, *Astronomical Tables* (New York, 1871), gives logarithms of numbers from 1 to 109 to 102 places.[1]

In many seven-figure tables of logarithms of numbers the values of S and T are given at the top of the page, with V, the variation of each, for the purpose of deducing log sines and tangents. S and T denote log (sin x/x) and log (tan x/x) respectively, the argument being the number of seconds denoted by certain numbers (sometimes only the first, sometimes every tenth) in the number column on each page. Thus, in Callet's tables, on the page on which the first number is 67200, $S=$log (sin 6720″/6720) and $T=$log (tan 6720″/6720), while the V's are the variations of each for 10″. To find, for example, log sin 1°52′12″·7, or log sin 6732″·7, we have $S=$4·6854980 and log 6732·7 = 3,8281893, whence, by addition, we obtain 8·5136873; but V for 10″ is − 2·29, whence the variation for 12″·7 is −3, and the log sine required is 8·5136870. Tables of S and T are frequently called, after their inventor, "Delambre's tables."

Some seven-figure tables extend to 100,000, and others to 108,000, the last 8000 logarithms, to 8 places, being given to ensure greater accuracy, as near the beginning of the numbers the differences are large and the interpolations more laborious and less exact than in the rest of the table. The eight-figure logarithms, however, at the end of a seven-figure table are liable to occasion error; for the computer who is accustomed to three leading figures, common to the block of figures, may fail to notice that in this part of the table there are four, and so a figure (the fourth) is sometimes omitted in taking out the logarithm. In the ordinary method of arranging a seven-figure table the change in the fourth figure, when it occurs in the course of the line, is a source of frequent error unless it is very clearly indicated. In the earlier tables the change was not marked at all, and the computer had to decide for himself, each time he took out a logarithm, whether the third figure had to be increased. In some tables the line is broken where the change occurs; but the dislocation of the figures and the corresponding irregularity in the lines are very awkward. Babbage printed the fourth figure in small type after a change; and Bremiker placed a bar over it. The best method seems to be that of prefixing an asterisk to the fourth figure of each logarithm after the change, as is done in Schrön's and many other modern tables. This is beautifully clear and the asterisk at once catches the eye. Shortrede and Sang replace 0 after a change by a *nokta* (resembling a diamond in a pack of cards). This is very clear in the case of the 0's, but leaves unmarked the cases in which the fourth figure is 1 or 2. A method which finds favour in some recent tables is to underline all the figures after the increase, or to place a line over them.

Babbage printed a subscript point under the last figure of each logarithm that had been increased. Schrön used a bar subscript, which, being more obtrusive, seems less satisfactory. In some tables the increase of the last figure is only marked when the figure is increased to a 5, and then a Roman five (v) is used in place of the Arabic figure.

Hereditary errors in logarithmic tables are considered in two papers "On the Progress to Accuracy of Logarithmic Tables" and "On Logarithmic Tables," in *Monthly Notices R.A.S.*, 33, pp. 330, 440. See also vol. 34, p. 447; and a paper by Gernerth, *Ztsch. f. d. österr. Gymm.*, Heft vi. p. 407.

Passing now to the logarithmic trigonometrical canon, the first great advance after the publication of the *Trigonometria artificialis* in 1633 was made in Michael Taylor's *Tables of Logarithms* (London, 1792), which give log sines and tangents to every second of the quadrant to 7 places. This table contains about 450 pages with an average number of 7750 figures to the page, so that there are altogether nearly three millions and a half of figures. The change in the leading figures, when it occurs in a column, is not marked at all; and the table must be used with very great caution. In fact it is advisable to go through the whole of it, and fill in with ink the first 0 after the change, as well as make some mark that will catch the eye at the head of every column containing a change. The table was calculated by interpolation from the *Trigonometria artificialis* to 10 places and then reduced to 7, so that the last figure should always be correct. Partly on account of the absence of a mark to denote the change of figure in the column and partly on account of the size of the table and a somewhat inconvenient arrangement, the work seems never to have come into general use. Computers have always preferred V. Bagay's *Nouvelles Tables astronomiques et hydrographiques* (Paris, 1829), which also contains a complete logarithmic canon to every second. The change in the column is very clearly marked by a large black nucleus, surrounded by a circle, printed instead of 0. Bagay's work having become rare and costly was reprinted with the errors corrected. The reprint, however, bears the original title-page and date 1829, and there appears to be no means of distinguishing it from the original work except by turning to one of the errata in the original edition and examining whether the correction has been made.

The only other canon to every second that has been published is contained in R. Shortrede's *Logarithmic Tables* (Edinburgh). This work was originally issued in 1844 in one volume, but being dissatisfied with it Shortrede issued a new edition in 1849 in two volumes. The first volume contains logarithms of numbers, antilogarithms, &c., and the second the trigonometrical canon to every second. The volumes are sold separately, and may be regarded as independent works; they are not even described on their title-pages as vol. i. and vol. ii. The trigonometrical canon is very complete in every respect, the arguments being given in time as well as in arc, full proportional parts being added, &c. The change of figure in the column is denoted by a nokta, printed instead of 0 where the change occurs. The page is crowded and the print not very clear, so that Bagay is to be preferred for regular use.

Previous to 1891 the only important tables in which the quadrant is divided centesimally were J. P. Hobert and L. Ideler, *Nouvelles tables trigonométriques* (Berlin, 1799), and C. Borda and J. B. J. Delambre, *Tables trigonométriques décimales* (Paris, 1801). The former give, among other tables, natural and log sines, cosines, tangents, and cotangents, to 7 places, the arguments proceeding to 3° at intervals of 10″ and thence to 50° at intervals of 1′ (centesimal), and also natural sines and tangents for the first hundred ten-thousandths of a right angle to 10 places. The latter gives long sines, cosines, tangents, cotangents, secants, and cosecants from 0° to 3° at intervals of 10″ (with full proportional parts for every second), and thence to 50° at intervals of 1′ (centesimal) to 7 places. There is also a table of log sines, cosines, tangents, and cotangents from 0′ to 10′ at intervals of 10″ and from 0° to 50° at intervals of 10′ (centesimal) to 11 places. Hobert and Ideler give a natural as well as a logarithmic canon; but Borda and Delambre give only the latter. Borda and Delambre give seven-figure logarithms of numbers to 10,000, the line being broken when a change of figure takes place in it.

The tables of Borda and Delambre having become difficult to procure, and seven-figure tables being no longer sufficient for the accuracy required in astronomy and geodesy, the French government in 1891 issued an eight-figure table containing (besides logarithms of numbers to 120,000) log sines and tangents for every ten seconds (centesimal) of the quadrant, the latter being extracted from the *Tables du cadastre* of Prony (see LOGARITHM). The title of this fine and handsomely printed work is *Service géographique de l'armée: Tables des logarithmes à huit décimales . . . publiées par ordre du ministre de la guerre* (Paris, Imprimerie Nationale, 1891). These tables are now in common use where eight figures are required.

In Brigg's *Trigonometria Britannica* of 1633 the degree is divided centesimally, and but for the appearance in the same year of Vlacq's *Trigonometria artificialis*, in which the degree is divided sexagesimally, this reform might have been effected. It is clear that the most suitable time for making such a change was when the natural canon was replaced by the logarithmic canon, and Briggs took advantage of this opportunity. He left the degree unaltered, but divided it centesimally instead of sexagesimally, thus ensuring the advantages of decimal division (a saving of work in interpolations, multiplications, &c.) with the minimum of change. The French mathematicians at the end of the 18th century divided the right angle centesimally, completely changing the whole system, with no appreciable advantages over Briggs's system. In fact the centesimal degree is as arbitrary a unit as the nonagesimal and it is only the non-centesimal subdivision of the degree that gives rise to inconvenience. Briggs's example was followed by Roe, Oughtred, and other 17th-century writers; but the centesimal division of the degree seemed to have entirely passed out of use, till it was revived by C. Bremiker in his *Logarithmisch-trigonometrische Tafeln mit fünf Decimalstellen* (Berlin, 1872, 10th ed. revised by A. Kallius, 1906). This little book of 158 pages gives a five-figure canon to every hundredth of a degree with proportional parts, besides logarithms of numbers, addition and subtraction logarithms, &c.

The eight-figure table of 1891 has now made the use of a centesimal table compulsory, if this number of figures is required.

[1] Legendre (*Traité des fonctions elliptiques*, vol. ii., 1826) gives a table of natural sines to 15 places, and of log sines to 14 places, for every 15″ of the quadrant, and also a table of logarithms of uneven numbers from 1163 to 1501, and of primes from 1501 to 10,000 to 19 places. The latter, which was extracted from the *Tables du cadastre*, is a continuation of a table in W. Gardiner's *Tables of Logarithms* (London, 1742; reprinted at Avignon, 1770), which gives logarithms of all numbers to 1000, and of uneven numbers from 1000 to 1143. Legendre's tables also appeared in his *Exercices de calcul intégral*, vol. iii. (1816).

The *Astronomische Gesellschaft* are, however, publishing an eight-figure table on the sexagesimal system, under the charge of Dr. J. Bauschinger, the director of the k. Recheninstitut at Berlin. The arrangement is to be in groups of three as in Bremiker's tables.

Collections of Tables.—For a computer who requires in one volume logarithms of numbers and a ten-second logarithmic canon, perhaps the two best books are L. Schrön, *Seven-Figure Logarithms* (London, 1865, stereotyped, an English edition of the German work published at Brunswick), and C. Bruhns, *A New Manual of Logarithms to Seven Places of Decimals* (Leipzig, 1870). Both these works (of which there have been numerous editions) give logarithms of numbers and a complete ten-second canon to 7 places; Bruhns also gives log sines, cosines, tangents, and cotangents to every second up to 6° with proportional parts. Schrön contains an interpolation table, of 75 pages, giving the first 100 multiples of all numbers from 40 to 420. The logarithms of numbers extend to 108,000 in Schrön and to 100,000 in Bruhns. Almost equally convenient is Bremiker's edition of Vega's *Logarithmic Tables* (Berlin, stereotyped; the English edition was translated from the fortieth edition of Bremiker's by W. L. F. Fischer). This book gives a canon to every ten seconds, and for the first five degrees to every second, with logarithms of numbers to 100,000. Schrön, Bruhns, and Bremiker all give the proportional parts for all the differences in the logarithms of numbers. In Babbage's, Callet's, and many other tables only every other table of proportional parts is given near the beginning for want of space. Schrön, Bruhns, and most modern tables published in Germany have title-pages and introductions in different languages. J. Dupuis, *Tables de logarithmes à sept décimales* (stereotyped, third tirage, 1868, Paris), is also very convenient, containing a ten-second canon, besides logarithms of numbers to 100,000, hyperbolic logarithms of numbers to 1000, to 7 places, &c. In this work negative characteristics are printed throughout in the tables of circular functions, the minus sign being placed above the figure; for the mathematical calculator these are preferable to the ordinary characteristics that are increased by 10. The edges of the pages containing the circular functions are red, the rest being grey. Dupuis also edited Callet's logarithms in 1862, with which this work must not be confounded. J. Salomon, *Logarithmische Tafeln* (Vienna, 1827), contains a ten-second canon (the intervals being one second for the first two degrees), logarithms of numbers to 108,000, squares, cubes, square roots, and cube roots to 1000, a factor table to 102,011, ten-place Briggian and hyperbolic logarithms of numbers to 1000 and of primes to 10,333, and many other useful tables. The work, which is scarce, is a well-printed small quarto volume.

Of collections of general tables among the most useful and accessible are Hutton, Callet, Vega, and Köhler. C. Hutton's well-known *Mathematical Tables* (London) was first issued in 1785, but considerable additions were made in the fifth edition (1811). The tables contain seven-figure logarithms to 108,000, and to 1200 to 20 places, some antilogarithms to 20 places, hyperbolic logarithms from 1 to 10 at intervals of ·01 and to 1200 at intervals of unity to 7 places, logistic logarithms, log sines and tangents to every second of the first two degrees, and natural and log sines, tangents, secants, and versed sines for every minute of the quadrant to 7 places. The natural functions occupy the left-hand pages and the logarithmic the right-hand. The first six editions, published in Hutton's lifetime (d. 1823), contain Abraham Sharp's 61-figure logarithms of numbers. Olinthus Gregory, who brought out the 1830 and succeeding editions, omitted these tables and Hutton's introduction, which contains a history of logarithms, the methods of constructing them, &c. F. Callet's *Tables portatives de logarithmes* (stereotyped, Paris) seems to have been first issued in 1783, and has since passed through a great many editions. In that of 1853 the contents are seven-figure logarithms to 108,000, Briggian and hyperbolic logarithms to 48 places of numbers to 100 and of primes to 1097, log sines and tangents for minutes (centesimal) throughout the quadrant to 7 places, natural and log sines to 15 places for every ten minutes (centesimal) of the quadrant, log sines and tangents for every second of the first five degrees (sexagesimal) and for every ten seconds of the quadrant (sexagesimal) to 7 places, besides logistic logarithms, the first hundred multiples of the modulus to 24 places and the first ten to 70 places, and other tables. This is one of the most complete and practically useful collections of logarithms that have been published, and it is peculiar in giving a centesimally divided canon. The size of the page in the editions published in the 19th century is larger than that of the earlier editions, the type having been reset. G. Vega's *Tabulae logarithmo-trigonometricae* was first published in 1797 in two volumes. The first contains seven-figure logarithms to 101,000, log sines, &c., for every tenth of a second to 1′, for every second to 1° 30′, for every 10″ to 6° 3′, and thence at intervals of a minute, also natural sines and tangents to every minute, all to 7 places. The second volume gives simple divisors of all numbers up to 102,000, a list of primes from 102,000 to 400,313, hyperbolic logarithms of numbers to 1000 and of primes to 10,000, to 8 places, e^x and $\log_{10}e^x$ to $x=10$ at intervals of ·01 to 7 figures and 7 places respectively, the first nine powers of the numbers from 1 to 100, squares and cubes to 1000, logistic logarithms, binomial theorem coefficients, &c. Vega also published *Manuale logarithmico-trigonometricum* (Leipzig, 1800), the tables in which are identical with a portion of those contained in the first volume of the *Tabulae*. The *Tabulae* went through many editions, a stereotyped issue being brought out by J. A. Hülsse (*Sammlung mathematischer Tafeln*, Leipzig) in one volume in 1840. The contents are nearly the same as those of the original work, the chief difference being that a large table of Gaussian logarithms is added. Vega differs from Hutton and Callet in giving so many useful non-logarithmic tables, and his collection is in many respects complementary to theirs. J. C. Schulze, *Neue und erweiterte Sammlung logarithmischer, trigonometrischer, und anderer Tafeln* (2 vols. Berlin, 1778), is a valuable collection, and contains seven-figure logarithms to 101,000, log sines and tangents to 2° at intervals of a second, and natural sines, tangents, and secants to 7 places, log sines and tangents and *Napierian* log sines and tangents to 8 places, all for every ten seconds to 4° and thence for every minute to 45°, besides squares, cubes, square roots, and cube roots to 1000, binomial theorem coefficients, powers of e, and other small tables. Wolfram's hyperbolic logarithms of numbers below 10,000 to 48 places first appeared in this work. J. H. Lambert's *Supplementa tabularum logarithmicarum et trigonometricarum* (Lisbon, 1798) contains a number of useful and curious non-logarithmic tables and bears a general resemblance to the second volume of Vega, but there are also other small tables of a more strictly mathematical character. A very useful collection of non-logarithmic tables is contained in Peter Barlow's *New Mathematical Tables* (London, 1814). It gives squares, cubes, square roots, and cube roots (to 7 places), reciprocals to 9 or 10 places, and resolutions into their prime factors of all numbers from 1 to 10,000, the first ten powers of numbers to 100, fourth and fifth powers of numbers from 100 to 1000, prime numbers from 1 to 100,103, eight-place hyperbolic logarithms to 10,000, tables for the solution of the irreducible case in cubic equations, &c. In the stereotyped reprint of 1840 only the squares, cubes, square roots, cube roots, and reciprocals are retained. The first volume of Shortrede's tables, in addition to the trigonometrical canon to every second, contains antilogarithms and Gaussian logarithms. F. R. Hassler, *Tabulae logarithmicae et trigonometricae* (New York, 1830, stereotyped), gives seven-figure logarithms to 100,000, log sines and tangents for every second to 1°, and log sines, cosines, tangents, and cotangents from 1° to 3° at intervals of 10″ and thence to 45° at intervals of 30″. Every effort has been made to reduce the size of the tables without loss of distinctness, the page being only about 3 by 5 inches. Copies of the work were published with the introduction and title-page in different languages. A. D. Stanley, *Tables of Logarithms* (New Haven, U.S., 1860), gives seven-figure logarithms to 100,000, and log sines, cosines, tangents, cotangents, secants, and cosecants at intervals of ten seconds to 15° and thence at intervals of a minute to 45° to 7 places, besides natural sines and cosines, antilogarithms, and other tables. This collection owed its origin to the fact that Hassler's tables were found to be inconvenient owing to the smallness of the type. G. Luvini, *Tables of Logarithms* (London, 1866, stereotyped, printed at Turin), gives seven-figure logarithms to 20,040, Briggian and hyperbolic logarithms of primes to 1200 to 20 places, log sines and tangents for each second to 9′, at intervals of 10″ to 2°, of 30″ to 9°, of 1′ to 45° to 7 places, besides square and cube roots up to 625. The book, which is intended for schools, engineers, &c., has a peculiar arrangement of the logarithms and proportional parts on the pages. *Mathematical Tables* (W. & R. Chambers, Edinburgh), containing logarithms of numbers to 100,000, and a canon to every minute of log sines, tangents, and secants and of natural sines to 7 places, besides proportional logarithms and other small tables, is cheap and suitable for schools, though not to be compared as regards matter or typography to the best tables described above.

Of six-figure tables C. Bremiker's *Logarithmorum VI. decimalium nova tabula Berolinensis* (Berlin 1852) is probably one of the best. It gives logarithms of numbers to 100,000, with proportional parts, and log sines and tangents for every second to 5°, and beyond 5° for every ten seconds, with proportional parts. J. Hantschl, *Logarithmisch-trigonometrisches Handbuch* (Vienna, 1827), gives five-figure logarithms to 10,000, log sines and tangents for every ten seconds to 6 places, natural sines, tangents, secants, and versed sines for every minute to 7 places, logarithms of primes to 15,391, hyperbolic logarithms of numbers to 11,273 to 8 places, least divisors of numbers to 18,277, binomial theorem coefficients, &c. R. Farley's *Six-Figure Logarithms* (London, stereotyped, 1840), gives six-figure logarithms to 10,000 and log sines and tangents for every minute to 6 places.

Coming now to five-figure tables a very convenient little book is *Tables of Logarithms* (Useful Knowledge Society, London, from the stereotyped plates of 1839), which was prepared by De Morgan, though it has no name on the title-page. It contains five-figure logarithms to 10,000, log sines and tangents to every minute to 5 places, besides a few smaller tables. J. de Lalande's *Tables de logarithmes* is a five-figure table with nearly the same contents as De Morgan's, first published in 1805. It has since passed through many editions, and, after being extended from 5 to 7 places, passed through several more. J. Galbraith and S. Haughton, *Manual of Mathematical Tables* (London, 1860), give five-figure logarithms to 10,000 and log sines and tangents for every minute, also a small table of Gaussian logarithms. J. Houël, *Tables de logarithmes à cinq décimales* (Paris, 1871; new edition 1907), is a very convenient collection of five-figure tables; besides logarithms of numbers and circular functions, there are Gaussian logarithms, least divisors of numbers to 10,841, antilogarithms, &c. The work (118 pp.) is printed on thin paper. A. Gernerth, *Fünfstellige gemeine Logarithmen* (Vienna, 1866), gives logarithms to 10,800 and a ten-second canon. There are sixty lines on the page, so that the double page contains log sines, cosines, tangents, and cotangents extending over a minute. C. Bremiker, *Logarithmisch-trigonometrische Tafeln mit fünf Decimalstellen* (10th edition by A. Kallius, Berlin, 1906), which has been already referred to, gives logarithms to 10,009 and a logarithmic canon to *every hundredth* of a degree (sexagesimal), in a handy volume; the lines are divided into groups of three, an arrangement about the convenience of which there is a difference of opinion. H. Gravelius, *Fünfstellige logarithmisch-trigonometrische Tafeln für die Decimalteilung des Quadranten* (Berlin, 1886), is a well-printed five-figure table giving logarithms to 10,009, a logarithmic canon to every centesimal minute (*i.e.* ten-thousandth part of a right angle), and an extensive table (40 pp.) for the conversion of centesimally expressed arcs into sexagesimally expressed arcs and vice versa. Among the other tables is a four-place table of squares from 0 to 10 at intervals of ·001 with proportional parts. E. Becker, *Logarithmisch-trigonometrisches Handbuch auf fünf Decimalen* (2nd stereo. ed., Leipzig, 1897), gives logarithms to 10,009 and a logarithmic canon for every tenth of a minute to 6° and thence to 45° for every minute. There are also Gaussian logarithms. V. E. Gamborg, *Logaritmetabel* (Copenhagen, 1897), is a well-printed collection of tables, which contains a five-figure logarithmic canon to every minute, five-figure logarithms of numbers to 10,000, and five-figure antilogarithms, viz., five-figure numbers answering to four-figure mantissae from ·0000 to ·9999 at intervals of ·0001. H. Schubert, *Fünfstellige Tafeln und Gegentafeln* (Leipzig, 1896), is peculiar in giving, besides logarithms of numbers and a logarithmic and natural canon, the three converse tables of numbers answering to logarithms, and angles answering to logarithmic and natural trigonometrical functions. The five-figure tables of F. G. Gauss (Berlin, 1870) have passed through very many editions, and mention should also be made of those of T. Wittstein (Hanover, 1859) and F. W. Rex (Stuttgart, 1884). S. W. Holman, *Computation Rules and Logarithms* (New York, 1896), contains a well-printed and convenient set of tables including five-figure logarithms of numbers to 10,000 and a five-figure logarithmic canon to every minute, the actual characteristics (with the negative sign above the number) being printed, as in the tables of Dupuis, 1868, referred to above. There is also a four-place trigonometrical canon and four-place antilogarithms, reciprocals, square and cube roots, &c. G. W. Jones, *Logarithmic Tables* (4th ed., London, and Ithaca, N.Y., 1893), contains a five-place natural trigonometrical canon and a six-place logarithmic canon to every minute, six-place Gaussian and hyperbolic logarithms, besides a variety of four-place tables, including squares, cubes, quarter-squares, reciprocals, &c. The factor table has been already noticed. It is to be observed that the fourth edition is quite a distinct work from the third, which contained much fewer tables. J. B. Dale, *Five-figure Tables of Mathematical Functions* (London, 1903), is a book of 92 pages containing a number of small five-figure tables of functions which are not elsewhere to be found in one volume. Among the functions tabulated are elliptic functions of the first and second kind, the gamma function, Legendre's coefficients, Bessel's functions, sine, cosine, and exponential integrals, &c. J. Houël's *Recueil de formules et de tables numériques* (Paris, 1868) contains 19 tables, occupying 62 pages, most of them giving results to 4 places; they relate to very varied subjects—antilogarithms, Gaussian logarithms, logarithms of $1+x/1-x$ elliptic integrals, squares for use in the method of least squares, &c. C. Bremiker, *Tafel vierstelliger Logarithmen* (Berlin, 1874), gives four-figure logarithms, of numbers to 2009, log sines, cosines, tangents, and cotangents to 8° for every hundredth of a degree, and thence to 45° for every tenth of a degree, to 4 places. There are also Gaussian logarithms, squares from 0·000 to 13,500, antilogarithms, &c. The book contains 60 pages. It is not worth while to give a list of four-figure tables or other tables of small extent, which are very numerous, but mention may be made of J. M. Peirce, *Mathematical Tables chiefly to Four Figures* (Boston, U.S., 1879), 42 pp., containing also hyperbolic functions; W. Hall, *Four-figure Tables and Constants* (Cambridge, 1905), 60 pp., chiefly for nautical computation; A. du P. Denning, *Five-figure Mathematical Tables for School and Laboratory Purposes* (12 pp. of tables, large octavo); A. R. Hinks, *Cambridge Four-figure Mathematical Tables* (12 pp.). C. M. Willich, *Popular Tables* (London, 1853), is a useful book for an amateur; it gives Briggian and hyperbolic logarithms to 1200 to 7 places, squares, &c., to 343, &c.

Hyperbolic or Napierian or Natural Logarithms.—The logarithms invented by Napier and explained by him in the *Descriptio* (1614) were not the same as those now called natural or hyperbolic (viz., to base e), and very frequently also Napierian, logarithms. Napierian logarithms, strictly so called, have entirely passed out of use and are of purely historic interest; it is therefore sufficient to refer to the article LOGARITHM, where a full account is given. Apart from the inventor's own publications, the only strictly Napierian tables of importance are contained in Ursinus's *Trigonometria* (Cologne, 1624–1625) and Schulze's *Sammlung* (Berlin, 1778), the former being the largest that has been constructed. Logarithms to the base e, where e denotes 2·71828 . . ., were first published by J. Speidell, *New Logarithmes* (1619).

The most copious table of hyperbolic logarithms is Z. Dase, *Tafel der natürlichen Logarithmen* (Vienna, 1850), which extends from 1 to 1000 at intervals of unity and from 1000 to 10,500 at intervals of ·1 to 7 places, with differences and proportional parts, arranged as in an ordinary seven-figure table. By adding log 10 to the results the range is from 10,000 to 105,000 at intervals of unity. The table formed part of the *Annals of the Vienna Observatory* for 1851, but separate copies were printed. The most elaborate table of hyperbolic logarithms is due to Wolfram, who calculated to 48 places the logarithms of all numbers up to 2200, and of all primes (also of a great many composite numbers) between this limit and 10,009. Wolfram's results first appeared in Schulze's *Sammlung* (1778). Six logarithms which Wolfram had been prevented from computing by a serious illness were supplied in the *Berliner Jahrbuch*, 1783, p. 191. The complete table was reproduced in Vega's *Thesaurus* (1794), where several errors were corrected. Tables of hyperbolic logarithms are contained in the following collections:—Callet, all numbers to 100 and primes to 1097 to 48 places; Borda and Delambre (1801), all numbers to 1200 to 11 places; Salomon (1827), all numbers to 1000 and primes to 10,333 to 10 places; Vega, *Tabulae* (including Hülsse's edition, 1840), and Köhler (1848), all numbers to 1000 and primes to 10,000 to 8 places; Barlow (1814), all numbers to 10,000; Hutton, *Mathematical Tables*, and Willich (1853), all numbers to 1200 to 7 places; Dupuis (1868), all numbers to 1000 to 7 places. Hutton also gives hyperbolic logarithms from 1 to 10 at intervals of ·01 to 7 places. *Rees's Cyclopaedia* (1819), art, "Hyperbolic Logarithms," contains a table of hyperbolic logarithms of all numbers to 10,000 to 8 places.

Logarithms to base e are generally termed *Napierian* by English writers, and *natural* by foreign writers. There seems no objection to the former name, though the logarithms actually invented by Napier depended on the base e^{-1}, but it should be mentioned in text-books that so-called Napierian logarithms are not identical with those originally devised and calculated by Napier.

Tables to convert Briggian into Hyperbolic Logarithms, and vice versa.—Such tables merely consist of the first hundred (sometimes only the first ten) multiples of the modulus ·43429 44819 . . . and its reciprocal 2·30258 50929 . . . to 5, 6, 8, 10, or more places. They are generally to be found in collections of logarithmic tables, but rarely exceed a page in extent, and are very easy to construct. Schrön and Bruhns both give the first hundred multiples of the modulus and its reciprocal to 10 places, and Bremiker (in his edition of Vega and in his six-figure tables) and Dupuis to 7 places. C. F. Degen, *Tabularum Enneas* (Copenhagen, 1824), gives the first hundred multiples of the modulus to 30 places.

Antilogarithms.—In the ordinary tables of logarithms the natural numbers are integers, while the logarithms are incommensurable. In an antilogarithmic canon the logarithms are exact quantities, such as ·00001, ·00002, &c., and the corresponding numbers are incommensurable. The largest and earliest work of this kind is J. Dodson's *Antilogarithmic Canon* (London, 1742), which gives numbers to 11 places corresponding to logarithms from 0 to 1 at intervals of ·00001, arranged like a seven-figure logarithmic table, with interscript differences and proportional parts at the bottom of the page. This work was the only large antilogarithmic canon for more than a century, till in 1844 Shortrede published the first edition of his tables; in 1849 he published the second edition, and in the same year Filipowski's tables appeared. Both these works contain seven-figure antilogarithms: Shortrede gives numbers to logarithms from 0 to 1 at intervals of ·00001, with differences and multiples at the top of the page, and H. E. Filipowski, *A Table of Antilogarithms* (London, 1849), contains a table of the same extent, the proportional parts being given to hundredths.

Small tables of antilogarithms to 20 places occur in several collections of tables, as Gardiner (1742), Callet, and Hutton. Four- and five-place tables are not uncommon in recent works, as *e.g.* in Houël (1871), Gamborg (1897), Schubert (1896), Holman (1896).

Addition and Subtraction, or Gaussian Logarithms.—The object of such tables is to give log $(a \pm b)$ by only one entry when log a and log b are given. Let

$$A = \log x,\ B = \log(1+x^{-1}),\ C = \log(1+x).$$

Leaving out the specimen table in Z. Leonelli's *Théorie des logarithmes additionnels et déductifs* (Bordeaux, 1803), in which the first suggestion was made,[1] the principal tables are the following: Gauss, in Zach's *Monatliche Correspondenz* (1812), gives B and C for argument A from 0 to 2 at intervals of ·001, thence to 3·40

[1] Leonelli's original work of 1803, which is extremely scarce, was reprinted by J. Houël at Paris in 1875.

at intervals of ·01, and to 5 at intervals of ·1, all to 5 places. This table is reprinted in Gauss's *Werke*, vol. iii. p. 244. E. A. Matthiessen, *Tafel zur bequemern Berechnung* (Altona, 1818), gives B and C to 7 places for argument A from 0 to 2 at intervals of ·0001, thence to 3 at intervals of ·001, to 4 at intervals of ·01, and to 5 at intervals of ·1; the table is not conveniently arranged. Peter Gray, *Tables and Formulae* (London, 1849, and "Addendum," 1870), gives C for argument A from -3 to -1 at intervals of ·001 and from -1 to 2 at intervals of ·0001, to 6 places, with proportional parts to hundredths, and log $(1-x)$ for argument A from -3 to -1 at intervals of ·001 and from $\bar{1}$ to $\bar{1}$8999 at intervals of ·0001, to 6 places, with proportional parts. J. Zech, *Tafeln der Additions- und Subtractions-Logarithmen* (Leipzig, 1849), gives B for argument A from 0 to 2 at intervals of ·0001, thence to 4 at intervals of ·001 and to 6 at intervals of ·01; also C for argument A from 0 to ·0003 at intervals of ·0000001, thence to ·05 at intervals of ·000001 and to ·303 at intervals of ·00001, all to 7 places, with proportional parts. These tables are reprinted from Hülsse's edition of Vega (1849); the 1840 edition of Hülsse's Vega contained a reprint of Gauss's original table. T. Wittstein, *Logarithmes de Gauss à sept décimales* (Hanover, 1866), gives B for argument A from 3 to 4 at intervals of ·1, from 4 to 6 at intervals of ·01, from 6 to 8 at intervals of ·001, from 8 to 10 at intervals of ·0001, also from 0 to 4 at the same intervals. In this handsome work the arrangement is similar to that in a seven-figure logarithmic table. Gauss's original five-place table was reprinted in Pasquich, *Tabulae* (Leipzig, 1817); Köhler, *Jerome de la Lande's Tafeln* (Leipzig, 1832), and *Handbuch* (Leipzig, 1848); and Galbraith and Haughton, *Manual* (London, 1860). Houël, *Tables de logarithmes* (1871), also gives a small five-place table of Gaussian logarithms, the addition and subtraction logarithms being separated as in Zech. Modified Gaussian logarithms are given by J. H. T. Müller, *Vierstellige Logarithmen* (Gotha, 1844), viz., a four-place table of B and $-\log(1-x^{-1})$ from $A=0$ to ·03 at intervals of ·0001, thence to ·23 at intervals of ·001, to 2 at intervals of ·01, and to 4 at intervals of ·1; and by Shortrede, *Logarithmic Tables* (vol. i., 1849), viz., a five-place table of B and $\log(1+x)$ from $A=5$ to 3 at intervals of ·1, from $A=\bar{3}$ to $\bar{2}$·7 at intervals of ·01, to 1·3 at intervals of ·001, to 3 at intervals of ·01, and to 5 at intervals of ·1. Filipowski's *Antilogarithms* (1849) contains Gaussian logarithms arranged in a new way. The principal table gives log $(x+1)$ as tabular result for log x as argument from 8 to 14 at intervals of ·001 to 5 places. Weidenbach, *Tafel um den Logarithmen* . . . (Copenhagen, 1829), gives $\log\frac{x+1}{x-1}$ for argument A from ·382 to 2·002 at intervals of ·001, to 3·6 at intervals of ·01, and to 5·5 at intervals of ·1 to 5 places. J. Houël's *Recueil de formules et de tables numériques* (2nd ed., Paris, 1868) contains tables of $\log_{10}(x+1)$, $\log_{10}\frac{1}{1-x}$, and $\log_{10}\frac{1+x}{1-x}$ from $\log x = -5$ to -3 at intervals of ·1, from $\log x = -3$ to -1 at intervals of ·01, from $\log x = -1$ to 0 at intervals of ·001. F. W. Rex (*Fünfstellige Logarithmen-Tafeln*, Stuttgart, 1884) gives also a five-figure table of $\log\frac{1+x}{1-x}$, and E. Hammer in his *Sechsstellige Tafel der Werthe für jeden Wert des Arguments log x* (Leipzig, 1902) gives a six-figure table of this function from $\log x=\bar{7}$ to $\bar{1}$·99000, and thence to 1·999700 to 5 places. S. Gundelfinger's *Sechsstellige Gaussische und siebenstellige gemeine Logarithmen* (Leipzig, 1902) contains a table of $\log_{10}(1+x)$ to 6 places from $\log x = -2$ to 2 at intervals of ·001. G. W. Jones's *Logarithmic Tables* (4th ed., London, and Ithaca, N.Y., 1893) contain 17 pages of Gaussian six-figure tables; the principal of which give $\log(1+x)$ to argument log x from $\log x = -2$ ·80 to 0 at intervals of ·001, and thence to ·1999 at intervals of ·0001, and $\log(1-x^{-1})$ to argument log x from log $x=$·4 to ·5 at intervals of ·0001, and thence to 2·8 at intervals of ·001. Gaussian logarithms to 5 or 4 places occur in many collections of five-figure or four-figure tables.

Quadratic Logarithms.—In a pamphlet *Saggio di tavole dei logaritmi quadratici* (Udine, 1885) Conte A. di Prampero has described a method of obtaining fractional powers (positive or negative) of any number by means of tables contained in the work. If

$$a^{b^x}=\mathrm{N},\ \text{then}\ x=\frac{\log\log \mathrm{N}-\log\log a}{\log b},$$

and if the logarithms are taken to be Briggian and $a=10^{\frac{1}{1024}}$ and $b=2$, then $x=\log_{10}\log_{10}N/\log 2+10$.

This quantity the author defines as the quadratic logarithm of N and denotes by $\mathrm{L_q}N$. It follows from this definition that $\mathrm{L_q}N^r=\mathrm{L_q}N+\log_{10}r/\log_{10}2$. Thus the quadratic logarithms of N and N^s where s is any power (positive or negative) of 2 have the same mantissa.

A subsidiary table contains the values of the constant $\log_{10}r/\log_{10}2$ for 204 fractional values of r. The main table contains the values of 1000 mantissae corresponding to arguments N, $N^{\frac{1}{2}}$, $N^{\frac{1}{4}}$, . . . (which all have the same mantissae). Among the arguments are the quantities 10·0, 10·1, 10·2, . . . 99·9 (the interval being ·1) and 10·00, 10·01, . . . 10·99 (the interval being ·01). As an example, to obtain the value of $12^{\frac{2}{3}}$ we take from the first table the constant -0·584962, which belongs to $\frac{2}{3}$, and entering the main table with 12 we take out the quadratic logarithm 10·109937 which, by applying the constant, gives 9·524975 the quadratic logarithm of the quantity required.

An appendix (*Tavola degli esponenti*) gives the Briggian logarithms of the first 57 numbers to the first 50 numbers as base, viz. $\log_x N$ for $N=2, 3, \ldots, 57$ and $x=2, 3, \ldots, 50$. The results are generally given to 6 places.

Logistic and Proportional Logarithms.—In most collections of tables of logarithms a five-place table of logistic logarithms for every second to 1° is given. Logistic tables give log 3600 − log x at intervals of a second, x being expressed in degrees, minutes, and seconds. In Schulze (1778) and Vega (1797) the table extends to $x=3600''$ and in Callet and Hutton to $x=5280''$. Proportional logarithms for every second to 3° (*i.e.* log 10,800 − log x) form part of nearly all collections of tables relating to navigation, generally to 4 places, sometimes to 5. Bagay, *Tables* (1829), gives a five-place table, but such are not often to be found in collections of mathematical tables. The same remark applies to tables of proportional logarithms for every minute to 24^{h}, which give to 4 or 5 places the values of log 1440 − log x. The object of a proportional or logistic table, or a table of log a − log x, is to facilitate the calculation of proportions in which the third term is a.

Interpolation Tables.—All tables of proportional parts may be regarded as interpolation tables. C. Bremiker, *Tafel der Proportionalteile* (Berlin, 1843), gives proportional parts to hundredths of all numbers from 70 to 699. Schrön, *Logarithms*, contains an interpolation table giving the first hundred multiples of all numbers from 40 to 410. Sexagesimal tables, already described, are interpolation tables where the denominator is 60 or 600. Tables of the values of binomial theorem coefficients, which are required when second and higher orders of differences are used, are described below. W. S. B. Woolhouse, *On Interpolation, Summation, and the Adjustment of Numerical Tables* (London, 1865), contains nine pages of interpolation tables. The book consists of papers extracted from vols. 11 and 12 of the *Assurance Magazine*.

Dual Logarithms.—This term was used by Oliver Byrne in his *Dual Arithmetic*, *Young Dual Arithmetician*, *Tables of Dual Logarithms*, &c. (London, 1863–67). A dual number of the ascending branch is a continued product of powers of 1·1, 1·01, 1·001, &c., taken in order, the powers only being expressed; thus ↓ 6,9,7,8 denotes $(1{\cdot}1)^6(1{\cdot}01)^9(1{\cdot}001)^7(1{\cdot}0001)^8$, the numbers following the ↓ being called dual digits. A dual number which has all but the last digit zeros is called a dual logarithm; the author uses dual logarithms in which there are seven ciphers between the ↓ and the logarithm. Thus since 1·00601502 is equal to ↓ 0,0,0,0,0,0,0,599702 the whole number 599702 is the dual logarithm of the natural number 1·00601502.

A dual number of the descending branch is a continued product of powers of ·9, ·99, &c.: for instance, $({\cdot}9)^3({\cdot}99)^2$ is denoted by '3 '2 ↑. The *Tables*, which occupy 112 pages, give dual numbers and logarithms, both of the ascending and descending branches, and the corresponding natural numbers. The author claimed that his tables were superior to those of common logarithms.

Constants.—In nearly all tables of logarithms there is a page devoted to certain frequently used constants and their logarithms, such as π, π^{-1}, π^2, $\sqrt{\pi}$. A specially good collection is printed in W. Templeton's *Millwright's and Engineer's Pocket Companion* (corrected by S. Maynard, London, 1871), which gives 58 constants involving π and their logarithms, generally to 30 places, and 13 others that may be properly called mathematical. A good list of constants involving π is given in Salomon (1827). A paper by G. Paucker in *Grunert's Archiv* (vol. i. p. 9) has a number of constants involving π given to a great many places, and Gauss's memoir on the lemniscate function (*Werke*, vol. iii.) has $e^{-\pi}$, $e^{-\frac{1}{2}\pi}$, $e^{-\frac{1}{4}\pi}$, &c., calculated to about 50 places. The quantity π has been worked out to 707 places (Shanks, *Proc. Roy. Soc.*, 21, p. 319).

J. C. Adams has calculated Euler's constant to 263 places (*Proc. Roy. Soc.*, 27, p. 88) and the modulus ·43429 . . . to 272 places (*Id.* 42, p. 22). The latter value is quoted in *extenso* under LOGARITHM. J. Burgess on p. 23 of his paper of 1888, referred to under *Tables of e^x*, has given a number of constants involving π and ρ (the constant ·476936 . . . occurring in the *Theory of Errors*), and their Briggian logarithms, to 23 places.

Tables for the Solution of Cubic Equations.—Lambert, *Supplementa* (1798), gives $\pm(x-x^3)$ from $x=$·001 to 1·155 as intervals of ·001 to 7 places, and Barlow (1814) gives x^3-x from $x=1$ to 1·1549 at intervals of ·0001 to 8 places. Very extensive tables for the solution of cubic equations are contained in a memoir "Beiträge zur Auflösung höherer Gleichungen" by J. P. Kulik in the *Abh. der k. Böhm. Ges. der Wiss.* (Prague, 1860), 11, pp. 1–123. The principal tables (pp. 58–123) give to 7 (or 6) places the values of $\pm(x-x^3)$ from $x=0$ to $x=3{\cdot}2800$ at intervals of ·001. There are also tables of the even and uneven determinants of cubic equations, &c. Other tables for the solution of equations are by A. S. Guldberg in the *Forhand.* of the *Videns-Selskab* of Christiania for 1871 and 1872 (equations of the 3rd and 5th order), by S. Gundelfinger, *Tafeln zur Berechnung der reellen Wurzeln sämtlicher trinomischen Gleichungen* (Leipzig, 1897), which depend on the use of Gaussian logarithms, and by R. Mehme, *Schlömilch's Zeitschrift*, 1898, 43, p. 80 (quadratic equations).

Binomial Theorem Coefficients.—Tables of the values of

$$\frac{x(x-1)}{1.2},\ \frac{x(x-1)(x-2)}{1.2.3},\ldots\frac{x(x-1)\ldots(x-5)}{1.2\ldots6}$$

from $x=\cdot01$ to $x=1$ at intervals of ·01 to 7 places (which are useful in interpolation by second and higher orders of differences), occur in Schulze (1778), Barlow (1814), Vega (1797 and succeeding editions), Hantschl (1827), and Köhler (1848). W. Rouse, *Doctrine of Chances* (London, n.d.), gives on a folding sheet $(a+b)^n$ for $n=1, 2,\ldots 20$.

H. Gyldén (*Recueil des Tables*, Stockholm, 1880) gives binomial coefficients to $n=40$ and their logarithms to 7 places. Lambert, *Supplementa* (1798), has the coefficients of the first 16 terms in $(1+x)^{\frac{1}{2}}$ and $(1-x)^{\frac{1}{2}}$, their values being given accurately as decimals. Vega (1797) has a page of tables giving $\frac{1}{2.4}, \frac{1.3}{2.4.6},\ldots\frac{1}{2.3},\ldots$ and similar quantities to 10 places, with their logarithms to 7 places, and a page of this kind occurs in other collections. Köhler (1848) gives the values of 40 such quantities.

Figurate Numbers.—Denoting $n(n+1)\ldots(n+i-1)/i!$ by $[n]_i$, Lambert, *Supplementa*, 1798, gives $[n]_i$ from $n=1$ to $n=30$ and from $i=1$ to $i=12$; and G. W. Hill (*Amer. Jour. Math.*, 1884, 6, p. 130) gives $\log_{10}[n]_i$ for $n=\frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \frac{7}{2}, \frac{9}{2}$, and from $i=1$ to $i=30$.

Trigonometrical Quadratic Surds.—The surd values of the sines of every third degree of the quadrant are given in some tables of logarithms; *e.g.*, in Hutton's (p. xxxix., ed. 1855), we find $\sin 3^\circ=\frac{1}{8}\{\sqrt{(5+\sqrt5)}+\sqrt{\tfrac{15}{2}}+\sqrt{\tfrac{5}{2}}-\sqrt{(15+3\sqrt5)}-\sqrt{\tfrac{3}{2}}-\sqrt{\tfrac{1}{2}}\}$; and the numerical values of the surds $\sqrt{(5+\sqrt5)}$, $\sqrt{(\frac{15}{2})}$, &c., are given to 10 places. These values were extended to 20 places by Peter Gray, *Mess. of Math.*, 1877, 6, p. 105.

Circulating Decimals.—Goodwyn's tables have been described already. Several others have been published giving the numbers of digits in the periods of the reciprocals of primes: Burckhardt, *Tables des diviseurs du premier million* (Paris, 1814–1817), gave one for all primes up to 2543 and for 22 primes exceeding that limit. E. Desmarest, *Théorie des nombres* (Paris, 1852), included all primes up to 10,000. C. G. Reuschle, *Mathematische Abhandlung, enthaltend neue zahlentheoretische Tabellen* (1856), contains a similar table to 15,000. This W. Shanks extended to 60,000; the portion from 1 to 30,000 is printed in the *Proc. Roy. Soc.*, 22, p. 200, and the remainder is preserved in the archives of the society (*Id.*, 23, p. 260 and 24, p. 392). The number of digits in the decimal period of $1/p$, is the same as the exponent to which 10 belongs for modulus p, so that, whenever the period has $p-1$ digits, 10 is a primitive root of p. Tables of primes having a given number, n, of digits in their periods, *i.e.* tables of the resolutions of 10^n-1 into factors and, as far as known, into prime factors, have been given by W. Looff (in *Grunert's Archiv*, 16, p. 54; reprinted in *Nouv. annales*, 14, p. 115) and by Shanks (*Proc. Roy. Soc.*, 22, p. 381). The former extends to $n=60$ and the latter to $n=100$, but there are gaps in both. Reuschle's tract also contains resolutions of 10^n-1.

There is a similar table by C. E. Bickmore in *Mess. of Math.*, 1896, 25, p. 43. A full account of all tables connecting n and p where $10^n=1$, mod p, 10^n being the least power for which this congruence holds good, is given by Allan Cunningham (*Id.*, 1904, 33, p. 145). The paper by the same author, "Period-lengths of Circulates" (*Id.* 1900, 29, p. 145) relates to circulators in the scale of radix a. See also tables of the resolutions of a^n-1 into factors under *Tables relating to the Theory of Numbers* (below). Some further references on circulating decimals are given in *Proc. Camb. Phil. Soc.*, 1878, 3, p. 185.

Pythagorean Triangles.—Right-angled triangles in which the sides and hypothenuse are all rational integers are frequently termed Pythagorean triangles, as, for example, the triangles 3, 4, 5, and 5, 12, 13. Schulze, *Sammlung* (1778), contains a table of such triangles subject to the condition $\tan\frac{1}{2}\omega > \frac{1}{25}$($\omega$ being one of the acute angles). About 100 triangles are given, but some occur twice. Large tables of right-angled rational triangles were given by C. A. Bretschneider, in *Grunert's Archiv*, 1841, 1, p. 96, and by Sang, *Trans. Roy. Soc. Edin.*, 1864, 33, p. 727. In these tables the triangles are arranged according to hypothenuses and extend to 1201, 1200, 49, and 1105, 1073, 264 respectively. W. A. Whitworth, in a paper read before the Lit. and Phil. Society of Liverpool in 1875, carried his list as far as 2465, 2337, 784. See also H. Rath, "Die rationalen Dreiecke," in *Grunert's Archiv*, 1874, 56, p. 188. Sang's paper also contains a table of triangles having an angle of 120° and their sides integers.

Powers of π.—G. Paucker, in *Grunert's Archiv*, p. 10, gives π^{-1} and $\pi^{\frac{1}{2}}$ to 140 places, and $\pi^{-2}, \pi^{-\frac{1}{2}}, \pi^{\frac{1}{3}}, \pi^{\frac{2}{3}}$ to about 50 places; J. Burgess (*Trans. Roy. Soc. Edin.*, 1898, 39, II., No. 9, p. 23) gives $(\frac{1}{2}\pi)^{-\frac{1}{2}}$, $2^{\frac{1}{2}}\pi^{-\frac{1}{2}}$, and some other constants involving π as well as their Briggian logarithms to 23 places, and in Maynard's list of constants (see *Constants*, above) π^2 is given to 31 places. The first twelve powers of π and π^{-1} to 22 or more places were given by Glaisher, in *Proc. Lond. Math. Soc.*, 8, p. 140, and the first hundred multiples of π and π^{-1} to 12 places by J. P. Kulik, *Tafel der Quadrat- und Kubik-Zahlen* (Leipzig, 1848).

The Series $1^{-n}+2^{-n}+3^{-n}+$&c.—Let S_n, s_n, σ_n denote respectively the sums of the series $1^{-n}+2^{-n}+3^{-n}+$ &c., $1^{-n}-2^{-n}+3^{-n}-$&c., $1^{-n}+3^{-n}+5^{-n}+$ &c. Legendre (*Traité des fonctions elliptiques*, vol. 2, p. 432) computed S_n to 16 places from $n=1$ to 35, and Glaisher (*Proc. Lond. Math. Soc.*, 4, p. 48) deduced s_n and σ_n for the same arguments and to the same number of places. The latter also gave S_n, s_n, σ_n for $n=2, 4, 6,\ldots 12$ to 22 or more places (*Proc. Lond. Math. Soc.*, 8, p. 140), and the values of Σ_n, where $\Sigma_n=2^{-n}+3^{-n}+5^{-n}+$&c. (prime numbers only involved), for $n=2, 4, 6, \ldots 36$ to 15 places (*Compte rendu de l'Assoc. Française*, 1878, p. 172).

C. W. Merrifield (*Proc. Roy. Soc.*, 1881, 33, p. 4) gave the values of $\log_e S_n$ and Σ_n for $n=1,2,3,\ldots, 35$ to 15 places, and Glaisher (*Quar. Jour. Math.*, 1891, 25, p. 347) gave the values of the same quantities for $n=2,4,6,\ldots, 80$ to 24 places (last figure uncertain). Merrifield's table was reprinted by J. P. Gram on p. 269 of the paper of 1884, referred to under *Sine-integral, &c.*, who also added the values of $\log_{10} S_n$ for the same arguments to 15 places. An error in Σ_8 in Merrifield's table is pointed out in *Quar. Jour. Math.*, 25, p. 373. This quantity is correctly given in Gram's reprint. T. J. Stieljes has greatly extended Legendre's table of S_n. His table (*Acta math.*, 1887, 10, p. 299) gives S_n for all values of n up to $n=70$ to 32 places. Except for six errors of a unit in the last figure he found Legendre's table to be correct. Legendre's table was reprinted in De Morgan's *Diff. and Int. Calc.* (1842), p. 554. Various small tables of other series, involving inverse powers of prime numbers, such as $3^{-n}-5^{-n}+7^{-n}+11^{n}-13^{n}+\ldots$, are given in vols. 25 and 26 of the *Quar. Jour. Math.*

Tables of e^x and e^{-x}, or Hyperbolic Antilogarithms.—The largest tables are the following: C. Gudermann, *Theorie der potenzial- oder cyklisch-hyperbolischen Functionen* (Berlin, 1833), which consists of papers reprinted from vols. 8 and 9 of *Crelle's Journal*, and gives $\log_{10}\sinh x$, $\log_{10}\cosh x$, and $\log_{10}\tanh x$ from $x=2$ to 5 at intervals of ·001 to 9 places and from $x=5$ to 12 at intervals of ·01 to 10 places. Since $\sinh x=\frac{1}{2}(e^x-e^{-x})$ and $\cosh x=\frac{1}{2}(e^x+e^{-x})$, the values of e^x and e^{-x} are deducible at once by addition and subtraction. F. W. Newman, in *Camb. Phil. Trans.*, 13, p. 145, gives values of e^{-x} from $x=0$ to $15\cdot349$ at intervals of ·001 to 12 places, from $x=15\cdot350$ to $17\cdot298$ at intervals of ·002, and from $x=17\cdot300$ to $27\cdot635$ at intervals of ·005, to 14 places. Glaisher, in *Camb. Phil. Trans.*, 13, p. 243, gives four tables of e^x, e^{-x}, $\log_{10}e^x$, $\log_{10}e^{-x}$, their ranges being from $x=\cdot001$ to $\cdot1$ at intervals of ·001, from ·01 to 2 at intervals of ·01, from ·1 to 10 at intervals of ·1, from 1 to 500 at intervals of unity. Vega, *Tabulae* (1797 and later ed.), has $\log_{10}e^x$ to 7 places and e^x to 7 figures from $x=\cdot01$ to 10 at intervals of ·01. Köhler's *Handbuch* contains a small table of e^x. In Schulze's *Sammlung* (1778) e^x is given for $x=1, 2, 3,\ldots$ 24 to 28 or 29 figures and for $x=25$, 30, and 60 to 32 or 33 figures; this table is reprinted in Glaisher's paper (loc. cit.). In Salomon's *Tafeln* (1827) the values of e^n, $e^{\cdot n}$, $e^{\cdot0n}$, $e^{\cdot00n},\ldots$ $e^{\cdot000000n}$, where n has the values $1, 2,\ldots 9$, are given to 12 places. Bretschneider, in *Grunert's Archiv*, 3, p. 33, gave e^x and e^{-x} and also $\sin x$ and $\cos x$ for $x=1, 2,\ldots 10$ to 20 places, and J. P. Gram (in his paper of 1884, referred to under *Sine-integral, &c.*), gives e^x for $x=10, 11,\ldots 20$ to 24 places, and from $x=7$ to $x=20$ at intervals of 0·2 to 10, 13, 14, or 15 places. J. Burgess (*Trans. Roy. Soc. Edin.*, 1888, 39, II. No. 9) has given (p. 26) the values of e^{-x} and $\sqrt{\frac{2}{\pi}}e^{-x}$ for $x=\frac{1}{2}$ and for $x=1, 2,\ldots,$ 10 to 30 places. In the same paper he also gives the values of $\sqrt{\frac{2}{\pi}}e^{-x^2}$ from $x=0$ to $x=1\cdot250$ to 9 places, and from $x=1\cdot25$ to $x=1\cdot50$ at intervals of ·01, and thence at various intervals to $x=6$ to 15 places, and the values of $\log_{10}\sqrt{\frac{2}{\pi}}e^{-x^2}$ from $x=1$ tc $x=3$ at intervals of ·001 to 16 places.

Factorials.—The values of $\log_{10}(n!)$, where $n!$ denotes $1\,.\,2\,.\,3\ldots n$, from $n=1$ to 1200 to 18 places, are given by C. F. Degen, *Tabularum Enneas* (Copenhagen, 1824), and reprinted, to 6 places, at the end of De Morgan's article "Probabilities" in the *Encyclopaedia Metropolitana*. Shortrede, *Tables* (1849, vol. i.), gives $\log(n!)$ to $n=1000$ to 5 places, and for the arguments ending in 0 to 8 places. Degen also gives the complements of the logarithms. The first 20 figures of the values of $n\times n!$ and the values of $-\log(n\times n!)$ to 10 places are given by Glaisher as far as $n=71$ in the *Phil. Trans.* for 1870 (p. 370), and the values of $1/n!$ to 28 significant figures as far as $n=50$ in *Camb. Phil. Trans.*, 13, p. 246.

Bernoullian Numbers.—The first fifteen Bernoullian numbers were given by Euler, *Inst. Calc. Diff.*, part ii. ch. v. Sixteen more were calculated by Rothe, and the first thirty-one were published by M. Ohm in *Crelle's Journal*, 20, p. 11. J. C. Adams calculated the next thirty-one, and a table of the first sixty-two was published by him in the *Brit. Ass. Report* for 1877 and in *Crelle's Journal*, 85, p. 269. In the *Brit. Ass. Report* the numbers are given not only as vulgar fractions, but also expressed in integers and circulating decimals. The first nine figures of the values of the first 250 Bernoullian numbers, and their Briggian logarithms to 10 places, have been published by Glaisher, *Camb. Phil. Trans.*, 12, p. 384.

Tables of log tan $(\frac{1}{4}\pi+\frac{1}{2}\phi)$.—C. Gudermann, *Theorie der potenzial- oder cyklisch-hyperbolischen Functionen* (Berlin, 1833), gives (in 100 pages) $\log\tan(\frac{1}{4}\pi+\frac{1}{2}\phi)$ for every centesimal minute of the quadrant to 7 places. Another table contains the values of this function, also at intervals of a minute, from 88° to 100° (centesimal) to 11 places. A. M. Legendre, *Traité des fonctions elliptiques* (vol. ii. p. 256), gives the same function for every half degree (sexagesimal) of the quadrant to 12 places.

The Gamma Function.—Legendre's great table appeared in vol. ii. of his *Exercices de calcul intégral* (1816), p. 85, and in vol. ii. of his *Traité des fonctions elliptiques* (1826), p. 489. $\log_{10}\Gamma(x)$ is given from $x=1$ to 2 at intervals of ·001 to 12 places, with differences to the third order. This table is reprinted in full in O. Schlömilch, *Analytische Studien* (1848), p. 183; an abridgment in which the arguments differ by ·01 is given by De Morgan, *Diff. and Int. Calc.*, p. 587. The last figures of the values omitted are also supplied, so that the full table can be reproduced. A seven-place abridgment (without differences) is published in J. Bertrand, *Calcul intégral* (1870), p. 285, and a six-figure abridgment in B. Williamson, *Integral Calculus* (1884), p. 169. In vol. i. of his *Exercices* (1811), Legendre had previously published a seven-place table of $\log_{10}\Gamma(x)$, without differences.

Tables connected with Elliptic Functions.—Legendre published elaborate tables of the elliptic integrals in vol. ii. of his *Traité des fonctions elliptiques* (1826). Denoting the modular angle by θ, the amplitude by ϕ, the incomplete integral of the first and second kind by $F(\phi)$ and $F_1(\phi)$, and the complete integrals by K and E, the tables are:—(1) $\log_{10}E$ and $\log_{10}K$ from $\theta=0°$ to 90° at intervals of 0°·1 to 12 or 14 places, with differences to the third order; (2) $E_1(\phi)$ and $F(\phi)$, the modular angle being 45°, from $\phi=0°$ to 90° at intervals of 0°·5 to 12 places, with differences to the fifth order; (3) $E_1(45°)$ and $F(45°)$ from $\theta=0°$ to 90° at intervals of 1°, with differences to the sixth order, also E and K for the same arguments, all to 12 places; (4) $E_1(\phi)$ and $F(\phi)$ for every degree of both the amplitude and the argument to 9 or 10 places. The first three tables had been published previously in vol. iii. of the *Exercices de calcul intégral* (1816).

Tables involving q.—P. F. Verhulst, *Traité des fonctions elliptiques* (Brussels, 1841), contains a table of $\log_{10}(\log_{10})q^{-1}$ for argument θ at intervals of 0°·1 to 12 or 14 places. C. G. J. Jacobi, in *Crelle's Journal*, 26, p. 93, gives $\log_{10} q$ from $\theta=0°$ to 90° at intervals of 0°·1 to 5 places. E. D. F. Meissel's *Sammlung mathematischer Tafeln*, i. (Iserlohn, 1860), consists of a table of $\log_{10} q$ at intervals of 1′ from $\theta=0°$ to 90° to 8 places. Glaisher, in *Month. Not. R.A.S.*, 1877, 37, p. 372, gives $\log_{10} q$ to 10 places and q to 9 places for every degree. In J. Bertrand's *Calcul Intégral* (1870), a table of $\log_{10} q$ from $\theta=0°$ to 90° at intervals of 5′ to 5 places is accompanied by tables of $\log_{10}\sqrt{(2K/\pi)}$ and $\log_{10}\log_{10} q^{-1}$ and by abridgments of Legendre's tables of the elliptic integrals. O. Schlömilch, *Vorlesungen der höheren Analysis* (Brunswick, 1879), p. 448, gives a small table of $\log_{10} q$ for every degree to 5 places.

Legendrian Coefficients (Zonal Harmonies).—The values of $P^n(x)$ for $n=1, 2, 3, \dots 7$ from $x=0$ to 1 at intervals of ·01 are given by Glaisher, in *Brit. Ass. Rep.*, 1879, pp. 54–57. The functions tabulated are $P^1(x)=x$, $P^2(x)=\frac{1}{2}(3x^2-1)$, $P^3(x)=\frac{1}{2}(5x^3-3x)$, $P^4(x)=\frac{1}{8}(35x^4-30x^2+3)$, $P^5(x)=\frac{1}{8}(63x^5-70x^3+15x)$, $P^6(x)=\frac{1}{16}(231x^6-315x^4+105x^2-5)$, $P^7(x)=\frac{1}{16}(429x^7-693x^5+315x^3-35x)$.

The values of $P^n(\cos\theta)$ for $n=1, 2, \dots 7$ for $\theta=0°, 1°, 2°, \dots 90°$ to 4 places are given by J. Perry in the *Proc. Phys. Soc.*, 1892, 11, p. 221, and in the *Phil. Mag.*, 1891, ser. 6, 32, p. 512. The functions P^n occur in connexion with the theory of interpolation, the attraction of spheroids, and other physical theories.

Bessel's Functions.—F. W. Bessel's original table appeared at the end of his memoir, "Untersuchung des planetarischen Teils der Störungen, welche aus der Bewegung der Sonne entstehen" (in *Abh. d. Berl. Akad.* 1824; reprinted in vol. i. of his *Abhandlungen*, p. 84). It gives $J_0(x)$ and $J_1(x)$ from $x=0$ to 3·2 at intervals of ·01. More extensive tables were calculated by P. A. Hansen in "Ermittelung der absoluten Störungen in Ellipsen von beliebiger Excentricität und Neigung" (in *Schriften der Sternwarte Seeberg*, part i., Gotha, 1843). They include an extension of Bessel's original table to $x=20$, besides smaller tables of $J_n(x)$ for certain values of n as far as $n=28$, all to 7 places. Hansen's table was reproduced by O. Schlömilch, in *Zeitschr. für Math.*, 2, p. 158, and by E. Lommel, *Studien über die Bessel'schen Functionen* (Leipzig, 1868), p. 127. Hansen's notation is slightly different from Bessel's; the change amounts to halving each argument. Schlömilch gives the table in Hansen's form; Lommel expresses it in Bessel's.

Lord Rayleigh's *Theory of Sound* (1894), 1, p. 321, gives $J_0(x)$ and $J_1(x)$ from $x=0$ to $x=13·4$ at intervals of 0·1 to 4 places, taken from Lommel. A large table of the same functions was given by E. D. F. Meissel in the *Abh. d. Berlin Akad.* for 1888 (published also separately). It contains the values of $J_0(x)$ and $J_1(x)$ from $x=0$ to $x=15·50$ at intervals of ·01. A. Lodge has calculated the values of the function $I_n(x)$ where

$$I_n(x)=i^{-n}J_n(ix)=\frac{x^n}{2^n n!}\left\{1+\frac{x^2}{2(2n+2)}+\frac{x^4}{2\cdot4\cdot(2n+2)(2n+4)}+\dots\right\}$$

His tables give $I_n(x)$ for $n=0, 1, 2, \dots, 11$ from $x=0$ to $x=6$ at intervals of 0·2 to 11 or 12 places (*Brit. Ass. Rep.*, 1889, p. 29), $I_1(x)$ and $I_0(x)$ from $x=0$ to $x=5·100$ at intervals of ·001 to 9 places (*Id.*, 1893, p. 229, and 1896, p. 99), and of $J_0(x\sqrt{i})$ from $x=0$ to $x=6$ at intervals of 0·2 (*Id.*, 1893, p. 228) to 9 places. In all the tables the last figure is uncertain. Subsidiary tables for the calculation of Bessel's functions are given by L. N. G. Filon and A. Lodge in *Brit. Ass. Rep.*, 1907, p. 94. The work is being continued, the object being to obtain the values of $J_n(x)$ for $n=0, \frac{1}{2}, 1, 1\frac{1}{2}, \dots, 6\frac{1}{2}$. A table by E. Jahnke has been announced, which, besides tables of other mathematical functions, is to contain values of Bessel's functions of order $\frac{1}{2}$ and roots of functions derived from Bessel's functions.

Sine, Cosine, Exponential, and Logarithm Integrals.—The functions so named are the integrals $\int_0^x \frac{\sin x}{x}dx$, $\int_\infty^x \frac{\cos x}{x}dx$, $\int_{-\infty}^x \frac{e^x}{x}dx$, $\int_0^x \frac{dx}{\log x}$, which are denoted by the functional signs Si x, Ci x, Ei x, li x respectively, so that Ei $x=$ li e^x. J. von Soldner, *Théorie et tables d'une nouvelle fonction transcendante* (Munich, 1809), gave the values of li x from $x=0$ to 1 at intervals of ·1 to 7 places, and thence at various intervals to 1220 to 5 or more places. This table is reprinted in De Morgan's *Diff. and Int. Calc.*, p. 662. Bretschneider, in *Grunert's Archiv*, 3, p. 33, calculated Ei $(\pm x)$, Si x, Ci x for $x=1, 2, \dots 10$ to 20 places, and subsequently (in Schlömilch's *Zeitschrift*, 6) worked out the values of the same functions from $x=0$ to 1 at intervals of ·01 and from 1 to 7·5 at intervals of ·1 to 10 places. Two tracts by L. Stenberg, *Tabulae logarithmi integralis* (Malmö, part i. 1861 and part ii. 1867), give the values of li 10^x from $x=-15$ to 3·5 at intervals of ·01 to 18 places. Glaisher, in *Phil. Trans.*, 1870, p. 367, gives Ei $(\pm x)$, Si x, Ci x from $x=0$ to 1 at intervals of ·01 to 18 places, from $x=1$ to 5 at intervals of ·1 and thence to 15 at intervals of unity, and for $x=20$ to 11 places, besides seven-place tables of Si x and Ci x and tables of their maximum and minimum values. See also Bellavitis, "Tavole numeriche logaritmo-integrale" (a paper in *Memoirs of the Venetian Institute*, 1874). F. W. Bessel calculated the values of li 1000, li 10,000, li 100,000, li 200,000, . . . li 600,000, and li 1,000,000 (see *Abhandlungen*, 2, p. 339). In Glaisher, *Factor Table for the Sixth Million* (1883), § iii., the values of li x are given from $x=0$ to 9,000,000 at intervals of 50,000 to the nearest integer. J. P. Gram in the publications of the Copenhagen Academy, 1884, 2, No. 6 (pp. 268–272), has given to 20 places the values of Ei x from $x=10$ to $x=20$ at intervals of a unit (thus carrying Bretschneider's table to this extent) and to 8, 9, or 10 places, the values of the same function from $x=5$ to $x=20$ at intervals of 0·2 (thus extending Glaisher's table in the *Phil. Trans.*).

Values of $\int_0^x e^{-x^2}dx$ *and* $e^{x^2}\int_0^x e^{-x^2}dx$.—These functions are employed in researches connected with refractions, theory of errors, conduction of heat, &c. Let $\int_0^x e^{-x^2}dx$ and $\int_x^\infty e^{-x^2}dx$ be denoted by erf x and erfc x respectively, standing for "error function" and "error function complement," so that erf $x+$erfc $x=\frac{1}{2}\sqrt{\pi}$ (*Phil. Mag.*, Dec. 1871; it has since been found convenient to transpose as above the definitions there given of erf and erfc). The tables of the functions, and of the functions multiplied by e^{x^2}, are as follows. C. Kramp, *Analyse des Réfractions* (Strasbourg, 1798), has erfc x from $x=0$ to 3 at intervals of ·01 to 8 or more places, also $\log_{10}$ (erfc x) and $\log_{10}$ (e^{x^2}erfc x) for the same values to 7 places. F. W. Bessel, *Fundamenta astronomiae* (Königsberg, 1818), has $\log_{10}$ (e^{x^2}erfc x) from $x=0$ to 1 at intervals of ·01 to 7 places, likewise for argument $\log_{10} x$, the arguments increasing from 0 to 1 at intervals of ·01. A. M. Legendre, *Traité des fonctions elliptiques* (1826), 2, p. 520, contains $\Gamma(\frac{1}{2}, e-x^2)$, that is, 2 erfc x from $x=0$ to ·5 at intervals of ·01 to 10 places. J. F. Encke, *Berliner ast. Jahrbuch* for 1834, gives $\frac{2}{\sqrt{\pi}}$ erf x from $x=0$ to 2 at intervals of ·01 to 7 places and $\frac{2}{\sqrt{\pi}}$ erf (ρx) from $x=0$ to 3·4 at intervals of ·01 and thence to 5 at intervals of ·1 to 5 places, ρ being ·4769360. Glaisher, in *Phil. Mag.*, December 1871, gives erfc x from $x=3$ to 4·5 at intervals of ·01 to 11, 13, or 14 places. Encke's tables and two of Kramp's were reprinted in the *Encyclopaedia Metropolitana*, art. "Probabilities." These tables have also been reprinted in many foreign works on probabilities, errors of observations, &c. In vol. 2 (1880) of his *Lehrbuch zur Bahnbestimmung der Kometen und Planeten* T. R. v. Oppolzer gives (p. 587) a table of erf x from $x=0$ to 4·52 at intervals of ·01 to 10 places, and (p. 603) a table of $\frac{2}{\sqrt{\pi}}$ erf x from $x=0$ to 2 at intervals of ·01 to 5 places. Both tables were the result of original calculations. A very large table of $\log_{10} e^{x^2}$ erfc x was calculated by R. Radau and published in the *Annales de l'observatoire de Paris* (*Mémoires*, 1888, 18, B. 1–25). It contains the values of $\log_{10} e^{x^2}$ erfc x from $x=-0·120$ to 1·000 at intervals of ·001 to 7 places, with differences. A. Markoff in a separate publication, *Table des valeurs de l'intégrale* $\int_x^\infty e^{-t^2}dt$ (St Petersburg, 1888), gives erfc x from $x=0$ to 3 at intervals of ·001 and from $x=3$ to 4·80 at intervals of ·01, with first, second, and third differences to 11 places. He also gives a table of $\frac{2}{\sqrt{\pi}}$ erf x from $x=0$ to $x=2·499$ at intervals of ·001 and thence to 3·79 at intervals of ·01. J. Burgess, *Trans. Roy. Soc. Edin.*, 1888, 39, II., No. 9, published very extensive tables of $\frac{2}{\sqrt{\pi}}$ erf x, which were entirely the result of a new calculation. His tables give the values of this function from $x=0$ to $1\cdot250$ at intervals of $\cdot001$ to 9 places with first and second differences, from $x=1$ to 3 at intervals of $\cdot001$ to 15 places with differences to the fourth order, and from $x=3$ to 5 at intervals of $\cdot1$ to 15 places. He also gives erfc x from $x=0$ to $x=5$ at intervals of $\cdot1$ to 15 places. B. Kämpfe in Wundt's *Phil. Stud.*, 1893, p. 147, gives $\frac{2}{\sqrt{\pi}}$ erf x from $x=0$ to $x=1\cdot509$ at intervals of $\cdot001$, and from $x=1\cdot50$ to $x=2\cdot88$ at intervals of $\cdot01$ to 4 places. G. T. Fechner's *Elemente der Psychophysik* (Leipzig, 1860) contains (pp. 108, 110) some small four-place tables connecting r/n (as argument) and hD where $\frac{r}{n}=\frac{1}{2}+\frac{1}{\sqrt{\pi}}\mathrm{erf}\,\frac{hD}{2}$. A more detailed account of tables of erf x, e^{x^2} erf x, &c., is given in *Mess. of Math.*, 1908, 38, p. 117.

Values of $\int_0^x e^{x^2}dx$.—The values of this integral have been calculated by H. G. Dawson from $x=0$ to $x=2$ to 7 places (last figure uncertain). The table is published in the *Proc. Lond. Math. Soc.*, 1898, 29, p. 521.

Tables of Integrals, not Numerical.—Meyer Hirsch, *Integraltafeln* (1810; Eng. trans., 1823), and Minding, *Integraltafeln* (Berlin, 1849), give values of indefinite integrals and formulae of reduction; both are useful and valuable works. De Haan, *Nouvelles tables d'intégrales définies* (Leyden, 1867), is a quarto volume of 727 pages containing evaluations of definite integrals, arranged in 485 tables. The first edition appeared in vol. 4 of the *Transactions* of the Amsterdam Academy of Sciences. This edition, though not so full and accurate as the second, gives references to the original memoirs in which the different integrals are considered. B. O. Peirce's *A Short Table of Integrals* (Boston, U.S.A., 1899) contains integrals, formulae, expansions, &c., as well as some four-place numerical tables, including those of hyperbolic sines and cosines and their logarithms.

Tables relating to the Theory of Numbers.—These are of so technical a character and so numerous that a comprehensive account cannot be attempted here. The reader is referred to Cayley's report in the *Brit.Ass. Rep.* for 1875, p. 305, where a full description with references is given. Three tables published before that date may, however, be briefly noticed on account of their importance and because they form separate volumes: (1) C. F. Degen, *Canon Pellianus* (Copenhagen, 1817), relates to the indeterminate equation $y^2-ax^2=1$ for values of a from 1 to 1000. It in fact gives the expression for $\sqrt{a}$ as a continued fraction; (2) C. G. J. Jacobi, *Canon arithmeticus* (Berlin, 1839), is a quarto work containing 240 pages of tables, where we find for each prime up to 1000 the numbers corresponding to given indices and the indices corresponding to given numbers, a certain primitive root (10 is taken whenever it is a primitive root) of the prime being selected as base; (3) C. G. Reuschle, *Tafeln complexer Primzahlen, welche aus Wurzeln der Einheit gebildet sind* (Berlin, 18/5), includes an enormous mass of results relating to the higher complex theories.

Passing now to tables published since the date of Cayley's report, the two most important works are (1) Col. Allan Cunningham's *Binary Canon*, (London, 1900), a quarto volume similar in construction, arrangement, purpose, and extent to Jacobi's *Canon arithmeticus*, but differing from it in using the base 2 throughout, *i.e.* in Jacobi's *Canon* the base of each table is always a primitive root of the modulus, while in Cunningham's it is always 2. The latter tables in fact give the residues R of 2^x (where $x=0, 1, 2, \ldots$) for every prime p or power of a prime, p^x, up to 1000, and also the indices x of 2^x, which yield the residues R to the same moduli. This work contains a list of errors found in the *Canon arithmeticus*. (2) The same author's *Quadratic Partitions* (London, 1904). These tables give for every prime p up to 100,000 the values of a, b; c, d; A, B; and L, M where $p=a^2+b^2=c^2+2d^2=A^2+3B^2=\frac{1}{4}(L^2+27M^2)$. They also give e, f where $p=e^2-2f^2$ up to 25,000 and resolutions of p into the forms x^2-5y^2, $\frac{1}{4}(X^2-5Y^2)$, t^2+7u^2, $\frac{1}{4}(v^2+11w^2)$, $A'^2-3B'^2$, $x'^2+5y'^2$, G^2+6H^2, $G'^2-6H'^2$, $t'^2-7u'^2$, $\xi^2+10\eta^2$, $\xi'^2-10\eta'^2$, $v'^2-11w'^2$ up to 10,000; as well as the least solutions of $\tau^2-Dv^2=\pm1$ up to $D=100$ and least solutions of other similar equations. A complete list of errata in the previous partition tables of Jacobi, Reuschle, Lloyd Tanner, and in this table is given by Allan Cunningham in *Mess. of Math.*, 1904, 34, p. 132. The resolution of a^n-1 into its numerical factors is treated in detail by C. E. Bickmore in *Mess. of Math.*, 1896, 25, p. 1, and 1897, 26, p. 1. On p. 43 of the former volume he gives a table of the known factors of a^n-1 for $a=2, 3, 5, 6, 7, 10, 11, 12$ and from $n=1$ to $n=50$. Other papers on the same subject contained in the same periodical are by Allan Cunningham, 1900, 29, p. 145; 1904, 33, p. 95; and F. B. Escott, *ibid.*, p. 49. These papers contain references to other writings. Tables of the resolutions of 10^n-1 are referred to separately in this article under *Circulating Decimals*. If a^x is the smallest power of a for which the congruence $a^x\equiv1$ (mod. p) is satisfied, then a is said to belong to the exponent x for modulus p, and x may be called the chief exponent (*Haupt-exponent* by Allan Cunningham) of the base a for the modulus p; so that (1) this exponent is the number of figures in the circulating period of the fraction $1/p$ in the scale of radix a, and (2) when $x=p-1$, a is a primitive root of p. In *Mess. of Math.*, 1904, 33, p. 145, Allan Cunningham has given a complete list of Haupt-exponent tables with lists of errata in them; and in *Quar. Jour. Math.*, 1906, 37, p. 122, he gives a table of Haupt-exponents of 2 for all primes up to 10,000. In *Acta Math.* (1893, 17, p. 315; 1897, 20, p. 153; 1899, 22, p. 200) G. Wertheim has given the least primitive root of primes up to 5000. The following papers contain lists of high primes or factorizations of high numbers: Allan Cunningham, *Mess. of Math.*, 1906, 35, p. 166 (Pellian factorizations); 1907, 36, p. 145 (Quartan factorizations); 1908, 37, p. 65 (Trinomial binary factorizations); 1909, 38, pp. 81, 145 (Diophantine factorization of quartans); 1910, 39, pp. 33, 97; 1911, 40, p. 1 (Sextan factorizations); 1902, 31, p. 165; 1905, 34, p. 72 (High primes). The last three are joint papers by Cunningham and H. J. Woodall. Tables relating to the distribution of primes are contained in the introduction to the *Sixth Million* (see under *Factor Tables*), in J. P. Gram's paper on the number of primes inferior to a given limit in the *Vidensk. Selsk. Skr.*, 1884, II. 6, Copenhagen, and in *Mess. of Math.*, 1902, 31, p. 172. A table of $\chi(n)$, the sum of the complex numbers having n for norm, for primes and powers of primes up to $n=13{,}000$ by Glaisher, was published in *Quar. Jour. Math.*, 1885, 20, p. 152, and a seven-place table of $f(x)$ and $\log_{10} f(x)$, where $f(x)$ denotes $\frac{1}{2}\cdot\frac{2}{3}\cdot\frac{4}{5}\cdots\frac{x-1}{x}$, the denominators being the series of prime numbers up to 10,000, in *Mess. of Math.*, 1899, 28, p. 1.

Bibliography.—Bibliographical and historical information relating to tables is collected in *Brit. Ass. Rep.* for 1873, p. 6. The principal works are:—J. C. Heilbronner, *Historia Matheseos* (Leipzig, 1742), the arithmetical portion being at the end, J. E. Scheibel, *Einleitung zur mathematischen Bücherkenntniss* (Breslau, 1771–84); A. G. Kästner, *Geschichte der Mathematik* (Göttingen, 1796–1800), vol. iii.; F. G. A. Murhard, *Bibliotheca Mathematica* (Leipzig, 1797–1804), vol. ii.; J. Rogg, *Bibliotheca Mathematica* (Tübingen, 1830), and continuation from 1830 to 1854 by L. A. Sohnke (Leipzig and London, 1854); J. de Lalande, *Bibliographie astronomique* (Paris, 1803), a separate index on p. 960. A great deal of information upon early tables is given by J. B. J. Delambre, *Histoire de l'astronomie moderne* (Paris, 1821), vol. i.; and in Nos. xix. and xx. of C. Hutton's *Mathematical Tracts* (1812). For lists of logarithmic tables of all kinds see De Haan, *Verslagen en Mededeelingen* of the Amsterdam Academy of Sciences (*Abt. Natuurkunde*) 1862, xiv. 15, and *Verhandelingen* of the same academy, 1875, xv. separately paged.

De Morgan's article "Tables," which appeared first in the *Penny Cyclopaedia*, and afterwards with additions in the *English Cyclopaedia*, gives not only a good deal of bibliographical information, but also an account of tables relating to life assurance and annuities, astronomical tables, commercial tables, &c.

Reference should also be made to R. Mehmke's valuable article "Numerisches Rechnen" in vol. i. pt. ii. pp. 941–1079 of the *Encyk. der math. Wiss.* (Leipzig, 1900–4), which besides tables includes calculating machines, graphical methods, &c. (J. W. L. G.)

TABLE MOUNTAIN (Dutch *Tafelberg*), a name frequently given in South Africa to flat-topped hills and mountains, there a characteristic feature of the scenery. Occasionally such hills are called *plat, i.e.* flat, *bergen*. Specifically Table Mountain is the mountain which arises behind Table Bay, in the Cape Peninsula, Cape Town lying at its seaward base and on its adjacent lower slopes. The mountain forms the northern end of a range of hills which terminates southward in the Cape of Good Hope. The northern face of the mountain, overlooking Table Bay, extends like a great wall some two miles in length, and rises precipitously to a height of over 3500 ft. The face is scored with ravines, a particularly deep cleft, known as The Gorge, affording the shortest means of access to the summit. East and west of the mountain and a little in advance of it are lesser hills, the Devil's Peak (3300 ft.) being to the east and Lion's Head (2100 ft.) to the west. Lion's Head ends seaward in Signal Hill (1100 ft.). The western side of Table Mountain faces the Atlantic, and is flanked by the hills known as The Twelve Apostles; to the south Hout's Bay Nek connects it with the remainder of the range; on the east the mountain overlooks the Cape Flats. On this side its slopes are less steep, and at its foot are Rondebosch, Newlands, Wynberg, and other residential suburbs of Cape Town. The ascent of the mountain from Wynberg by Hout's Bay Nek is practicable for horses. The surface of the summit (the highest point is variously stated at 3549, 3582 and 3850 ft.) is broken into small valleys and hills, and is covered with luxuriant vegetation, its flora including the superb orchid *Disa grandiflora* and the well-known silver tree. The Kasteel-Berg (Castle Mount), a northern buttress of the mountain, has its own peculiar flora. Table Mountain and its connected hills are famous for the magnificence of their scenery. The kloof between the mountain and Lion's Head is of singular beauty. The view from the summit overlooking Table Bay is also one of much grandeur.

The south-east winds which sweep over Table Mountain frequently cause the phenomenon known as "The Table-cloth." The summit of the mountain is then covered by a whitish-grey cloud, which is being constantly forced down the northern face towards Cape Town, but never reaches the lower slopes. The clouds (not always caused by the south-easter) form very suddenly, and the weather on the mountain is exceedingly changeable. The rainfall on the summit is heavy, 72·14 inches a year being the average of twelve years' observations. This compares with an average of 54·63 inches at Bishop's Court, Newlands, at the foot of the mountain on the east and with 25·43 inches at Cape Town at the northern foot of the mountain. The relative luxuriance of the vegetation on the upper part of the mountain, compared with that of its lower slopes, is due not only to the rainfall, but to the large additional moisture condensed from clouds. The result of experiments conducted by Dr Marloth (*Trans. S. Afrn. Phil. Soc.* for 1903 and 1905) goes to show that during cloudy weather the summit of the mountain resembles an immense sponge, and that this condensation of moisture considerably influences the yield of the springs in the lower part of the mountain.

TABLE-TURNING. When the movement of modern spiritualism first reached Europe from America in the winter of 1852–3, the most popular method of consulting the "spirits" was for several persons to sit round a table, with their hands resting on it, and wait for the table to move. If the experiment was successful the table would rotate with considerable rapidity, and would occasionally rise in the air, or perform other movements. Whilst by many the movements were ascribed to the agency of spirits, two investigators—count de Gasparin and Professor Thury of Geneva—conducted a careful series of experiments by which they claimed to have demonstrated that the movements of the table were due to a physical force emanating from the bodies of the sitters, for which they proposed the name "ectenic force." Their conclusion rested on the supposed elimination of all known physical causes for the movements; but it is doubtful from the description of the experiments whether the precautions taken were sufficient to exclude unconscious muscular action or even deliberate fraud.

In England table-turning became a fashionable diversion and was practised all over the country in the year 1853. Dr John Elliotson and his followers attributed the phenomena to mesmerism. The general public were content to find the explanation of the movements in spirits, animal magnetism, odic force, galvanism, electricity, or even the rotation of the earth. James Braid, W. B. Carpenter and others pointed out, however, that the phenomena obviously depended upon the expectation of the sitters, and could be stopped altogether by appropriate suggestion. And Faraday devised some simple apparatus which conclusively demonstrated that the movements were due to unconscious muscular action. The apparatus consisted of two small boards, with glass rollers between them, the whole fastened together by indiarubber bands in such a manner that the upper board could slide under lateral pressure to a limited extent over the lower one. The occurrence of such lateral movement was at once indicated by means of an upright haystalk fastened to the apparatus. When by this means it was made clear to the experimenters that it was the fingers which moved the table, not the table the fingers, the phenomena generally ceased. The movements were in fact simply an illustration of automatism. But Faraday's demonstration did little to stop the popular craze.

By believers the table was made to serve as a means of communicating with the spirits; the alphabet would be slowly called over and the table would tilt at the appropriate letter, thus spelling out words and sentences. Some Evangelical clergymen discovered by this means that the spirits who caused the movements were of a diabolic nature, and some amazing accounts were published in 1853 and 1854 of the revelations obtained from the talking tables.

Table-turning is still in vogue amongst spiritualist circles. The device was employed with success by Professor Charles Richet and others in thought-transference experiments.

See A. E. de Gasparin, *Des Tables tournantes, du Surnaturel*, &c. (Paris, 1854); Thury, *Des Tables tournantes* (Geneva, 1855); Faraday's letter on Table-turning in *The Times*, 30th June 1853. *Quarterly Review*, Sept. 1853—article by Carpenter on Spiritualism, &c.; Mrs De Morgan, *From Matter to Spirit* (London, 1863); Ch. Richet, *Proceedings S.P.R.*, vol. v. F. Podmore, *Modern Spiritualism* (London, 1902), ii. 7-21, gives an account of the movement in 1853, with references to contemporary pamphlets and newspaper articles. (F. P.)

TABLINUM (or *tabulinum*, from *tabula*, board, picture), in Roman architecture, the name given to an apartment generally situated on one side of the atrium and opposite to the entrance; it opened in the rear on to the peristyle, with either a large window or only an anteroom or curtain. The walls were richly decorated with fresco pictures, and busts of the family were arranged on pedestals on the two sides of the room.

TABOO (also written *tapu* and *tabu*), the Polynesian name given to prohibitions enforced by religious or magical sanctions. As a verb it means to "prohibit," as an adjective "prohibited, sacred, dangerous, unclean."

1. The word "taboo" or its dialectical forms are found throughout Polynesia; in Melanesia the term is *tambu;* in various parts of Malaysia and the East Indies *pantang*, *bobosso*, *pamalli*, &c.; in Madagascar *fadi* includes taboo; in North America the Dakota term *wakan* bears a similar meaning. Taboo is perhaps derived from *ta*, to mark, and *pu*, an adverb of intensity.

2. *Fundamental Ideas.*—In *taboo* proper are combined two notions which with the progress of civilization have become differentiated—(i) sacred and (ii.) impure, or unclean; it must be borne in mind that the impurity is sacred, and is not derived from contact with common things. It does not imply any moral quality; it has been defined as an indication of "a connexion with the gods, or a separation from ordinary purposes and exclusive appropriation to persons or things considered sacred; sometimes it means devoted by a vow." This definition does not cover the whole connotation of taboo as it is employed at the present day, but it indicates clearly the non-moral character of the idea. The ordinary usage is perhaps best defined—the statement that taboo is "negative magic," *i.e.* abstinence from certain acts, in order that undesired magical results may not follow; in this sense a taboo is simply a ritual prohibition. Properly speaking taboo includes only (*a*) the sacred (or unclean) character of persons or things, (*b*) the kind of prohibition which results from this character, and (*c*) the sanctity (or uncleanness) which results from a violation of the prohibition. The converse of taboo in Polynesia is *noa* and allied forms, which mean "*general*" or "common"; by a curious coincidence *noa* is the term used in Central Australia to express the relation of persons of opposite sexes on whose intercourse there is no restriction.

3. *Classification.*—Various classes of taboo in the wider sense may be distinguished: (i) natural or direct, the result of *mana* (mysterious power) inherent in a person or thing; (ii.) communicated or indirect, equally the result of *mana*, but (*a*) acquired or (*b*) imposed by a priest, chief or other person; (iii.) intermediate, where both factors are present, as in the appropriation of a wife to her husband. These three classes are those of taboo proper. The term taboo is also applied to ritual prohibitions of a different nature; but its use in these senses is better avoided. It might be argued that the term should be extended to embrace cases in which the sanction of the prohibition is the creation of a god or spirit, *i.e.* to religious interdictions as distinguished from magical, but there is neither automatic action nor contagion in such a case, and a better term for it is Religious interdiction.

4. *Objects.*—The objects of taboo are many: (i.) direct taboos aim at (*a*) the protection of important persons—chiefs, priests, &c.—and things against harm; (*b*) the safeguarding

of the weak—women, children and common people generally—from the powerful *mana* (magical influence) of chiefs and priests; (*c*) the provision against the dangers incurred by handling or coming in contact with corpses, by eating certain foods, &c.; (*d*) the guarding the chief acts of life—birth, initiation, marriage and sexual functions, &c., against interference; (*e*) the securing of human beings against the wrath or power of gods and spirits; (*f*) the securing of unborn infants and young children, who stand in a specially sympathetic relation with one or both parents, from the consequences of certain actions, and more especially from the communication of qualities supposed to be derived from certain foods. (ii.) Taboos are imposed in order to secure against thieves the property of an individual, his fields, tools, &c.

5. *Sanctions.*—The sanctions of taboo may be (i.) natural or direct; (ii.) social or indirect. Natural sanctions are (*a*) automatic. where the punishment of the offender results from the operation of natural laws without any element of volition, just as some kinds of magic are held to bring about their results without the intervention of a spirit; (*b*) animistic, where the penalty results from the wrath of a god, deceased human being, or other spirit. The motive of the social sanction is ultimately religious or magical, but the penalties incurred by the violator of a taboo are social; they are inflicted by other members of the community, firstly, as a means of averting the supernatural sanctions, which, not having fallen on the actual offender, may visit his innocent fellows; and secondly, as a means of discouraging other offenders; in these cases the criminal is not himself taboo, but, thanks to his *mana*, braves the supernatural consequences; the social penalty is also inflicted on those who, like mourners, are themselves taboo and refuse to take steps to seclude themselves, in defence of the community; in the first class the social penalty is at once repressive and prophylactic, saving the innocent by punishing the guilty, and thus averting by a piaculum the vengeance which would otherwise fall somewhere; in the second the penalty is purely repressive.

The violation of a taboo makes the offender himself taboo; other penalties are not unkown: thus a man who partakes of a forbidden animal will break out in sores or the animal will reproduce itself within him and devour his vitals. Sometimes it is thought that the penalty falls on the kinswomen of the offender and that they produce, instead of children, animals of the taboo species. In Melanesia burial-grounds are taboo, and if the shadow of a passer-by falls on one, this entails upon him the loss of his soul; sometimes misfortune is held to dog the footsteps of the offender in this life and the next. But in some of these cases the observer who reports them has probably confused taboos proper with negative magic. The social sanctions range from the death penalty down to the infliction of a fine or exaction of money compensation; the Polynesian custom of despoiling a man who breaks a taboo is perhaps a special case of this penalty, but the practice of ceremonial plundering cannot always be so explained, and may perhaps in this case too be capable of an entirely different explanation.

Possibly the savage is more susceptible to suggestion than civilized man; at any rate, cases are not unknown in which the violation of a taboo has been followed by illness or even death, when the offender discovers his error. Not unnaturally rites of purification act as counter suggestions and save the offender from the effects of his erroneous beliefs.

6. *Mana.*—In the case of automatic taboos, and to some extent of other ritual prohibitions, the penalties for violation are unequal; they may be regarded as varying with the relation between the *mana* of the person or object and the *mana* of the offender against the prohibition. In the words of Dr R. H. Codrington, *mana* "is a power or influence, not physical and in a way supernatural; but it shows itself in physical force or in any kind of power or excellence which a man possesses. This *mana* is not fixed in anything, and can be conveyed in almost anything; but spirits, whether disembodied souls or supernatural (*i.e.* non-human) beings, have it and can impart it; and it essentially belongs to personal beings to originate it, though it may act through the medium of water, or a stone or a bone" (cf. the *suhman* of West Africa, in Fetishism). Persons or things which are regarded as taboo may be compared to objects charged with electricity; they are the seat of a tremendous power which is transmissible by contact, and may be liberated with destructive effect if the organisms which provoke its discharge are too weak to resist it; the result of a violation of a taboo depends partly on the strength of the magical influence inherent in the taboo object or person, partly on the strength of the opposing *mana* of the violator of the taboo. Thus, kings and chiefs are possessed of great power, and it is death for their subjects to address them directly; but a minister or other person of greater *mana* than common can approach them unharmed, and can in turn be approached by their inferiors without risk. The burial-place is often taboo for the common people, save when they are actually engaged in funeral rites; but the sorcerer, thanks to his indwelling power, can resist the deadly influences which would destroy the common folk, and may enter a cemetery for ritual or other purposes. So too indirect taboos depend for their strength on the *mana* of him who imposes them; if it is a chief or a priest, they are more powerful than those imposed by a common person. The *mana* of the priest, or chief, does not depend on his position; on the contrary, it is thanks to his *mana* that he has risen above the common herd.

7. *Transmissibility.*—It is characteristic of taboo proper that it is transmissible; as a logical corollary of this idea, acquired taboo may be thrown off by suitable magical or purificatory ceremonies; the mourner, or he who takes part in funeral ceremonies; was perhaps at the outset regarded as a person charged with death-dealing power, and fear of the spirit of the dead may well have been secondary; however this may be, we can distinguish taboos, the violation of which charges with supernatural power the human being who violates them, thus rendering him directly dangerous to the community, from ritual prohibitions the violation of which makes him an outcast, not as himself dangerous, but as a person obnoxious to the gods. The ritual prohibitions of pregnancy, and the restrictions imposed on the parents during the early childhood of their offspring, are not taboos proper; though they are transmissible, they do not depend on the transmission of an undifferentiated *mana*; what the parents seek to avoid is often the transmission of specific qualities, conceived as inherent in certain animals, *e.g.* cowardice in the hare, slowness in the tortoise; the animal is not necessarily in any sense sacred, nor are the parents, if they disregard the prohibition, liable to any penalty, direct or indirect; neither they nor the child are rendered taboo by any violation; finally, save that the child acquires its qualities by a sympathetic process, the abstinence of the parents is correlative to the converse operation of eating an animal or otherwise acquiring by a magical process the good qualities inherent in anything.

8. *Duration of Taboos, Imposition, and Abrogation.*—Taboo is properly sanctity and the kind of interdict which it entrains; by a transference of meaning it is sometimes used of a period of time during which ritual prohibitions of a religious nature are enforced; these periods were proclaimed in Polynesia on important occasions and sometimes lasted for many years; they may be termed interdicts. Many persons and things are permanently taboo; among them may be mentioned kings and chiefs, the property of dead persons and, a fortiori, their bodies or anything in contact with them. Other taboos are temporary. Temporary direct taboos, whether natural or acquired, may be removed by a process of desacralization or of purification. Thus, new crops are frequently taboo till the chief has partaken of them; his *mana* enables him to run risks which would be fatal to ordinary people, and the crops thus desacralized become free to all; perhaps, however, we may regard the practice as a case of sacralization, in which the chief, like a sacrificing priest, acquires special sanctity, and in so doing fortifies his people by a sympathetic process against supernatural dangers. A

new-born child may also make the crops *noa*, just as it may remove the taboo from a temporarily affected person.

In the Tonga Islands a person who became taboo by touching a chief or his property had to put away his sacred character, before he was allowed to make use of his lands, by touching the soles of a higher chief's feet and washing in water. Strangers before penetrating into a village, priests after a sacrifice, warriors, women after child-birth, at puberty, the menstrual period, &c., must submit to lustration. Sometimes the purification was effected by inhaling the sacred contagion; in New Zealand a chief who touched his own head had to apply his fingers to his nose and snuff up the sanctity abstracted from his head. In other cases mere lapse of time suffices to cause the removal of a taboo; in Melanesia, where taboos are largely animistic, mourners go away for some months and on their return are free from taboo, the explanation given being that the spirit has got tired of waiting for them.

Indirect taboos are imposed in various ways, and unless they are removed may be as permanent as direct taboos, save that the death of the persons by whom they are imposed must result in their abrogation. In Polynesia a general taboo was imposed by proclamation; a chief might also taboo particular objects to his own use by naming them after a part of his person; more permanent was the taboo imposed by touching an object, but this too could be removed by proper ceremonies. In Melanesia, corresponding to the animistic character of *tambu*, a method of imposing taboo is to mention the name of some spirit.

Taboo objects were marked in various ways: a piece of white cloth, a bunch of leaves, a bundle of branches (in Melanesia) painted red and white, a stick with dry leaves, are among the methods in common use; in Samoa one mark of a taboo was to set up the image of a shark; in New Zealand it sufficed to give a chop with an axe to make a tree taboo. Particular taboos thus imposed seem to be abrogated by the declaration of the person who imposes them; on the other hand, he, no less than others, is bound by the taboo until it is abrogated.

9. *Taboo and the Evolution of Punishment.*—Penal codes may be largely, if not wholly, traced to religious sources of which taboo is certainly one; the violation of any taboo may imperil the life or health of other members of the community besides the offender; it calls for measures intended to discourage others, as well as for steps to avert the immediate evil; if a taboo imposed by a chief is disregarded, not only has his authority been set at nought, but he, and in the second place, other members of the community may suffer if the real offender gets off scot free, thanks to the *mana* which enables him to defy supernatural sanctions. The importance of this in the evolution of law and order is manifest; for whereas a chief would not intervene to protect the property of an individual simply to punish what we regard as a transgression, he is bound to do so when a taboo is broken. That the taboo may be of his own imposition does not affect the question, for he is bound to observe it himself, and conversely may suffer supernatural penalties when it is violated by another. Just as blood-guiltiness may be wiped out by composition, the violation of a taboo may be atoned for by a money payment or similar consideration for the revocation of the taboo; this compensation seems to have a retrospective effect, and thereby removes the dangers brought into existence by the violation.

10. *Taboo and Moral Obligation.*—In proportion as a taboo becomes a custom and its sanctions fall into the background and are forgotten, its obligations thus transformed are one source of the categorical imperative, the distinguishing feature of which is that it is non-rational and instinctive. We are ignorant of the origin of exogamy and the prohibition of incest, the sanctions of which in Australia and among other peoples of low culture seem to be purely social, for as a rule irregular marriages seem to be regarded simply as offences against tribal morality; if the rules were originally of the nature of taboos, the transformation into customs must have been very early, and the same may be said of the rules by which the relations of members of the same kin are regulated.

11. *Royal and Priestly Taboos.*—Among people of low culture the chief, and in higher cultures the king, is sometimes held responsible for the order of nature, the increase of the crops, and the welfare of his people generally; it is therefore of the highest importance that nothing should diminish or perturb his influence, and, as a logical consequence, the life of the king, and to a less degree of the chief, is surrounded with a complicated system of taboos and ritual prohibitions. Even where this idea of the magician-king or chief is not found, his position is an expression of the more powerful *mana* dwelling within him; consequently the king or chief may not come in contact with the common folk, for fear his touch should blast them, as lightning withers the life of the oak. We can usually see why a king or chief must hold aloof from those whom he might injure, but it is not always easy to see the basic idea of the taboos, if such they be, which aim at protecting the potentate, or ensuring his due regulation of the course of nature. Some African kings may not see the sea; another may not lie down to sleep; in the Mentawei Islands the chief will die who during an interdict eats at the same time as common people; it is frequently forbidden to see the king partake of food. At a further stage of evolution these taboos degenerate into mere rules of etiquette, the violation of which involves the punishment of the offender, but the punishment is justified on formal grounds only. In early society the king and the priest often stand very near together; just as we find a war chief and a peace chief, so we meet with political and religious sovereigns. Sometimes the political king is also the priest and therefore sacred; the web of ritual prohibition woven round him may result in the creation of a secular authority like the Tycoon in Japan, who can rule the state without reference to the ceremonial observances prescribed for the nominal sovereign. Sometimes, on the other hand, the priest bears the title of king, but has lost even the shadow of political power and is free to perform his priestly functions. In these, however, as we see by the example of the flamen dialis at Rome, or the kings of fire and water in Cambodia, he is still hedged round by manifold restrictions as a person who must be protected from doing harm to others or suffering harm himself. In the exercise of his priestly functions he is called upon to offer sacrifice; before fulfilling his office he is often required to submit to additional ritual prohibitions; his personal sanctity, already great, is augmented, and his approach to the sanctuary facilitated. Conversely, the sacrifice over, he performs lustral rites, in part to free himself from the taint of errors of ritual, but also to desacralize himself.

12. *Funerary and Allied Taboos.*—Taboos of mourners, widows, and of the dead are common all the world over, but they are especially prominent in Melanesia. These are explained on an animistic hypothesis as due to the fear of the dead man's spirit, but we seem to see traces, *e.g.* in Madagascar, of the idea that the contagion of death and not the wrath of the dead is the underlying motive; for it is not clear why the soul of a dead kinsman should necessarily be hostile. With funerary taboos may be compared taboos of warriors both on and after an expedition, taboos of hunters during the chase and especially after killing a dangerous animal, taboos of cannibals, and on participants in all other ceremonies which involve contact with death or the dead. Temporary seclusion and lustration before return to ordinary life are commonly prescribed for all in this category, even though their connexion with the dead be no closer than is implied in consanguinity. The property of the dead man is commonly burnt or deposited with him in the grave, in part as a protective measure, in part under the influence of belief in the continuity of this and the future life, and the need of supplying him with necessaries. Burial grounds are avoided, animals or plants from the neighbourhood are not used as food. Finally the name of the dead is not used, partly for fear of summoning him by the power of the word, but partly also from a conviction that, like the name of a king or chief, it is too holy or too dangerous for common use.

13. *Taboos of the Sick.*—Both disease and death are unnatural in the eyes of the savage; they are often the result of the magic

of some enemy; but they may also be the result of an infraction of a taboo. Some part of the funerary taboos may perhaps be referred to this belief; whatever be the case with taboos of the dead, there can be no question that the sick are secluded or even abandoned, subjected to rites of purification and to restrictions of various sorts, not because their malady is contagious in our sense, but because they are temporarily taboo and dangerous to the health of the community. The sick have imposed on them curative as well as prophylactic taboos; in Madagascar the sun is said to "die" when it sets; therefore it is forbidden to a sick man to look upon it as it goes down.

14. *Taboos of Women, Sexual Taboos, Avoidance.*—The age of puberty is especially dangerous for both sexes; in the case of a woman the danger is not so much for herself as for others, and results from her physiological state; this danger is renewed with each successive menstrual period, and the frequently long seclusion at puberty finds a parallel in the universal practice in lower stages of culture of separating adult females, not only from males, but from the whole of the community at such periods. At puberty girls are confined for months or even years; they may not see the sun nor touch the earth; many foods are forbidden them, and special costumes are prescribed for them, as for mourners. The expectant mother is taboo for months before the birth of her child, and her disabilities are not removed for a long period after delivery. Women may not look upon the performance of rites of initiation nor of secret societies; they may not eat new crops in New Caledonia till long after the men have partaken of them; they may often not approach the men's club-house. Both parents, but especially the mother, are subjected to restrictions, having for their object the preservation of the health of the unborn or newly born child. Women are often forbidden to eat with their husbands; nor may they share his labours, especially at sea.

The relations of the sexes are regulated by complicated rules, but they are not necessarily taboos. In the first place, laws of exogamy and similar regulations limit the field of choice; even where no obstacle on this side is present the intercourse of the sexes is often, especially at first, hedged round with numberless interdictions and rites. Connected with the rules of exogamy are the customs of avoidance, which prescribe that a man may not speak to nor even look at his mother-in-law, sometimes also his father-in-law, daughter, and other relatives; in like manner the wife must avoid the husband's relatives, and the brother may often not speak to the sister.

15. *Other Taboos.*—Taboos of various kinds are imposed on strangers, on sorcerers, and on children. Certain places are taboo; taboos protect the crops and ensure that landmarks are not removed. In fact the number of taboos is so great that it is impossible to mention them in detail.

16. *Distribution.*—Although taboo is a Polynesian word the institution is far from being restricted to Oceania. Similar prohibitions, though they seldom reached the Polynesian level, are found in America, Africa, and especially Madagascar, North and Central Asia, and among the non-Aryan tribes of India. But taboo and its survivals are not confined to the uncivilized.

17. *Developments of Taboo.*—It would be remarkable if a feature which has taken such deep root in the custom and belief of savage and barbarous peoples did not leave a marked impress on the faiths of higher cultures. Just as the gods have become moral *pari passu* with mankind, so the ceremonially clean has become the physically and morally clean, the pure has become the moral, and taboo has changed its name to holiness. At a certain point in evolution the notion of unclean, sometimes positive and implying the possession of dangerous properties, sometimes negative and connoting no more than mere absence of holiness, which is in this case indistinguishable from *mana*, becomes a prominent element in religion. At a later stage and as a result of the greater weight attached to morality, the positive uncleanness falls into the background, leaving only the negatively unclean, the unholy, which is not in itself death-dealing, but may, like its savage analogue, call down on the community, innocent and guilty alike, the wrath of higher powers, the remedy being, not so much the punishment of the offender, still less mere physical purification, but their moralized analogues, prayer, fasting and repentance.

18. *Among the Greeks.*—The general word for taboo among the Greeks in ἄγος, which may bear the sense of "sacredness" or "pollution"; derivatives occur in the same meanings. Usually, however, the notions of sacred and unclean are distinguished by the use of different terms from this root, ἁγνός for sacred, ἐναγής for unclean or accursed. The rules of the Greek ἁγνεία (season of taboo) do not differ markedly from those of the Polynesian. Corresponding to the war-taboo of Oceania we find in Homer that the army (*Od.* xxiv. 81) and the sentinel (*Il.* x. 56, xxiv. 681) are sacred; and we learn from Plato that warriors never eat fish, from which indeed there was a general custom of abstinence except under the pressure of famine. The epithets ἱερός, δῖος, &c., which may point to beliefs similar to those of Polynesia, are applied to chiefs and kings, and further to the swineherd, thus suggesting that the pig, which bore a mixed reputation for holiness and uncleanness (ceremonial) both in Egypt and west Asia, was similarly regarded in Greece.

19. *Among the Romans.*—The term for taboo is *sacer;* any one who removed a landmark became *sacer* and was outlawed, any citizen having the right to kill him. *Consecratio capitis et bonorum* was the term for devotion to the nether gods. The flamen dialis and his wife were hedged in by a perfect network of ritual prohibitions; he might not ride upon nor even touch a horse; his eyes might not fall on an army under arms; he might not walk under a vine; he might not name a goat, raw meat, beans, ivy, a dog, and so on; his hair might be cut only by a freeman; he might not touch a corpse. The flaminica might not comb her hair at certain festivals; she was taboo (feriata) after hearing thunder till she had purified herself by a sacrifice. The Roman *feriae* were periods of taboo.

20. *Among the Jews.*—The Hebrew for holy is קדש which means "separated, cut off," while its correlative חל means "open for common use"; another sense of *sacer* is conveyed by חרם "accursed, devoted to destruction." Holiness is transmissible by contact (Ezek. xliv. 19, xlvi. 20; Ex. xxix. 37; Lev. vi. 27). It is distinct from purity in the moral sense; the names of the hieroduli קדשים and hierodula קדשה are connected with the word קדש. Taboo among the Jews are: (1) things connected with Jehovah, his name is holy and terrible; his arm is holy; holy places are taboo (see SANCTUARY); the ark is actively dangerous, and Uzzah, no less than the men of Bethshemesh, pays the penalty for too nearly approaching it; (2) the Nazarite might not partake of certain foods, nor touch a dead body nor shave his head, which was specially sacred; (3) in fact any one who touched a dead body was unclean and could communicate his uncleanness to others; (4) the birth of a child made the mother taboo; she was required to purify herself; (5) leprosy, menstruation, and sexual functions generally occasioned longer or shorter periods of uncleanness; and warriors, who were taboo on a campaign, were required to observe continence; (6) certain foods were taboo, and the uncleanness might be communicated to an earthen vessel, which, under certain circumstances, would be broken, like a pot in Polynesia; (7) the use of iron was forbidden in the construction of the temple; (8) a field sown with different kinds of herbs "becomes holy"; and (9) bystanders are warned not to approach a heathen rite, lest they be "sanctified"; (10) to the Polynesian interdicts, often termed taboos, corresponded certain periods of time, such as the Sabbath and the Jubilee year, but these are not connected with taboo proper.

TABOR, a town in western Bohemia, on the Francis-Joseph railway, 104 kilometres from Prague. Pop. (1908) 10,703. It is the chief town of a government district and the seat of a provincial law-court, and also of an industrial school. The town was founded in 1420 by the more advanced party of the church-reformers or Hussites, who, as it became their centre, soon began to be known as the Taborites. The town is situated on the summit of an isolated hill separated from the surrounding country by the Luznice stream and by an extensive pond, to which the Hussites gave the biblical name of Jordan. The historical importance of the city of Tabor only ceased when it was captured by King George of Poděbrad in 1452. Though a large part of the ancient fortifications has recently been demolished, Tabor—or Hradiste Hory Tabor, the castle of the Tabor Hill, as it was called in the Hussite period—has still preserved many memorials of its past fame. In the centre of the city is the market-place (*rynk*). Only very narrow streets lead to it, to render the approach to it more difficult in time of war. In the centre of the market-place is the statue of Žižka, the greatest of the Taborite leaders. Here also is the diaconal church, built in 1516 in the style of the Bohemian Renaissance, and the town hall, in connexion with which a museum has been founded, which contains interesting memorials of the Hussite period. Some parts of the ancient fortifications and the very ancient Kotnov tower also still exist.

See Thir, *Hradiste Hory Tabor* (1895).

TABRIZ, the capital of the province of Azerbaijan in Persia, situated in the valley of the Aji Chai, "Bitter River," at an elevation of 4400 ft. in 38° 4′ N., 46° 18′ E. Based on a census taken in 1871 the population of Tabriz was in 1881 estimated at 165,000, and is now said to be about 200,000.

The popular etymology of the name Tabriz from *tab*=fever, *rīz*=pourer away (verb, *rīkhtan*=pour away, flow; German *rieseln?*), hence "fever-destroying," is erroneous and was invented in modern times. It is related that Zobeideh, the wife of Harun-al-Rashid, founded the town in 791 after recovering there from fever, but the earlier chronicles give no support to this statement, and it is nowhere recorded that Zobeideh ever visited Azerbaijan, and the name Tabriz was known many centuries before her time. In 1842 Hammer-Purgstall correctly explained the name as meaning the "warm-flowing" (*tab*= warm, same root as *tep* in "tepid") from some warm mineral springs in the neighbourhood, and compared it with the synonymous Teplitz in Bohemia. In old Armenian histories the name is Tavresh, which means the same. The popular pronunciation *to* and *tau* for *tab* has given rise to the spellings Toris and Tauris met with in older travellers and used even now.

Overlooking the valley on the N.E. and N. are bold bare rocks, while to the S. rises the majestic cone of Sahand (12,000 ft.). The town possesses few buildings of note, and of the extensive ruins few merit attention. The ark, or citadel, in the south-west extremity of the city, now used as an arsenal, is a noble building of burnt brick with mighty walls and a tower 120 ft. in height. Among the ruins of old Tabriz the sepulchre of the Mongol king, Ghazan Khan (1295–1304), in a quarter once known as Shanb (generally pronounced Sham and Shām) i Ghazan, is no longer to be distinguished except as part of a huge tumulus. The great shanb (cupola or dome) and other buildings erected by Ghazan have also disappeared. They stood about 2 m. S.W. from the modern town, but far within the original boundaries. The "spacious arches of stone and other vestiges of departed majesty," with which Ker Porter found it surrounded in 1818, were possibly remains of the college (*medresseh*) and monastery (*zavīeh*) where Ibn Batūta found shelter during his visit to the locality. On the eastern side of the city stand the ruins of the Masjed i Jehan Shah, commonly known as the Masjed i Kebud, or "Blue Mosque," from the blue glazed tiles which cover its walls. It was built by Jehan Shah of the Kara Kuyunli, or Black Sheep dynasty (1437–1467).[1] Tabriz is celebrated as one of the most healthy cities in Persia.

Tabriz was for a long period the emporium for the trade of Persia on the west, but since the opening of the railway through the Caucasus and greater facilities for transport on the Caspian, much of its trade with Russia has been diverted to Astara and Resht, while the insecurity on the Tabriz-Trebizond route since 1878 has diverted much commerce to the Bagdad road. According to consular reports the value of the exports and imports which passed through the Tabriz custom-house during the years 1867–73 averaged £593,800 and £1,226,660 (total for the year, £1,820,460); the averages for the six years 1893–9 were £212,880 and £544,530. There are reasons to believe that these values were considerably understated. For the year 1898–9 the present writer obtained figures directly from the books kept by the custom-house official at Tabriz, and although, as this official informed him, some important items had not been entered at all, the value of the exports and imports shown in the books exceeded that of the consular reports by about 10 per cent. Since that time the customs of Azerbaijan have been taken over by the central customs department under Belgian officials, and it is stated that the trade has not decreased. British, Russian, French, Turkish and Austrian consulates and a few European commercial firms are established at Tabriz; there are also post and telegraph offices. Tabriz has suffered much from earthquakes, notably in 858, 1042 and 1721, each time with almost complete destruction of the city. (A. H.-S.)

TABULARIUM (*tabula*, board, picture, also archives, records), the architectural term given to the Record office in ancient Rome, which was built by Q. Lutatius Catulus, the conqueror of the Cimbri. It was situated on the west side of the Forum Romanum, and its great corridor, 220 ft. long, raised 50 ft. above the forum on a massive substructure, is still partly preserved. This corridor was lighted through a series of arches divided by semi-detached columns of the Doric order, the earliest example of this class of decoration, which in the Theatre of Marcellus, the Colosseum, and all the great amphitheatres throughout the Roman empire constituted the decorative treatment of the wall surface and gave scale to the structure. Traces of an upper corridor with semi-detached columns of the Ionic order have been found in the Tabularium, but this structure was much changed in the 13th century, when the Palace of the Senators was built.

TACHEOMETRY (from Gr. ταχύς, quick; μέτρον, a measure), a system of rapid surveying, by which the positions, both horizontal and vertical, of points on the earth's surface relatively to one another are determined without using a chain or tape or a separate levelling instrument. The ordinary methods of surveying with a theodolite, chain, and levelling instrument (see SURVEYING) are fairly satisfactory when the ground is pretty clear of obstructions and not very precipitous, but it becomes extremely cumbrous when the ground is much covered with bush, or broken up by ravines. Chain measurements are then both slow and liable to considerable error; the levelling, too, is carried on at great disadvantage in point of speed, though without serious loss of accuracy. These difficulties led to the introduction of tacheometry, in which, instead of the pole formerly employed to mark a point, a staff similar to a level staff is used. This is marked with heights from the foot, and is graduated according to the form of tacheometer in use. The azimuth angle is determined as formerly. The horizontal distance is

[1] This mosque is popularly attributed to Ghazan Khan (end of 13th century).

inferred either from the vertical angle included between two well-defined points on the staff and the known distance between them, or by readings of the staff indicated by two fixed wires in the diaphragm of the telescope. The difference of height is computed from the angle of depression or elevation of a fixed point on the staff and the horizontal distance already obtained. Thus all the measurements requisite to locate a point both vertically and horizontally with reference to the point where the tacheometer is centred are determined by an observer at the instrument without any assistance beyond that of a man to hold the staff.

Subtense method. The simplest system of tacheometry employs a theodolite without additions of any kind, and the horizontal and vertical distances are obtained from the angles of depression or elevation of two well-defined points on a staff at known heights from the foot, the staff being held vertically. In fig. 1 let T be the telescope of a theodolite centred over the point C, and let AB be the staff held truly vertical on the ground at A. Let P and P′ be the two well-defined marks on the face of the staff,

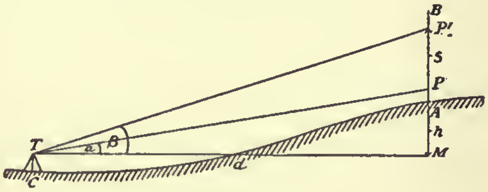

FIG. 1.

both of them at known heights above A, and enclosing a distance PP′ $=s$ between them. Let α and β be the measured angles of elevation of P and P′, and let d be the horizontal distance TM of the staff from the theodolite, and h the height PM of P above T. Then since

$$\mathrm{P'M}=d\tan\beta \text{ and } \mathrm{PM}=d\tan\alpha,$$

we have
$$s=\mathrm{P'M}-\mathrm{PM}=d(\tan\beta-\tan\alpha).$$

Therefore
$$d=\frac{s}{\tan\beta-\tan\alpha};\qquad h=\frac{s\tan\alpha}{\tan\beta-\tan\alpha}.$$

If TC, the height of the rotation axis of the telescope above the ground, $=q$, and if AP $=p$, then the height of A above C is $h-p+q$. If, as is usually the case, a number of points are determined from one station of the theodolite, and h_1, h_2, h_3, &c., be the values of h for the different points A_1, A_2, A_3, &c., then the difference of level of A_1 and A_2 will be h_2-h_1, that of A_1 and A_3 will be h_3-h_1, and so on. To ensure the essential condition that the staff is held vertical, it is usually provided with a small circular spirit-level, and the staff-holder must always keep the bubble in the centre of its run. No graduation of the staff is required beyond two well-defined black lines across the white face at P and P′, but the marks can be very usefully supplemented by wings fastened on the two sides of the staff, having their tops at right angles to the staff, at the same height as the points P and P′, and forming a continuation of the black lines. A convenient length for the staff is 12 ft., with the point P 2 ft. from the foot, and the point P′ at the top of the staff, so that $s=10$ ft.

With the above arrangement the staff can easily be read with a 5-inch theodolite at half a mile distance. But while it is frequently very useful to determine approximately points a long way off, the determinations will not be nearly so accurate as those of near points. Thus suppose that the distance of the staff is d, and the intercept on the staff is s, and suppose that the personal and instrumental error is $\delta\alpha$ (α being the angle subtended by s at the telescope); then since

$$d=\frac{s}{\tan\alpha},\frac{d(d)}{d\alpha}=-\frac{s}{\sin^2\alpha}=-s\frac{1+\tan^2\alpha}{\tan^2\alpha},\text{ or }\frac{d(d)}{d\alpha}=-s\frac{1+s^2/d^2}{s^2/d^2}=-\frac{1}{s}(s^2+d^2).$$

Therefore δd, the distance error, is given by the equation $\delta d=-\delta\alpha(s^2+d^2)/s$. But at distances of 5 chains or more s^2 will be very small compared with d^2 and may be neglected, so that $\delta d=-\delta\alpha.d^2/s$. Since $\delta\alpha$ may be considered as constant for all distances where the staff can be distinctly read, the distance error increases as the square of the distance. With small theodolites, where special care has not been given to the graduating and reading of the vertical circle, $\delta\alpha$ will probably amount to about 20″. At a quarter of a mile excellent work can be done. In carrying on a traverse line by this method with stations 10 or 12 chains apart, the theodolite being set up at points about midway between the stations, the probable distance error in a mile is about $3\frac{1}{2}$ ft., and the probable level error about 4 in. In 25 miles these probable errors would correspond to about 18 ft. and 20 in. respectively. This system of tacheometry is well adapted for distant readings, and from the great simplicity of the observations there is little likelihood of errors in the field. But the reduction work is rather heavier than is the case with some of the tacheometers described below. Since the accuracy of the method depends entirely upon the accuracy with which the vertical angles are measured, it is advisable that the vertical circle should be as large as possible, very finely and accurately divided, and fitted with good verniers and microscopes.

In Eckhold's omnimeter the vertical circle of the theodolite is dispensed with, and a saving of reduction work is effected by reading, not the vertical angles themselves, but the tangents of the angles.

In the Ziegler-Hager tacheograph the tangents are read not horizontally but vertically, and the arrangement is as follows:—In fig. 2 O is the axis of rotation of the telescope; mn is the axial line of a steel bolt, which carries on its top a knife-edge, on which the telescope rests by means of an agate plate. The bolt is carried by a slide in which it can be raised or lowered by a micrometer screw fitted with a graduated head. The slide plays between the vertical cheeks of a standard rigidly attached to the frame of the instrument, and it can be raised or lowered by a rack and pinion. The telescope, which rests on the knife-edge, follows the movement of the bolt. The slide carries on one side a vernier by which to read the divisions on a scale fixed to one of the vertical legs of the standard, and the zero point o of the scale is the point where the horizontal plane through O cuts the scale when the plane-table or upper plate of the theodolite is truly level. The scale is graduated in divisions, each of which is the $\frac{1}{100}$th part of the distance Oo, or h. The head of the micrometer screw which raises or lowers the steel bolt in the slide is graduated with a zero mark and with marks corresponding to a vertical movement of the knife-edge of $\frac{1}{100}h$, $\frac{1}{50}h$, &c. The instrument is used as follows:—Let AB be the surface of the ground, and BC a staff held vertically at B, and let CB be produced to meet the horizontal line through O in M. Let the head of the micrometer screw be turned till the zero division is exactly under the pointer. Let p be the zero division on the staff, and let the slide and bolt be raised by the rack and pinion movement till the axis of the telescope is directed towards p. Let v be the point where the line Op cuts mn, and let the tangent reading ov be taken on the scale. Then let the telescope be lowered by the micrometer screw in the slide till the division on the head of the screw marked 1 is exactly under the pointer; the knife-edge of the bolt has then been lowered through a distance vt equal to $h/100$. Let q be the point on the staff where the line Ot cuts it, and let the reading at q be taken. Then since the triangles between O and mn and O and CM are similar to each other, and vt is $\frac{1}{100}$th of Oo, therefore pq will be $\frac{1}{100}$th of OM, or OM $=100\times pq$. This gives the horizontal distance of the staff from O, and the vertical distance pM of p above O is OM tan MOp = OM × ov/Oo, and since ov has been read in

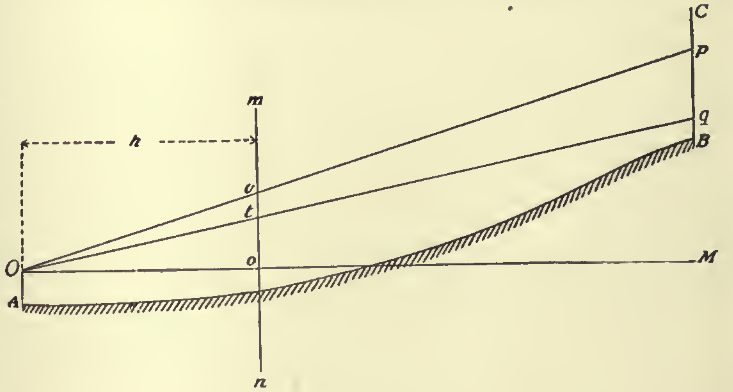

FIG. 2.

parts of which Oo contains 100, the distance pM is readily obtained. If the difference of elevation of B and A be required, the height pM must be reduced by pB and increased by OA, both known quantities. By this arrangement the reduction work of the observations is rendered extremely simple, and can readily be performed in the field. The instrument is well adapted for use with the plane-table.

Stadia method. Tacheometers in which the horizontal distance of the staff from the telescope is deduced from the readings of the staff indicated by two fixed wires in the diaphragm of the telescope will now be considered. In fig. 3 BC is a diaphragm fixed in a tube having fine horizontal wires at B and C. Let the end E of the tube be closed by a disk which has a minute hole at E, to which the eye can be applied. If P and D be the points on a vertical staff at which the lines EB and EC are observed to cut the staff, so that the intercept PD is known, then from similar triangles ED = (EC/BC)PD, and since EC and BC are constant, ED varies as PD. If, for instance, PD has a certain observed value when the staff is held at a certain distance ED, and has exactly half that value when the staff is held at another distance ED′, then the distance

ED′ is one-half of the distance ED, and so on in proportion. The distance ED can be instantly inferred from the readings of the staff, if the latter be suitably graduated. If, for example, it be desired to know the distance ED in yards, and by construction the proportion EC/BC = 50, then the intercept on the staff at 1 yard from E would be $\frac{1}{50}$th of a yard, or ·72 inch, the intercept at 2 yards from E would be 2×·72 inches, and so on. If therefore the staff be graduated with divisions of ·72 inch, and the intercept be 45 of such divisions, it would be inferred that the distance of the staff from E was 45 yards. The constant proportion EC/BC can be checked by measuring 100 yards from E and observing whether

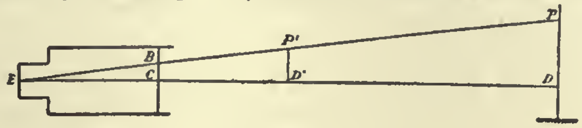

FIG. 3.

the intercept is exactly 100 divisions or not. If it is not, the wire diaphragm must be shifted in the tube until it is. In figs. 3, 4, 5 and 6 the distances are deduced from the readings of a central wire in the optical axis of the telescope and of a wire above it, for the sake of simplicity. The usual arrangement is to fit the diaphragm with a central wire and with one or two wires above and below it at equal distances from the central wire. The vertical angle of depression or elevation is fixed by directing the central wire to a well-defined division on the staff, and the distance of the staff is inferred from the readings given by the corresponding wires above and below the central wire.

The elementary form of tacheometer given above illustrates the general principle of the class of tacheometers now under consideration, and as leading up to the practical form, in which the staff is viewed with a telescope mounted in the manner of a theodolite. The simplest form is Reichenbach's tacheometer, which may be investigated as follows:—In fig. 4 let A be the object glass by which an image of the staff ST is formed at HK. The wire diaphragm is moved in the tube so as to coincide with the image,

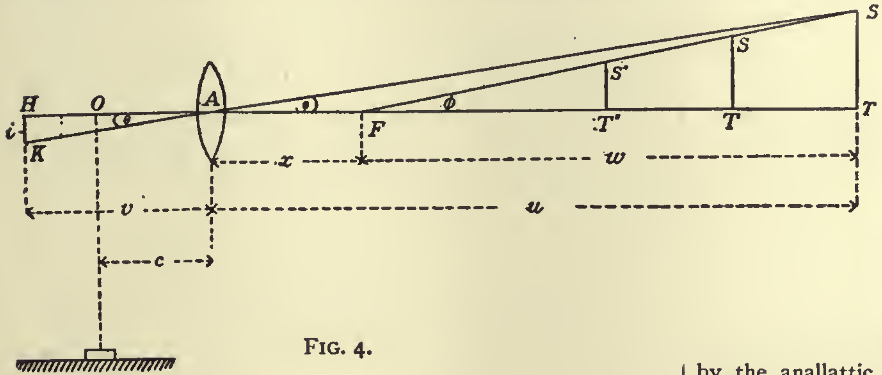

FIG. 4.

and the image and wires are viewed with an eye-piece (not shown) in the usual way. Let O be the point where the vertical axis of the instrument cuts the axis of the telescope, the instrument being centred over a peg, from which the distance to the staff is required. The object glass (of focal length $=f$) is at a distance c from O. Let AT $=u$ and AH $=v$, and the angle SAT = HAK $=\theta$. Then if i be the height of the image HK, $i=v\tan\theta$. Since $1/v+1/u=1/f$, we have $v=-uf/(u-f)$, and hence $i=uf\tan\theta/(u-f)$. Let F be some point on AT such that AF $=x$ and FT $=u'$. And let the angle SFT $=\phi$. Then $u=u'+x$ and $\tan\theta=u'\tan\phi/(u'+x)$, and therefore

$$i=\frac{(u'+x)f}{u'+x-f}\,\frac{u'}{u'+x}\cdot\tan\phi=\frac{fu'}{u'+x-f}\tan\phi;\text{ and, if } x=f,\ i=f\tan\phi.$$

If therefore the point F be taken at a distance f from the object glass, every intercept of the staff for positions between T and F, such as S′T′, S″T″, &c., which are bounded by the line FS, and for which consequently θ is the same, will have the same height of image at the diaphragm. Conversely, if K be a wire in the diaphragm it will cut the image of the staff for all positions of the staff between T and F in points that lie on the line FS. Now the intercept S″T″, half-way between F and T, will be one-half of ST, and therefore if the reading on the staff indicated by the wire in question be one-half of ST, it may be inferred that the position of the staff is half-way between F and T, and similarly for other distances. If the distance of ST from O is required, as is usually the case, a quantity $f+c$ must be added to every distance from F determined as above.

It is very seldom that the line of sight AT of the telescope is at right angles to the staff. In general it is more or less inclined to the staff, which is almost always held vertical, and the horizontal and vertical distances of the staff from the axis of rotation of the telescope are found thus:—In fig. 5 let ST be the observed intercept on the staff when the telescope is inclined at an angle α to the horizontal. Draw TS′ at right angles to OT. The angle TS′S will be very nearly a right angle, and STS′ may be taken as equal to α. If there were n graduations (each corresponding to 1 yard in distance) in ST, there would be $n\cos\alpha$ graduations in

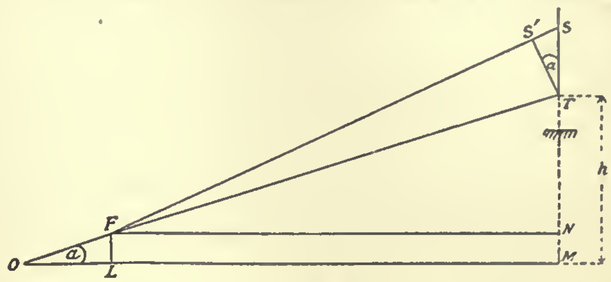

FIG. 5.

S′T, and therefore the distance of the staff from F, as inferred from the observed number of graduations in ST, must be multiplied by $\cos\alpha$ to give the true distance FT. Again FN = FT $\cos\alpha$, so that the distance inferred from the observed number of graduations in ST must be multiplied by $\cos^2\alpha$ to give the horizontal distance of F from T. To this must be added the distance OL = OF $\cos\alpha=(f+c)\cos\alpha$ to get the horizontal distance, OM, of O (the vertical axis of the instrument) from T. This value of OM must be multiplied by $\tan\alpha$ to obtain the value of h, the vertical distance of T from O. Tables of the value of $\cos\alpha$, $\cos^2\alpha$, and $\tan\alpha$ are necessary to facilitate these calculations.

In this tacheometer the distances as inferred from the readings of the staff are the distances of the staff from F and not from O. This defect was remedied by Porro, who added a lens (called the anallattic lens) to the telescope. The arrangement of the telescope as manufactured by Messrs Troughton and Simms, is as follows:—In fig. 6 O is the point where the vertical axis of the instrument cuts the axis of the telescope. The object glass is fixed at a distance c from O, and the anallattic lens at a distance d from the object glass. The distances c and d are chosen to suit the constructive conveniences of the instrument. The diaphragm at K is movable so that it can be made to coincide with the image of the staff. The focal length f_1 of the object glass is arbitrary, and the focal length f_2 of the anallattic lens is determined from an equation of condition between c, d, f_1, and f_2. The image of the staff ST would be formed by the object glass at H, at a distance v_1 from the object glass, were it not that the rays, after passing through the object glass, are received by the anallattic lens and the image of the staff is formed at K on the wire diaphragm, which is slid in the tube till it coincides with the position of the image. The image at K is viewed by an eye-piece in the usual way. Let T be the point where the image of the staff is cut by the central wire of the diaphragm, and S the point where the image is cut by one of the outer wires of the diaphragm. If θ and ϕ be the angles subtended by ST at the object glass and at the point O respectively, and if i be the height of the image at K, h the height of the virtual image at H, then by elementary geometry and from optical considerations, we obtain

$$i=\frac{u'f_1f_2}{u'(f_1-d+f_2)-\{cf_1-(c+f_1)(d-f_2)\}}\cdot\tan\phi$$

Let f_2 be made such that $cf_1-(c+f_1)(d-f_2)=0$, the equation of condition above mentioned. Then $f_2=\{d(c+f_1)-cf_1\}/(c+f_1)$.

And $i=\dfrac{f_1f_2}{f_1-d+f_2}\cdot\tan\phi=\dfrac{d(c+f_1)-cf_1}{f_1}\cdot\tan\phi$.

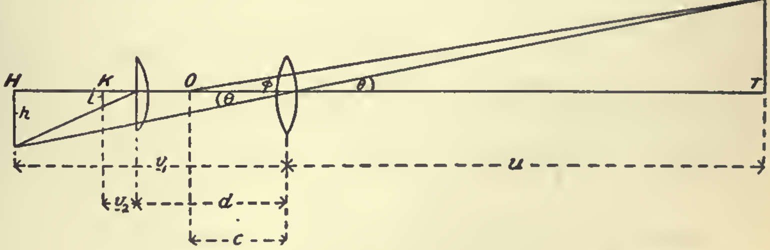

FIG. 6.

Therefore all the readings of the staff which would be given by the outer wire of the diaphragm will lie on the line OS (for all of which ϕ is the same), and the distance from O along OT will be proportional to the reading on the staff. Thus if the staff be suitably graduated, the distance from O can be immediately deduced from the reading. Also, as before, if the telescope be inclined at an angle α to the horizontal, the distance OT inferred from the number of graduations in ST must be multiplied by $\cos^2 \alpha$ to give the horizontal distance of O from T, and the horizontal distance so obtained must be multiplied by $\tan \alpha$ to obtain the vertical distance of T from O.

The inconvenience of the reduction work necessary to obtain the horizontal and vertical distances produced the Wagner-Feunel tacheometer, by which the distances can be read directly from the instrument. As is seen from fig. 7, three scales are provided, to measure the inclined distance, the horizontal distance, and the vertical distance respectively. All three are arranged in a plane parallel to the plane in which the telescope turns. The inclined scale is attached to the telescope exactly parallel to its line of collimation, and moves with it. The horizontal scale is fixed to the upper horizontal plate of the theodolite. The vertical scale is on the vertical edge of a right-angled triangle, which can be slid along on the top of the horizontal scale. The inclined scale carries a slide which is provided with two verniers. One of these is parallel to the inclined scale, and is for the purpose of setting off on the scale (in terms of the divisions on the scale) the inclined distance of the staff from the axis of rotation of the telescope. The other turns on a pivot whose centre is accurately in the edge of the inclined scale at the point where the zero division of the inclined vernier

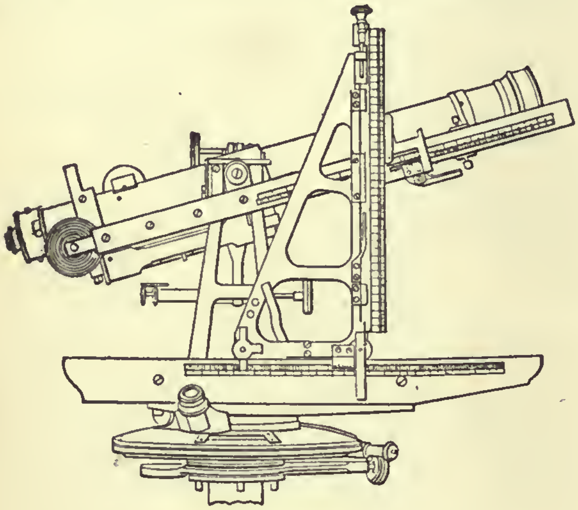

FIG. 7.

cuts the edge, and is for the purpose of reading the vertical scale; it can be turned on its pivot so as to be vertical whatever may be the inclination of the telescope. Moreover, since the distance from the centre of the pivot to the zero of the vernier is always constant and known, the vertical scale can be graduated so that the reading of the vernier gives the height (in terms of the division on the scale) of the staff above the axis of rotation of the telescope. The horizontal scale attached to the horizontal plate of the theodolite is read by means of a vernier carried by the triangle. To ascertain the horizontal and vertical distances of the point on the staff which is cut by the middle wire in the diaphragm of the telescope from the rotation axis of the telescope, the inclined distance of the point on the staff is read by means of the wires, as in Porro's tacheometer. This distance (in terms of the divisions) is then set off on the inclined scale by means of the inclined vernier, and the vertical scale on the triangle is moved up to the vertical vernier, which is adjusted to its edge. With proper graduation of the horizontal and vertical scales the horizontal and vertical distances can be at once read off on the scales. This method, however, requires that the staff be held so that its face is perpendicular to the line of sight, which is more troublesome than holding the staff vertical.

TACHIENLU, a town of China, in the province of Sze-ch 'uen. It is the great tea mart for Tibet, and from Tachienlu the two trade-routes. the Gya lam and the Chang lam, diverge, the former to Ladakh and the latter to Kashgar.

TACHYLYTES, or TACHYLITES (from Gr. *ταχύς*, swift, *λύειν*, to dissolve, meaning "easily fused," though some have erroneously interpreted it as "easily soluble in acids"), in petrology, the vitreous forms of the basic igneous rocks; in other words, they are basaltic obsidians. They are black in colour, dark brown in the thinnest sections, with a resinous lustre and the appearance of pitch, often more or less vesicular and sometimes spherulitic. They are very brittle, and break down readily under the hammer. Small crystals of felspar or of olivine are sometimes visible in them with the unaided eye. All tachylytes weather rather easily, and by oxidation of their iron become dark brown or red. Three modes of occurrence characterize this rock. In all cases they are found under conditions which imply rapid cooling, but they are much less common than acid volcanic glasses (or obsidians), the reason being apparently that the basic rocks have a stronger tendency to crystallize, partly because they are more liquid and the molecules have more freedom to arrange themselves in crystalline order.

The fine scoria ashes or "cinders" thrown out by basaltic volcanoes are often spongy masses of tachylyte with only a few larger crystals or phenocrysts imbedded in black glass. Such tachylyte bombs and scoria are frequent in Iceland, Auvergne, Stromboli, Etna, and are very common also in the ash beds or tuffs of older date, such as occur in Skye, Midlothian and Fife, Derbyshire, and elsewhere. Basic pumices of this kind are exceedingly wide-spread on the bottom of the sea, either dispersed in the "red clay" and other deposits or forming layers coated with oxides of manganese, precipitated on them from the sea water. These tachylyte fragments, which are usually much decomposed by the oxidation and hydration of their ferrous compounds, have taken on a dark red colour. This altered basic glass is known as "palagonite"; concentric bands of it often surround kernels of unaltered tachylyte, and are so soft that they are easily cut with a knife. In the palagonite the minerals also are decomposed, and are represented only by pseudomorphs. The fresh tachylyte glass, however, often contains lozenge-shaped crystals of plagioclase felspar and small prisms of augite and olivine, but all these minerals very frequently occur mainly as microlites or as beautiful skeletal growths with sharply-pointed corners or ramifying processes. Palagonite tuffs are found also among the older volcanic rocks. In Iceland a broad stretch of these rocks, described as "the palagonite formation," is said to cross the island from south-west to north-east. Some of these tuffs are fossiliferous; others are intercalated with glacial deposits. The lavas with which they occur are mostly olivine-basalts. Palagonite tuffs are found in Sicily, the Eifel, Hungary, Canary Islands, &c.

A second mode of occurrence of tachylyte is in the form of lava flows. Basaltic rocks often contain a small amount of glassy ground-mass, and in the limburgites this becomes more important and conspicuous, but vitreous types are far less common in these than in the acid lavas. In the Hawaiian Islands, however, the volcanoes have poured out vast floods of black basalt, containing felspar, augite, olivine, and iron ores in a black glassy base. They are highly liquid when discharged, and the rapid cooling which ensues on their emergence to the air prevents crystallization taking place completely. Many of them are spongy or vesicular, and their upper surfaces are often exceedingly rough and jagged, while at other times they assume rounded wave-like forms on solidification. Great caves are found where the crust has solidified and the liquid interior has subsequently flowed away, and stalactites and stalagmites of black tachylyte adorn the roofs and floors. On section these growths show usually a central cavity enclosed by walls of dark brown glass in which skeletons and microliths of augite, olivine and felspar lie imbedded. From the crater of Kilauea thin clouds of steam rise constantly, and as the bubbles of vapour are liberated from the molten rock they carry into the air with them thin fibres of basalt which solidify at once and assume the form of tachylyte threads. Under the microscope they prove to be nearly completely glassy with small circular air vesicles sometimes drawn out to long tubes. Only in the Hawaiian Islands are glassy basaltic lavas of this kind at all common.

A third mode of occurrence of tachylyte is as the margins and thin offshoots of dikes or sills of basalt, dolerite and diabase. They are sometimes only a fraction of an inch in thickness, resembling a thin layer of pitch or tar on the edge of a crystalline dolerite dike, but veins several inches thick are sometimes met with. In these situations tachylyte is rarely vesicular, but it often shows very pronounced fluxion banding accentuated by the presence of rows of spherulites which are visible as dark brown rounded spots. The spherulites have a distinct radiate structure and sometimes exhibit zones of varying colour. The non-spherulitic glassy portion is sometimes perlitic and these rocks are always brittle. The commonest crystals are olivine, augite and felspar, with swarms of minute dusty black grains of magnetite. At the extreme edges the glass is often perfectly free from crystalline products, but it merges rapidly into the ordinary crystalline dolerite, which in a very short distance may contain no vitreous base whatever. The spherulites may form the greater part of the mass, they may be a quarter of an inch in diameter and are occasionally much larger than this. These coarsely spherulitic rocks pass over into the variolites (*q.v.*) by increasing coarseness in the fibres of their spherulites, which soon become recognizable as needles of felspar or feathery growths of augite. The ultimate product of decomposition in this case also is a red palagonitic substance, but owing to the absence of steam cavities the tachylyte selvages of dikes are more often found in a fresh state than the basic lapilli in ash-beds. Many occurrences of basaltic pitchstones have been reported from Skye, Mull, and the western part of Scotland; they are found also in connexion with the intrusive dolerite sills of the north of England and the centre of Scotland. In the Saar district of Germany similar rocks occur, some of which have been described as weisselbergites (from Weisselberg).

Other localities for tachylytes of this group are Nassau, Silesia and Sweden.

The chemical composition of some of the rocks of this group is indicated by the analyses given below:—

(J. S. F.)

TACITUS, CORNELIUS (*c.* 55–120), Roman historian. Tacitus, who ranks beyond dispute in the highest place among men of letters of all ages, lived through the reigns of the emperors Nero, Galba, Otho, Vitellius, Vespasian, Titus, Domitian, Nerva and Trajan. All we know of his personal history is from allusions to himself in his own works, and from eleven letters addressed to him by his very intimate friend, the younger Pliny. The exact year of his birth is a matter of inference, but it may be approximately fixed near the close of the reign of Claudius. Pliny indeed, though himself born in 61 or 62, speaks of Tacitus and himself as being "much of an age,"[1] but he must have been some years junior to his friend, who began, he tells us, his official life under Vespasian,[2] no doubt as quaestor, and presumably tribune or aedile under Titus (80 or 81), at which time he must have been twenty-five years of age at least. Of his family and birthplace we know nothing certain; we can infer nothing from his name Cornelius, which was then very widely extended; but the fact of his early promotion seems to point to respectable antecedents, and it may be that his father was one Cornelius Tacitus, who had been a procurator in one of the divisions of Gaul, to whom allusion is made by the elder Pliny in his *Natural History* (vii. 76). But it is all matter of pure conjecture, as it also is whether his "praenomen" was Publius or Gaius. The most interesting facts about him to us are that he was an eminent pleader at the Roman bar, that he was an eye-witness of the "reign of terror" during the last three years of Domitian, and that he was the son-in-law of Julius Agricola. This honourable connexion, which testifies to his high moral character, may very possibly have accelerated his promotion, which he says[3] was begun by Vespasian, augmented by Titus, and still further advanced by Domitian, under whom we find him presiding as praetor at the celebration of the secular games in 88, and a member of one of the old priestly colleges, to which good family was an almost indispensable passport. Next year, it seems, he left Rome, and was absent till 93 on some provincial business, and it is possible that in these four years he may have made the acquaintance of Germany and its peoples. His father-in-law died in the year of his return to Rome. In the concluding passage of his *Life of Agricola* he tells us plainly that he witnessed the judicial murders of many of Rome's best citizens from 93 to 96, and that being himself a senator he felt almost a guilty complicity in them. With the emperor Nerva's accession his life became bright and prosperous, and so it continued through the reign of Nerva's successor, Trajan, he himself, in the opening passage of his *Agricola*, describing this as a "singularly blessed time," but the hideous reign of terror had stamped itself ineffaceably on his soul, and when he sat down to write his *History* he could see little but the darkest side of imperialism. To his friend the younger Pliny we are indebted for the little we know about his later life. He was advanced to the consulship in 97, in succession to a highly distinguished man, Verginius Rufus, on whom he delivered in the senate a funeral eulogy. In 99 he was associated with Pliny in the prosecution of a great political offender, Marius Priscus, under whom the provincials of Africa had suffered grievous wrongs. The prosecution was successful, and both Tacitus and Pliny received a special vote of thanks from the senate for their conduct of the case. It would seem that Tacitus lived to the close of Trajan's reign, as he seems[4] to hint at that emperor's extension of the empire by his successful Eastern campaigns from 115 to 117. Whether he outlived Trajan is matter of conjecture. It is worth noticing that the emperor Tacitus in the 3rd century claimed descent from him, and directed that ten copies of his works should be made every year and deposited in the public libraries. He also had a tomb built to his memory, which was destroyed by order of Pope Pius V. in the latter part of the 16th century.

Pliny, as we see clearly from several passages in his letters, had the highest opinion of his friend's ability and worth. He consults him about a school which he thinks of establishing at Comum (Como), his birthplace, and asks him to look out for suitable teachers and professors. And he pays[5] him the high compliment, "I know that your *Histories* will be immortal, and this makes me the more anxious that my name should appear in them."

The following is a list of Tacitus's remaining works, arranged in their probable chronological order, which may be approximately inferred from internal evidence:—(1) the *Dialogue on Orators*, about 76 or 77; (2) the *Life of Agricola*, 97 or 98; (3) the *Germany*, 98, published probably in 99; (4) the *Histories* (*Historiae*), completed probably by 115 or 116, the last years of Trajan's reign (he must have been at work on them for many years); (5) the *Annals*, his latest work probably, written in part perhaps along with the *Histories*, and completed subsequently to Trajan's reign, which he may very well have outlived.

The *Dialogue on Orators* discusses, in the form of a conversation which Tacitus professes to have heard (as a young man) between some eminent men at the Roman bar, the causes of the decay of eloquence under the empire. There are some interesting remarks in it on the change for the worse that had taken place in the education of Roman lads. The style of the *Dialogue* is far more Ciceronian than that of Tacitus's later work, and critics have attributed it to Quintilian; but its genuineness is now generally accepted. It is noticeable that the mannerisms of Tacitus appear to develop through his lifetime, and are most strongly marked in his latest books, the *Annals*.

The *Life of Agricola*, short as it is, has always been considered an admirable specimen of biography. The great man with all his grace and dignity is brought vividly before us, and the sketch we have of the history of our island under the Romans gives a special interest to this little work.

The *Germany*, the full title of which is "Concerning the geography, the manners and customs, and the tribes of Germany," describes with many suggestive hints the general

[1] Pliny, *Epp.* vii. 20. [2] *Hist.* i. 1. [3] *Ibid.*

[4] *Ann.* ii. 61; iv. 4. [5] *Epp.* vii. 33.

character of the German peoples, and dwells particularly on their fierce and independent spirit, which the author evidently felt to be a standing menace to the empire. The geography is its weak point; much of this was no doubt gathered from vague hearsay. Tacitus dwells on the contrast between barbarian freedom and simplicity on the one hand, and the servility and degeneracy of Roman life on the other.

The *Histories*, as originally composed in twelve books, brought the history of the empire from Galba in 69 down to the close of Domitian's reign in 97. The first four books, and a small fragment of the fifth, giving us a very minute account of the eventful year of revolution, 69, and the brief reigns of Galba, Otho and Vitellius, are all that remain to us. In the fragment of the fifth book we have a curious but entirely inaccurate account of the Jewish nation, of their character, customs and religion, from a cultivated Roman's point of view, which we see at once was a strongly prejudiced one.

The *Annals*—a title for which there is no ancient authority, and which there is no reason for supposing Tacitus gave distinctively to the work—record the history of the emperors of the Julian line from Tiberius to Nero, comprising thus a period from A.D. 14 to 68. Of these, nine books have come down to us entire; of books v., xi. and xvi. we have but fragments, and the whole of the reign of Gaius (Caligula), the first six years of Claudius, and the last three years of Nero are wanting. Out of a period of fifty-four years we thus have the history of forty years.

The principal MSS. of Tacitus are known as the "first" and "second" Medicean—both of the 10th or 11th centuries. The first six books of the *Annals* exist nowhere but in the "first Medicean" MS., and an attempt was made in 1878 to prove that the *Annals* are a forgery by Poggio Bracciolini, an Italian scholar of the 15th century, but their genuineness is confirmed by their agreement[1] in various minute details with coins and inscriptions discovered since that period. Moreover, Ruodolphus, a monk, writing in the 9th century, shows that he is acquainted with a MS. of Tacitus containing at least the two first books. Add to this the testimony of Jerome that Tacitus wrote in thirty books the lives of the Caesars and the evidence of style, and there can be no doubt that in the *Annals* we have a genuine work of Tacitus.

Much of the history of the period described by him, especially of the earlier Caesars, must have been obscure and locked up with the emperor's private papers and memoranda. As we should expect, there was a vast amount of floating gossip, which an historian would have to sift and utilize as best he might. Tacitus, as a man of good social position, no doubt had access to the best information, and must have talked matters over with the most eminent men of the day. There were several writers and chroniclers, whom he occasionally cites but not very often; there were memoirs of distinguished persons—those, for example, of the younger Agrippina, of Thrasea, and Helvidius. There were several collections of letters, like those of the younger Pliny; a number, too, of funeral orations; and the "acta senatus" and the "acta populi" or "acta diurna," the first a record of proceedings in the senate, the latter a kind of gazette or journal. Thus there were the materials for history in considerable abundance, and Tacitus was certainly a man who knew how to turn them to good account. He has given us a striking, and on the whole doubtless a true, picture of the empire in the 1st century. The rhetorical tendency which characterizes the "silver age" of Roman literature, gives perhaps exaggerated expression to his undoubtedly strong sense of the badness of individual emperors, but he assuredly wrote with a high aim, and we may accept his own account of it: "I regard[2] it as history's highest function to rescue merit from oblivion, and to hold up as a terror to base words and actions the reprobation of posterity." He is convinced of the degeneracy of the age, though it be relieved by the existence of truly noble virtues: and he connects this degeneracy more or less directly with the imperial régime. But it is difficult to dogmatize as to Tacitus's political ideals. He is primarily concerned rather with ethics than with politics; though he may feel that the world is out of joint—with whatever sentimental sympathy he may regard the age of "liberty," and admire the heroic epoch of the republic—yet he appears to realize that the empire is a practical necessity, and to the provinces even a benefit. Like the Stoics, with whom otherwise he has little in common, he censures rather individual rulers than the imperial system. But "the key to the interpretation of Tacitus," it has been well said,[3] "is to regard him as a moralist rather than a politician." Perhaps the strongest work in the *Annals* and *Histories* is the delineation of character.

Tacitus gives us no certain clue to his religious belief. His expressions of opinion about the government of the universe are difficult to reconcile with each other. There seems to have been a strange tinge of superstition about him, and he could not divest himself of some belief[4] in astrology and revelations of the future through omens and portents, though he held these were often misunderstood and misinterpreted by charlatans and impostors. On the whole he appears to have inclined to the philosophical theory of "necessitarianism," that every man's future is fixed from his birth; but we must not fasten on him any particular theory of the world or of the universe. Sometimes he speaks as a believer in a divine overruling Providence, and we may say confidently that with the Epicurean doctrine he had no sort of sympathy.

Tacitus's style is discussed in the article LATIN LANGUAGE. Whatever judgment may be passed on it, it is certainly that of a man of genius, and cannot fail to make a deep impression on the studious reader. Tacitean brevity has become proverbial, and with this are closely allied an occasional obscurity and a rhetorical affectation which his warmest admirers must admit. He has been compared to Carlyle: and both certainly affect singularity of expression. But they are alike only in the brevity of sentences; and the brevity of Carlyle is not that of an artist in epigram. Tacitus was probably never a popular author; to be understood and appreciated he must be read again and again, or the point of some of his acutest remarks will be quite missed.

Tacitus has been many times translated, in spite of the very great difficulty of the task; the number of versions of the whole or part is stated as 393.

Murphy's translation (we should call it a paraphrase) was for long one of the best known; it was published early in the 19th century. On this was based the so-called Oxford translation, published by Bohn in a revised edition. Messrs Church and Brodribb's translation, and Professor Ramsay's (1904) (the latter of *Annals* i.–iv.) are much better. The best known foreign translation is Davanzati's (Italian), printed about 1600 and frequently re-published. The French versions by Louandre and Burnouf (about the middle of the last century) are also good. Among the very numerous modern commentaries, the most important are Ruperti's (1839); Orelli's (1859: the *Histories*, *Germania*, *Agricola*, and *Dialogues* were revised and re-edited by Meiser and Andersen between 1877 and 1895); Ritter's (1864); Nipperdey's (1879); Heräus's (*Histories*, 1885); Furneaux's (*Annals*, i.–vi., 1884; xi.–xvi., 1891; *Germania*, 1894); Spooner's (*Histories*, 1891). The last two editors' introductions are particularly useful. Of works relating to Tacitean Latinity, Draeger's *Syntax und Stil des Tacitus* is the best.

(W. J. B.; A. D. G.).

TACITUS, MARCUS CLAUDIUS, Roman emperor from the 25th of September A.D. 275 to April 276, was a native of Interamna (Terni) in Umbria. In the course of his long life he held various civil offices, including that of consul in 273, with universal respect. Six months after the assassination of Aurelian he was chosen by the senate to succeed him, and the choice was cordially ratified by the army. During his brief reign he set on foot some domestic reforms, and sought to revive the authority of the senate, but, after a victory over the Goths in Cilicia, he succumbed to hardship and fatigue (or was slain by his own soldiers) at Tyana in Cappadocia. Tacitus, besides being a man of immense wealth (which he bequeathed to the state),

had considerable literary culture, and was proud to claim descent from the historian, whose works he caused to be transcribed at the public expense and placed in the public libraries. Tacitus possessed many admirable qualities, but his gentle character and advanced age unfitted him for the throne in such lawless times.

TACNA, a northern province of Chile, in dispute with Peru from 1893 onwards, bounded N. by Peru, E. by Bolivia, S. by Tarapaca, and W. by the Pacific. Area, 9251 sq. m. Pop. (1895) 24,160. It belongs to the desert region of the Pacific coast, and is valuable because of its deposits of nitrate of soda and some undeveloped mineral resources. There are a few fertile spots near the mountains, where mountain streams afford irrigation and potable water, and support small populations, but in general Tacna is occupied for mining purposes only. None of its streams crosses the entire width of the province; they are all lost in its desert sands. The climate is hot, and earthquakes are frequent and sometimes violent. There is one railway in the province, running from the city of Tacna to Arica (*q.v.*), and in 1910 another from Arica to La Paz, Bolivia, was under construction by the Chilean government. The province consists of two departments, Tacna and Arica, which once formed part of the Peruvian department of Moquegua. Its capital is Tacna (pop. 1895, 9418; 1902, estimated 11,504), a small inland town 48 m. by rail from Arica, in a fertile valley among the foothills of the Andes. Existence is made possible in this oasis by a small mountain stream, also called Tacna, which supports a scanty vegetation. The town owes its existence to the Bolivian trade from La Paz and Oruro, and is the residence of a number of foreign merchants. Tacna was captured by a Chilean force under General Baquedano on the 27th of May 1880.

At the close of the war between Chile and Peru (1879–1883), the terms of the treaty of Ancon (signed by representatives of the two countries on the 20th of October 1883) were practically dictated by Chile, and by one of the provisions the Peruvian provinces of Tacna and Arica were to be occupied and exploited by Chile for a period of ten years, when a plebiscite should be taken of their inhabitants to determine whether they would remain with Chile or return to Peru, the country acquiring the two provinces in this manner to pay the other $10,000,000. At the termination of the period Peru wished the plebiscite to be left to the original population, while Chile wanted it to include the large number of Chilean labourers sent into the province. Chile refused to submit the dispute to arbitration, and it remained unsettled. Meanwhile Chile expelled the Peruvian priests, and treated the province more like a conquered territory than a temporary pledge.

TACOMA, a city and sub-port of entry, and the county-seat of Pierce county, Washington, U.S.A., on Commencement Bay of Puget Sound, at the mouth of Puyallup river, about 80 m. from the Pacific coast, and about 23 m. S.S.W. of Seattle. Pop. (1890) 36,006; (1900) 37,714, of whom 11,032 were foreign-born (including 1603 Swedes, 1534 English-Canadians, 1474 Norwegians, 1424 Germans, and 1323 English; (1910, U.S. census) 83,743. Tacoma is served by the Northern Pacific, the Chicago, Milwaukee & Puget Sound, and the Tacoma Eastern railways; the Chicago, Burlington & Quincy railway operates through trains to and from Missouri river points and Tacoma, over the Northern Pacific tracks, which are also used by the Great Northern and Oregon & Washington railways. There is electric railway connexion with Seattle. Tacoma is the starting-point of steamship lines to Alaska, to San Francisco, and to Seattle, Port Townsend, Olympia, Victoria, and other ports on Puget Sound. There are trans-oceanic lines to Japan and China, to the Philippines and Hawaii, and to London, Liverpool and Glasgow, by way of the Suez Canal. The city is situated on an excellent harbour and has 25 m. of waterfront. From the tidelands the city site slopes gradually to a plateau about 300 ft. high, commanding fine views of Puget Sound and its wooded islands, and parts of the Cascade and Olympic ranges. Tacoma is the seat of Whitworth College (1890, Presbyterian), the University of Puget Sound (1903, Methodist Episcopal), the Annie Wright Seminary (1884), a boarding and day school for girls, and the Pacific Lutheran Academy and Business College. The Tacoma High School has an excellent stadium for athletic contests, seating 25,000. The city has a Carnegie library (1899), with about 51,000 volumes. Among other public buildings are the court house, the city hall, in which are the rooms of the State Historical Society (organized, 1891; incorporated, 1897); the Federal Building; an armoury; the Chamber of Commerce, and several fine churches. The Ferry Museum, founded by Clinton P. Ferry, has interesting historical and ethnological collections. In 1910 the city had seven public parks (1120 acres), including Point Defiance, a thickly wooded park (about 640 acres), and, in the centre of the city, Wright Park, in which is the Seymour Conservatory. Tacoma is a sub-port of entry in the Puget Sound Customs district (of which Port Townsend is the official port), which is second only to San Francisco on the Pacific coast in the volume of foreign trade. The city has a large jobbing trade, a coal supply from rich deposits in Pierce county, and abundant water-power from swift mountain streams, which is used for generating electricity for municipal and industrial use. In 1900 and in 1905 Tacoma ranked second among the cities of the state in the value of factory products. Lead smelting and refining (by one establishment) was the most important industry in 1905; lumber, timber and planing mill products, valued at $3,407,951, were produced in that year, and flour and grist mill products, valued at $2,293,587. Other important manufactures were furniture, ships and boats, railway cars (the Chicago, Milwaukee & Puget Sound and the Northern Pacific systems having shops here), engines, machinery, shoes, water pipes, preserves and beer. In 1905 the total value of the factory products was $12,501,816, an increase of 121·4% since 1900. The assessed property valuation of the city in 1909 was $54,226,261, being about 42% of the actual valuation.

The site of Tacoma was visited by Captain George Vancouver in 1792; Commencement Bay was surveyed for the United States government by Lieutenant Charles Wilkes in 1841, and the present city was founded by General Morton Matthew McCarver in 1868 and was at first called Commencement City. That name was soon changed to Tacoma, said to be a corruption of *Ta-ho-ma* or *Ta-ho-bet*, Indian terms meaning "greatest white peak," the name of the peak (14,526 ft.), also called Mt. Rainier, about 50 m. S.E. of the city. General McCarver's original plat included what is now the first ward of the city, and is called the Old Town. In 1873 the Northern Pacific railway (completed in 1887) established its terminal on Commencement Bay, and named it New Tacoma. A town government was formed in 1874, the place became the county-seat in 1880, and in 1883 the two "towns" were consolidated and incorporated as a city under the name Tacoma. In 1909 a new city charter was adopted under which the city government is vested in five commissioners (one of whom acts as mayor), each in charge of a city department.

TACTICS (Gr. *τακτική*, sc. *τέχνη*, from *τάσσειν*, to arrange in order of battle).[1] It may perhaps seem superfluous at the present time to emphasize the distinction between strategy and tactics. Moreover, definitions are rarely quite satisfactory, for they can seldom be perfectly clear and at the same time perfectly comprehensive. Yet, since it is necessary that the parties to any discussion should have some common starting-point, it will be as well to begin by stating exactly what is meant to be included under the heading of this article.

Strategy (*q.v.*) is the art of bringing the enemy to battle on terms disadvantageous to him. Combined, or to use the phraseology of the Napoleonic era, "grand" tactics are the

[1] Unlike the French *tactique*, the German *Taktik*, and indeed all other forms, the English word is invariably treated as a plural noun.

methods employed for his destruction by a force of all arms, that is, of infantry (*q.v.*), artillery (*q.v.*) and cavalry (*q.v.*). Each of these possesses a power peculiar to itself, the full development of which depends to a greater or less degree upon the aid and co-operation of the other two. Now it is quite evident that the only force which can ensure this co-operation, and can produce harmonious working between the various components of that complex machine, a modern army, is the will-power of the supreme commander. It is, then, the sphere of the higher commander on the day of battle which is generally expressed by the term "combined tactics," and which will be dealt with in this article. Yet it must not be understood that because the term higher, or supreme, commander is used that the theory of combined tactics may be safely neglected by those soldiers whose ambitions or opportunities do not seem to lead to that position. In the British Army more than in any other, as the South African war showed, a comparatively junior officer may at any moment find himself placed in command of a mixed force of all arms, without any previous practical knowledge of how it should be handled. It will not then be possible to make the best use of such opportunities by the uneducated light of nature, and such theoretical knowledge as may have been gleaned from books and matured by thought will be of great value.

Necessity of study.

It is of the first importance that the commander of a mixed force should know exactly the powers and limitations of the units under his control. Should he not be a master of his profession, he will at times demand more from his subordinates than they can reasonably be expected to perform; at other times he will miss his chances by ignorance of their capabilities. An uneducated commander may indeed be likened to an indifferent mechanic, who sometimes places an undue strain upon the engine he is supposed to control, and sometimes allows its precious powers to run to waste.

There is, however, a still stronger reason why all officers should study the art of grand tactics. In every battle situations arise of which the issue is decided by the promptitude and efficiency of the co-operation between the three arms. At such moments, an officer in charge of a battery of artillery, or of a squadron of cavalry, may find an opportunity of rendering valuable aid to his own infantry; and a knowledge of the tactics and training of the other arms may then be essential, for it will probably be necessary to act without instructions from superior authority.

But although the importance of studying tactics may be readily allowed, there would appear to be considerable diversity of opinion as to the best method of conducting that study. It is often confidently asserted that tactics cannot be learnt from books; and in support of this theory it is customary to adduce Napoleon's well-known statement that tactics change every ten years. But if we examine the matter more closely, it will become evident that the changes which the great captain had in his mind were those of formations, due principally to improved weapons, rather than of the principles upon which combined tactics are based. Indeed, it could hardly be otherwise, for military history furnishes many instances of great battles which have been fought out on exactly the same lines, although separated in point of time by many centuries. The great similarity between Rossbach (*q.v.*), Austerlitz (*q.v.*) and Salamanca (*q.v.*) has often been quoted since Napoleon first drew attention to it, but a great deal more remarkable and instructive is the similarity between the battle on the Metaurus, which dealt the final blow to the hopes of Carthage in Italy, and Marlborough's masterpiece, the battle of Ramillies (*q.v.*). In both cases the battle was lost through faulty dispositions before it had been begun. In both cases the ultimate loser took up a position behind a stream, thereby losing his mobility and voluntarily surrendering the initiative to an enemy who was not slow to take advantage of it. Precisely the same error was committed time after time by the Austrian generals who fought against Frederick, notably at Leuthen (see SEVEN YEARS' WAR), a battle closely resembling both Ramillies and the Metaurus. Coming to a later date, we find the same error committed, with of course precisely the same result, in Manchuria, where the Russian generals repeatedly surrendered the initiative to their enterprising opponents, and allowed them to dictate the course of battle. It must not, however, be understood from this that no commander should ever stand upon the defensive; rather it is meant that we should learn from history the proper method of doing so. This we cannot do better than by studying Wellington's battles in the Peninsula, for never have tactics been brought to higher perfection. Although frequently compelled to adopt the defensive, he never surrendered the conduct of the battle to his enemy. Even when surprised and taken at great disadvantage by Soult at Maya (see PENINSULAR WAR), it can be seen how, while lesser men would have been content to reinforce the threatened points, Wellington's one thought was to discover where he could deal the most effective blow. Nearly a hundred years later and in a theatre of war many thousands of miles away, a very similar battle was fought out by Kuropatkin and Oyama, though on a vastly greater scale.

Continuity of military history.

But history teaches us more than the methods of the great captains; for from it we may learn those changes which have been introduced into both organization and tactics by the improved weapons which science has placed in our hands, and thence the tactician may deduce the changes of the future. Just as the "Old Dessauer" foresaw the advantage which the iron ramrod would give to the Prussian infantry, and as Wellington perceived that improved firearms would render possible the extended lines he adopted, so may the great generals of the future learn those lessons which are only brought home to others through the dire ordeal of battle. From the days of the long-bow to those of the Lee-Metford rifle, the changes in tactics have been brought about by the development of fire. It is therefore only natural that the introduction of small-bore rifles, quick-firing artillery, and smokeless powder should have revolutionized many of our ideas. Before the invention of the breech-loader and the rifled cannon, the three arms of the service employed very different methods of combat. The infantry depended principally on the bayonet, the cavalry on the lance or sabre, the artillery on fire. Now there is practically but one method common to all arms whether in attack or defence. The bayonet and the sabre still have their part to play; but in almost every phase of the combat their importance is diminishing, and infantry and cavalry must depend more and more upon fire to compass the enemy's overthrow. All the preliminary movement and manoeuvres have but one end in view, the development of fire in greater volume and more effectively directed than that of the opposing force; for it is "superiority of fire" that prepares the ground for the final decision.

Fire power.

Side by side with the improvement in firearms there has come another great change which, on the continent of Europe at all events, has had a marked effect on modern tactics. This is the improvement in communications, which has alone made it possible to use the vast numbers with which great battles have recently been fought. Without railways the power which universal service has placed in the hands of the generals of the 20th century could never have been fully developed, for the men could neither have been conveyed to the theatre of operations, nor could they have been fed even supposing they had been got there. Now all this is altered, and the first step towards the attainment of superiority of fire will be to bring as many men as possible on to the field of battle; the second step will be to place them in the position from which they can use their weapons to the very best advantage. From these premises it is not difficult to foresee the type of battle which will prevail, until some new discovery changes the military systems of the world. In the future, as in the past, it will be the duty of the strategist to mass superior numbers at the decisive point; but so soon as this has been effected there is only one method by which the tactician will be able to follow up the advantage. That is by bringing

Modern conditions.

more rifles into action than his opponent is able to do. From this it follows that the enveloping action will be the usual form of battle; and that although the extent of front may not always be so great, in proportion to the numbers engaged, as on the battlefields of South Africa or even of Manchuria, the general tendency of modern invention will undoubtedly be to increase the area of the battlefield.

If then we are right in supposing that the front of an army in action will cover many miles of country, it necessarily follows that in approaching the field many roads will be used. Here the duties of the cavalry will begin; for the commander who can discover earliest the approaches by which the flank detachments of his opponent are moving, is obviously in the best position to form his plans for envelopment. Here we are verging upon the strategic use of cavalry; but under modern conditions the tactical use of that arm is almost merged in the strategical use. No doubt it has always been the object of the wise commander to attain his enemy's flank; yet, since, owing to the increased range of small-bore rifles, turning movements like those which formed such a marked feature of Frederick the Great's battles can no longer be made after the infantry troops have come into contact, they must be prepared as soon as the necessary information has been obtained. Moreover, nothing must be left to chance, for it can hardly be denied that if the battle of Gravelotte were to be fought again to-morrow, the failure to locate the right flank of the French army would have even more serious consequences than were actually the case (see METZ: *Battles of 1870*). Such mistakes can only be avoided by obtaining good information, and thus it will be seen that the chances of bringing off a successful converging attack are greatly in favour of the commander who is best served by his cavalry. But, as the opposing forces draw near, a gradual change comes over the duties of the mounted arm, for it must then protect the troops in rear from observation, so that the preparations for envelopment may be concealed. To this end the occupation of points of tactical vantage, such as hills, woods and villages, behind which the main army can deploy or the outflanking columns march in security, becomes its chief aim. In the next stage, *i.e.*, when one or other army is forced to stand on the defensive, reconnaissance of the position held will be the duty of the cavalry of the attack.

Cavalry.

So far its functions are clear enough, but when the preparations for the infantry attack have been completed we have practically nothing to guide us. Unfortunately the two most recent wars, in South Africa and Manchuria, have taught us but little of the handling of cavalry in battle. In South Africa the peculiar characteristics of the Boers gave no scope for cavalry action; while in Manchuria the theatre of operations was practically a defile between the mountains and the Liao river, which afforded no room for manoeuvre. With regard to the handling of cavalry in conjunction with the other arms there is, therefore, more room for diversity of opinion than is the case with either infantry or artillery. Time alone will show the real capabilities of the cavalry of to-day, and the opening battles of the next great campaign in Europe will bring about many changes. Meanwhile such experience as we have to guide us seems to indicate that the development of fire has rendered cavalry, even when highly trained in the use of the rifle, less capable of acting independently against infantry than it was formerly. Throughout the war in Manchuria, we constantly find the Russian cavalry reconnaissance checked by Japanese infantry; and on the other hand the weak Japanese cavalry closely supported by infantry was fairly effective. The circumstances were of course peculiar, but the inference appears to be that unsupported mounted troops cannot be expected to achieve important results except when acting against similar bodies of the enemy; that is to say, under conditions which fall outside the province of combined tactics. Moreover, since well-posted infantry can easily hold in check greatly superior numbers of cavalry, it would certainly seem that wide tactical movements, intended to threaten the enemy's line of retreat, are more likely than not to result in prodigal waste of strength. This being the case it would seem that the best use of cavalry on the battlefield will be on the flanks of, and in close touch with, the infantry, where each arm can render support to the other. On the defensive the tactical action of cavalry is not less important than on the offensive. Accompanied and strengthened by horse artillery it may occupy tactical points either on the flanks of the main position or thrown out well to the front. Aided by smokeless powder, magazine rifles and quick-firing guns, numbers may be concealed and the attacking enemy may be induced to deploy his troops and to reveal his movements prematurely. Should he do so, much of his advantage will be gone, for the defender will be greatly helped in his preparations for the counter-attack, the most effective weapon at his command.

But when at last the slower moving bodies of infantry and artillery come into contact, the battle enters upon a new phase. It has long been recognized that the first step towards the attainment of fire superiority over a vigilant enemy is a vigorous artillery bombardment. For many years this action of the artillery was regarded merely as a preliminary to the infantry attack; and it was not until the rude awakening of the early battles of the Boer war, that it was realized in England that unless the infantry co-operate, the artillery is not likely to produce any result. If the attacking infantry is kept at such a distance from the position that it cannot pass quickly to the assault, the enemy will retain his troops under cover during the cannonade, perhaps even leaving his trenches unoccupied, and present no target to the guns. Indeed, a most instructive instance of this very line of action is furnished by the battle of Ta-shih-chiao. There the right of the Russian line was held by the infantry of the 1st Siberian army corps, supported throughout the greater part of the day by only two batteries of artillery. So heavy was the fire of the Japanese artillery in this portion of the field that General Stakelberg, the commander of the Russian corps, sent word to his superior officer that he had not considered it advisable to occupy his trenches, and that should he be compelled to do so his troops must suffer very heavy loss. As things turned out the Japanese infantry did not deliver any attack against the Russian right, the defenders remained under cover, and the losses inflicted by the bombardment were almost negligible. Other instances might be quoted, but enough has been said to prove that to render the artillery bombardment effective the infantry must co-operate; for by this means only will the enemy be compelled to man his defences, to show himself above his parapets, and to expose himself to shrapnel fire.

Artillery action.

Here arises one of those questions which are the outcome of modern science, but which have not been finally answered by modern war. As a result of improved ballistics, better methods of observation, and perfected methods of communication, it is now possible for field artillery to make use of indirect fire from behind cover. Against stationary objects, such as a battery in action, the results achieved by this method are as good as those which are obtained by firing directly over the sights. At the same time the control of indirect fire is slow, and it still remains to be proved whether it can be used satisfactorily against quickly moving targets. If it should be found that, in spite of scientific aids, the artillery of the defence can be made to leave its cover and to disclose its position by the advance of the infantry, the importance of the aid which one arm can render to the other needs no demonstration. After all, however, the silencing of the guns of the defence is but a means to an end, and the principal aim of the guns of the attack is to enable the infantry to get sufficiently close to the position to deliver an assault; for the infantry assault is the crowning act of battle. Similarly the gunners of the defence must never forget that their great object is to repel this same assault. The artillery duel, therefore, is but a phase. Sooner or later one side will gain the upper hand. Then it must be decided whether the inferior artillery can best serve the interests of the infantry by continuing the duel, or by ceasing to fire until it can find some more vulnerable target.

Should the guns of the defence have proved inferior to those of the attack, it will probably be wise for them to wait until the advancing columns of infantry have deployed; should the positions be reversed, it will be well for the gunners of the attack to leave their weapons and to remain under cover until such time as their opponent is compelled to turn his attention to repelling the infantry. So great is the power of the modern rifle and quick-firing gun that infantry, unsupported by artillery, has but little chance of carrying a position held by determined men, and it is for this reason, and not with a view to saving their own lives, that the gunners must reserve themselves until the last moment. They must be ready and alert when their services are most required; moreover their final positions should be selected with a view to keeping up their fire until the last possible moment. Indeed they must often run the risk of injuring some of their own troops when firing over their heads. Sometimes a favourable position may be found for the artillery upon the flank of the attack. Such positions have a double advantage. Not only do they bring enfilade or oblique fire to bear upon the enemy's trenches, but they are able to continue the bombardment much longer than is possible when posted directly in rear of the assaulting columns. But whatever the position of the artillery may be, one thing is certain: namely, that the infantry of the attack can hardly hope to succeed if its own guns have been disabled while striving to maintain an unequal duel. Thus in the earlier stages of battle the action of the artillery will be characterized by a certain degree of prudence. The commanders on either side will strive to conceal the numbers and positions of their batteries, and will not employ more guns than are absolutely necessary for the attainment of any particular object they may have in hand. But when the preliminary stages are over, and the infantry is finally committed to the assault, a change must come over the conduct of the artillery. In this final phase there is no longer room for prudence. Indirect fire is out of place, and the duty of the guns cannot be better described than in the words of the French text-books, "to follow the infantry in a series of rapid advances, by échelons, without hesitating to come into action within the shortest range of the hostile infantry." But when the time comes to follow up the infantry the skill and knowledge of the battery commander are most highly tried. Concealment is no longer his object, and he must trust all to his offensive power. To make the most of this power it is of the first importance that his guns should be brought at once into positions whence they can be effectively used; for, quoting again from the French instructions, "considerations of concealment lose their importance for artillery that is told off to follow up the movements of the infantry. In this case artillery must not fear to come into action in the open, although in this situation a battery usually forfeits its freedom of manoeuvre."

Even the introduction of shielded guns will not affect this loss of mobility, for batteries which are brought to within effective rifle range of the defence must expect to lose a considerable proportion of their horses. Hence it follows that although the position into which they are brought in support of infantry may prove to be unsatisfactory it cannot be changed; their assistance will be lost at the most critical moment, with the result that the attack, deprived of their support, will probably fail. In France, where artillery tactics have perhaps received even more attention than in other countries, the necessity for this close support by guns has been so far recognized that the batteries of the attack have been divided into two distinct portions. The duties of one section have already been described. Those of the second are:—(1) To continue to shell the enemy's position as long as possible without danger to the advancing infantry; (2) To engage the hostile infantry "avec la dernière énergie"; (3) To watch carefully for counter-attack.

It is perfectly clear that the performance of these duties, in fact, the application of the whole principle of co-operation between infantry and artillery, is intimately connected with the use of ground. The art of utilizing ground to the best advantage must therefore be deeply studied. If we look back upon history, we cannot but be struck by the important part that the appreciation or neglect of the capacities of the ground has played in almost every battle. The most brilliant victories have been won by manoeuvres which, if not suggested by the physical features of the battlefield, were deprived by the nature of the ground of half their risk. What was true of Austerlitz and Leuthen is true of Liao-yang and Mukden. Now, as in the past, battles resolve themselves into a series of struggles for certain localities, a methodical progression from point to point, each successive capture weakening the enemy's position until at last an overwhelming fire can be brought to bear upon some vital point. This method of attack is most distinctly seen in siege operations, such as those round Port Arthur, where the attack closed gradually in upon the defence until the possession of one or two points rendered the capture of the place a matter of time alone. Now the difference between the attack of a fortress and of a defended position is, in the main, one of degree rather than of kind. But there is no doubt that the chief point of difference is often overlooked, both by the amateur and by the uneducated professional soldier.

In staff rides and in war games, occasionally even in peace manoeuvres, it is usually assumed that the party who starts upon the defensive must remain in that unenviable position throughout. This, however, is not the teaching of history. If there is one lesson in tactics which stands out more clearly than all the others which may be learnt from the campaigns of the great commanders, it is that a defensive attitude should never be assumed except as a means of passing to the offensive under more favourable conditions than those which present themselves at the moment. In siege operations the rôles of the rival forces are more clearly defined; and until the operations are brought to a conclusion the relations of the two commanders remain unchanged. In the open field of battle, except in the case of a purely delaying or of a rearguard action, this is not the case. There both generals, if they understand their duties, are always striving to secure the offensive, for no battle has ever yet been won by purely defensive tactics. The defensive attitude is, therefore, only a phase of that manoeuvring to secure the upper hand which begins with the strategic concentration, almost, one might say, with the peace organization.

Offensive-defensive.

In spite of Moltke's oft-quoted saying that the combination of the tactical defensive with the strategical offensive is the strongest form of war, the very fact of one side adopting the defensive proves, in at least ninety-nine cases out of every hundred, that in earlier stages of the campaign the enemy has gained an advantage, either by his numbers, his strategy, or his readiness to act, which can only be counterbalanced by success in battle. Other things being equal, the side which is numerically the weaker is naturally the first to be forced to relinquish the initiative. But, whatever the cause, the aim of the commander will be to retrieve his fortunes by a tactical success. Perhaps the most striking example in history of its accomplishment is furnished by the campaign and battle of Salamanca. There, after weeks of marching and counter-marching, Wellington was finally out-manoeuvred by Marmont and forced to stand and fight under circumstances by no means favourable to the defence. His line of communication was in danger, and his trains were already being hurried to the rear. Then Marmont made a mistake; and in a few hours the French army was in full retreat. Never was the tactical genius of a commander more dramatically displayed; but we may well ask ourselves whether under modern conditions similar results would be possible. The point is, however, that to the true general the purely defensive battle is unknown; and in place of a single movement directed by a master mind we shall see in future a series of combats, each with its stroke and counter-stroke, taking place upon a front extending over many miles of country. Of this type of battle the Sha-ho is at present the best example. There the operations opened with an attack against the Japanese right, which was met by a similar attack delivered by the Japanese centre and left. A less able commander than Oyama might have attempted to check Kuropatkin's offensive movement by reinforcing his own threatened flank; that is to say, that he would have conformed to the movements of his adversary and permitted him to dictate the course of events. This was not the Japanese system. Oyama had no intention of fighting a purely defensive action. He knew that his opponent had massed his strength upon his left, and it was only reasonable to assume that if one portion of his line was strong, some other portion must be weak. The actual point first selected by Oyama for decisive attack was the centre of Kuropatkin's line. This effort failed, and the scales were ultimately turned by an almost unexpected success against the Russian right. The resulting victory was certainly less complete than would have been the case had the Japanese commander been able to carry through his original plan, but it is obvious that a force operating against the centre of a hostile line must itself be in danger of envelopment; and in this case it is interesting to note that the battle was really decided by an outflanking movement by a weak force, while the central attack in considerable strength achieved but little. Oyama's conduct of this battle has been much criticized. By some writers he has been blamed for leaving his own defensive line too weak; by others he has been accused of attempting too much. These are difficult questions, requiring detailed examination; for the present it is sufficient to note that, although inferior in numbers, he succeeded in accomplishing an enveloping movement which forced his enemy to retire. The fact is that by superior skill, although actually inferior in numbers, he succeeded in placing more rifles in the firing line than did his opponent. During a great part of this struggle, which lasted for five days, it would be difficult to say which side was on the defensive and which on the offensive. No doubt at the commencement Kuropatkin was the assailant; it is equally certain that in the end it was Oyama who attacked; yet it would be impossible to say, as at Austerlitz and Salamanca, exactly at what moment the rôles were exchanged.

If then we are justified in assuming that in the great battles of the future neither army will be acting entirely on the offensive or entirely on the defensive, it may seem idle to speculate as to whether the recent improvements in firearms and ballistics are in favour of one side or the other. In this connexion the lessons which may be learned from the South African and the Russo-Japanese wars are most instructive. After the former it was often urged that the conditions of modern battle are distinctly in favour of defensive tactics; in other words, that the force which awaits attack can develop the full power of each arm with greater facility than that which delivers it. This contention had much to support it, but it was not always realized that anything which gives new strength to the defence must at the same time add something to the advantages of the army which attacks. The outcome of the improvements in rifles, guns and powder is that far fewer men are required to hold a definite position than of old. To a certain extent this favours the defence. A much larger proportion of the available troops can be set free to act in reserve, and to deliver the counter-stroke, *i.e.* a much larger number than formerly can be employed by the defenders in attack. This is to the good. But the assailant profits in almost equal ratio. His strength has always lain in power of manoeuvring, of hiding his movements, and of massing suddenly against some weak point. To-day this power is greater than ever before. The increased power of the rifle renders it comparatively easy for him to form an impenetrable barrier with part of his force, perhaps with his cavalry supported only by a small proportion of his infantry, behind which the remainder can move unobserved. Moreover, the object of the assailant's manoeuvres will be to place portions of his forces on the flank or flanks of the position he is attacking. If he can accomplish this, the effect, moral and physical, of the enfilade fire which is brought to bear upon the enemy's front will be far greater than that which attended a similar operation when fire was of less account. In addition to this increased facility for manoeuvre, the great strength of the local defensive confers upon the assailant the power of denuding certain portions of his line of troops, in order that he may mass them for offensive action elsewhere. Here again the study of ground and a true knowledge of the capabilities of the various arms are of supreme importance. Well-placed artillery, aided by machine guns, may enable a comparatively weak force of infantry to hold a wide extent of front, provided that each arm is able to use its strength to the fullest extent. In this way the skilful commander can turn each feature of the battlefield to account and can release a greater number of his troops for the all-important enveloping movements. It was just this power which enabled Oyama to outflank the Russian XVII. Corps at the battle of Sha-ho, for he was able to weaken his own right to an extent which a very few years ago would have been impossible. In short, the process of envelopment is more easy than it used to be; and envelopment, which means that the enemy is under fire from several directions, is much more effective now than in the past.

In Germany this fact has long been recognized, and it was for this reason that German soldiers refused to accept the conclusions at which many English military critics arrived after the South African war. Under the influence of their German teachers the Japanese never hesitated to attack, even with inferior numbers, and to make the envelopment of the enemy more certain they went into battle practically without reserves.

In this respect the war in Manchuria marks an epoch in the history of tactics; and for that reason, if for no other, it should be carefully studied. Moreover, it emphasizes an important difference in the handling of large and small armies which is of quite recent origin. Until a few years ago all continental armies were organized in army corps. These corps were composed of two or three infantry divisions with a large body of corps troops, principally artillery. Now the *raison d'être* of this artillery was to form the nucleus of a reserve which could be retained under the hand of the corps commander to be used as required. That is to drive home the infantry attack, to deliver or repel a counter-attack, or, but very sparingly, to strengthen a weak point in the defensive line. With the development of the enveloping battle, it was soon realized in Germany that corps artillery was an anachronism, for the distances are now so great that reserve artillery can hardly be moved to the particular part of the battlefield where its services are required in time to be of any use. Thus the corps artillery was first split up among the divisions, and soon a number of divisional reserves took the place of the great central body, while the corps commander retained a comparatively small number of troops under his own hand. In this way the control of the supreme commander over the course of the battle is greatly weakened and the chance of correcting any error in the original plan is diminished. It had long been realized that errors in the strategic deployment of troops were almost impossible to correct; and now it came to be seen that this was equally true of the tactical deployment. Just as under modern conditions even Napoleon could hardly have recovered from errors like those which marked the opening phases of the Eckmühl campaign (see NAPOLEONIC CAMPAIGNS), so the most brilliant genius will no longer be sufficient to win battles if the original plan is not correct. It was upon this theory that the Japanese commanders planned their battles, and it was very soon proved that they had the courage of their convictions. For the first time it was seen that battles were no longer won by the general who husbanded his reserves, but by him who first got every available man into the firing line. But, while giving Oyama, Kuroki, Oku and the others every credit for the strength of mind which enabled them to divest themselves of reserves when their battles were far from being won, we must also remember that they were fighting an enemy who, like the Boers, were incapable of organizing a really decisive counter-stroke. For English soldiers this point has a peculiar interest, as it has a very distinct bearing upon the tactics of our own army. From what has already been said it is, or should be, clear that the value of numbers upon the battlefield is greater now than formerly; for, granting that the leadership on either side is equally skilful, the chances of envelopment are in favour of him who commands the greater number of men. Owing

Corps and divisional artillery.

to our geographical position and to the conditions under which we live, the number of British troops available for employment in any war against a continental Power will almost certainly be inferior to that which can be employed against us. It is of course true that we should never engage in operations on the continent of Europe except in alliance with some other Power; but it is quite possible that the British army might be entrusted with the execution of some definite task which, while part of a general strategical scheme, would involve completely independent action. It is under such circumstances as these that we must be prepared to encounter troops which in leadership and training will be at least the equal of our own, and in numbers will probably be superior to them. In these circumstances our chances of envelopment will not be great, but this must by no means be taken to mean that our chances of success are to be despaired of. Far from it. In the first place strategy may induce the enemy temporarily to divide his forces, and thus to afford favourable opportunity for an effective blow. Failing this, it remains to be considered how a general may best employ inferior numbers with a reasonable hope of gaining a tactical victory. To this the answer must be that his best, indeed his only, chance of victory lies in the counter-stroke.

In France this fact has received due recognition, and since that country is in the unfortunate position of having to be prepared to encounter superior numbers, the training and organization of her armies differ essentially from those of her most formidable neighbour. Acknowledging that at the outset of a war she must be placed at a grave disadvantage, she strives to develop her power of manoeuvre and of delivering a strategic counter-stroke. With this object her armies move in deep formations on a comparatively narrow front, covered by strong advanced guards. Thus, in the earlier stages, they are much less committed to a definite line of action than are armies moving upon a widely extended front, and, provided intelligence is received in time, they can be massed quickly against the enemy's flanks. Similarly in the later stages she trusts to the tactical counter-stroke, and hence the corps artillery, which has been abandoned in Germany for reasons which have already been given, is still retained in France.

The counter-stroke.

In the foregoing pages the question was raised as to whether the great tactical counter-strokes of the past are still possible under modern conditions. Unfortunately the battles in Manchuria afford no instance of a successful counter-stroke, for the Sha-ho is more an example of an encounter action than of a carefully conceived counter-attack. In these circumstances we are forced to rely upon theory; but theory based upon a correct understanding of the past should form no uncertain guide to the practice of the future. What then are the principles upon which our theory is to be based? First, that the defensive battle is only a step towards assuming the offensive. Secondly, that the only means of assuming the offensive with success is the counter-stroke. Thirdly, that the counter-stroke, in at least nine cases out of every ten, should aim at the envelopment of the attack. From these premises it follows that the most effective form of the defensive battle will be that which compels the enemy to deploy his forces and then uses the reserve to envelop one or both of his flanks. Since, however, modern battles are fought over a very wide extent of front, it necessarily follows that the possibility which the defence possesses of successfully enveloping the attack must depend to a very great extent upon the correct disposal of the reserves when drawing up the original line of battle. Just as the chances of making the best use of superior number in the attack depend upon a correct strategical deployment at the commencement of a campaign, so the chances of a successful counter-stroke depend upon a correct distribution of troops at the commencement of an action. Hence we see that the most important point which a general who finds himself compelled to take up a defensive position has to decide is where to place those troops by whose aid he hopes eventually to seize the offensive. One thing is clear, namely, that the worst place for men who are destined to envelop one or other flank of the attack must be behind the centre of the defensive line. Time alone must render such a position unsuitable, for it must entail a march of many hours, if not of days, before the troops can reach the point from which they are to be launched to the attack. This being so, it would seem that the right place for the general reserve of the defending army under modern conditions must be on one or other of the flanks; and, always bearing in mind that the chief object to be attained is regaining the initiative, we are driven to the conclusion that the best place is that flank from which an effective blow can be dealt at the assailant's most vulnerable point, that is to say, at the flank through which his line of communication may be most easily attained. If this theory be correct, yet another point has been established, namely, that the main plan of the decisive counter-stroke must be decided before, and not after, the first shot in the general engagement has been fired. Under the conditions which obtain to-day it is no use waiting for the enemy to make a mistake, for the odds against it being detected are great. A hundred years ago armies manoeuvred in full view of one another, and mistakes could be perceived by every company officer on either side. Now all this is changed, and the difficulties of the defence are increased by the fact that although the attack may make many blunders, it will do so at such a distance from the defence as to render them comparatively secure from detection. Having prepared his counter-stroke, the chief point towards which the commander of the defence must direct his attention after battle has been joined, is the exact moment at which it should be delivered. Needless to say that the chances of success will be enormously increased if the counter-stroke is unexpected, for in war the demands which surprise makes upon moral are quite out of proportion with the physical danger which men are called upon to undergo. If then defence is ever to be converted into attack, it would appear: (1) That the counter-stroke must be carefully planned, and must form an integral part of the *original* scheme of defence. (2) That it must be properly directed. (3) That it must be correctly timed. (4) That if possible it must come as a surprise. Of these conditions, the first three are dependent for their fulfilment upon good information, careful preparation, and correct appreciation of the enemy's plans; but it is in the fourth that the inspiration of the really great commander will be most conspicuously displayed on the day of battle, and the greater the numbers under his command the more difficult his task must be.

When, as at the Sha-ho and Mukden, the troops on either side are numbered by hundreds of thousands, the commander-in-chief cannot hope to keep the direction of events in his own hands for very long; but when tens of thousands only are engaged, the whole battle can be controlled as well now as in the past. The extent of front will certainly be greater than it was formerly, but against this may be set the fact that improved communications by telegraph and telephone enable the commander to keep in touch with events in a manner which until recently was quite impossible. It is for this reason that the earlier and smaller battles of the Russo-Japanese War contain many lessons which are of more use to British soldiers than are those which may be learned from the great struggles which took place later on. But in all battles, whether great or small, the first requirement is a commander who possesses sufficient steadfastness of character to carry out on the day of battle the plans he has formed beforehand. War is like a game of bridge, for the most successful player is not he who best remembers the fall of the cards or who knows the correct leads by heart, but he who can decide upon and carry out the plan best suited to the strength of his hand. In both cases a bad plan is better than none, and vacillation even between two good plans is fatal. In both cases side issues are constantly arising which tend to obscure the main issue. On the battlefield these side issues take the form of appeals for assistance from various quarters, all of which must tempt the supreme commander to weaken the general reserve which has been set aside for his decisive stroke. To such appeals he must turn

Economy of force.

a deaf ear, confident in the knowledge that the best way of assisting his sorely-pressed troops is by a vigorous blow at his enemy's weakest spot. Hence it follows that the force which is to deliver the blow must be kept perfectly distinct from the local reserves under subordinate commanders, which are held in readiness to strengthen weak places in the defensive line, or to deliver local counter-attacks. It also follows that this force must comprise every man who can be spared from the passive portion of the defence, and that to produce the fullest results there must be complete co-operation between the three arms.

It is here, in all probability, that cavalry will find its opportunity. On the one hand, the cavalry of the attack will strive to locate the hostile reserve which is preparing to deliver a counter-attack; failing this it will protect the flanks of its own infantry, ready to move to any threatened point and to assist with dismounted fire in repelling the advancing lines when the necessity arises. On the other hand, the cavalry of the defence will strive to conceal the movements of its own general reserve and will locate the flanks of the infantry against which the counter-attack is to be directed. The share of the artillery in this stage of the battle is sufficiently apparent, and it is obvious that the chances of success of one side or the other must depend largely upon the skill and self-sacrifice of the gunners. Should the commander of the defence, aided by his cavalry, have been successful in effecting a surprise, his chances of victory will be further increased if his infantry is supported closely by the artillery. Much also must depend upon the handling of the artillery which has suddenly been thrown upon the defensive. If the battery leaders are quick to realize the changed situation and to pick up new targets, perhaps leaving covered positions and firing over the sights, all may yet be well; but it is certain that if the surprise has really been complete the infantry will require all the assistance it can possibly derive from the other arms in order to avert defeat.

One more point remains to be noted. Since the object of tactics is to win battles, every effort should be directed to that single end. If certain formations are adopted with a view to avoiding losses, it must only be in order that more men may be brought up to the decisive point. The same principle holds good with regard to what are known as holding, or secondary, attacks whose rôle is frequently misunderstood. Indeed the names themselves are misleading, for they inevitably convey the impression that the duty of winning has been entrusted to some other body. For this reason the commander is apt to consider that he has fulfilled his task if he succeeds in getting to within reasonably close range of the enemy's position, where he can remain without suffering undue loss. Far from this being the case, the fact is that against an able opponent an attack of this nature is useless, for he will very soon detect which is the real and which is the secondary attack, and unless the two are pushed with equal vigour he will disregard the one and turn all his attention to the other. It may even happen that he will be able to take troops from that portion of his line which is only threatened and place them where he is really pressed, or even utilize them in counter-attack. In such a case it may happen that the so-called "holding" attack may itself be held by less than its own numbers, while the main attack is suffering defeat in some other quarter of the field. Here again there is much to be learnt from the past; and for the true conduct of these feint attacks we need not go outside the history of our own army. Many instances might be quoted, but none are more to the point than that of the assaulting columns at the capture of Badajoz. On that memorable occasion the British troops were divided into five columns, three of which were vainly hurled against the great breaches which had been made in the walls. But what the main assaults failed to do was accomplished by the attacks from which least had been expected; and Philippon with his gallant defenders was forced to surrender by the loss of the San Vincente bastion and the castle of San Roque, which had been considered to be impregnable. This is the spirit which must imbue the infantryman, the cavalryman, and the artilleryman alike. For without the fighting spirit, neither generalship, formations, nor weapons can prevail. (N. M.*)

Holding attacks.

TADPOLE, a term often, but wrongly, applied indiscriminately to all Batrachian larvae. It is absurd to call the larva of a newt or of a Caecilian a tadpole, nor is the free-swimming embryo of a frog as it leaves the egg a tadpole. A tadpole is the larva of a tailless Batrachian after the loss of the external gills and before the egress of the fore limbs (except in the aberrant *Xenopus*) and the resorption of the tail. What characterizes a tadpole is the conjoined globular head and body, so formed that it is practically impossible to discern the limit between the two, sharply set off from the more or less elongate compressed tail which is the organ of propulsion. In describing tadpoles, the term "body" is therefore used as meaning head and body. The tail consists of a fleshy muscular portion bordered above and below by membranous expansions, termed respectively the upper and lower crest, the former sometimes extending along the body.

Except in a few aberrant types, which are mentioned below, the mouth is surrounded by a much developed lip like a funnel directed downwards, and is armed with a horny beak not unlike that of a cuttle-fish. The characters offered by the circular lip are among the most important for the distinction of species. It may be entirely bordered by fleshy papillae, or these may be restricted to the sides, or to the sides and the lower border. Its inner surface is furnished with ridges beset with series of minute, bristle-like, erect, horny teeth, each of which, when strongly magnified, is seen to be formed of a column of superposed cones, hollowed out at the base and capping each other; the summit or crown of each of these cones is expanded, spatulate, hooked backwards, and often multicuspid. The number of these columns is very great. F. E. Schulze has counted as many as 1100 in the lip of *Pelobates fuscus*. The beak is made up of horny elements, like the labial teeth, fused together; its edge, when sufficiently magnified, is seen to be denticulate, each denticle representing the cusp of a single tooth. The gills, borne on four arches, are internal and enclosed in the branchial chambers. The arches bear on the convex outer side the delicate arborescent gills, and on the concave inner side develop a membranous septum with vermicular perforations, a special sifting or filtering contrivance through which the water absorbed by the mouth has to pass before reaching the respiratory organs of the branchial apparatus.

The water is expelled from the branchial chambers by one or two tubes opening by one orifice in most Batrachians. This orifice is the spiraculum, which is lateral, on the left side of the body, in most tadpoles, but median, on the breast or belly, in those of the *Discoglossidae* and of some of the *Engystomatidae*. All tadpoles are provided with more or less distinct lines of muciferous sensory crypts or canals, which stand in immediate relation to the nerve branches and are regarded as organs of a special sense possessed by aquatic vertebrates, feeling, in its broadest sense, having been admitted as their possible use, and the function of determining waves of vibration in the aqueous medium having been suggested. In addition to these lines, all tadpoles show more or less distinctly a small whitish gland in the middle of the head between the eyes, the so-called frontal gland or pineal gland, which in early stages is connected with the brain. A glandular streak extending from the nostril towards the eye is the lachrymal canal. The eyes are devoid of lids.

Owing to more or less herbivorous habits, the intestine is exceedingly elongate and much convoluted, being several times larger and of a greater calibre than after the metamorphosis. Its opening, the vent, is situated either on the middle line at the base of the tail, or on the right side, as if to balance the sinistral position of the spiraculum. The tail varies much in length and shape according to the species; sometimes it is rounded at the end, sometimes more or less acutely pointed, or even terminating in a filament. The skeleton is cartilaginous, and the skull is remarkable for the very elongate suspensorium of the lower jaw; the tail remains in the notochordal condition, no cartilages being formed in this organ, which is destined to disappear with the gills. The hind limbs appear as buds at the base of the tail, and gradually attain their full development during the tadpole life. The fore limbs grow simultaneously, and even more rapidly, but remain concealed within a diverticulum of the branchial chambers until fully formed, when they burst through the skin (unless the left spiraculum be utilized for the egress of the corresponding limb).

The above description applies to all European and North American tadpoles, and to the great majority of those known from the tropics. The following types are exceptional.

The circular lip is extremely developed in *Megalophrys montana*, and its funnel-shaped expansion, beset on the inner side with radiating series of horny teeth, acts as a surface-float, when the tadpole rests in a vertical position; the moment the tadpole sinks in the water the funnel collapses, taking on the form of a pair of horns, curling backwards along the side of the head; but, as they touch the surface again, it re-expands into a regular parachute.

In some species of *Rana* and *Staurois* inhabiting mountainous districts in south-eastern Asia, the larvae are adapted for life in torrents, being provided with a circular adhesive disk on the ventral surface behind the mouth, by means of which they are able to anchor themselves to stones.

In some Indian and Malay Engystomatids of the genera *Callula* and *Microhyla*, the tadpoles are remarkably transparent, and differ markedly in the structure of the buccal apparatus. There is no funnel-shaped lip, no horny teeth, and no beak. The spiraculum is median and opens far back, in front of the vent.

In the Aglossal *Xenopus*, the tadpoles are likewise devoid of circular lip, horny teeth, and beak, and they are further remarkable in the following respects: There is a long tentacle or barbel on each side of the mouth, which appears to represent the " balancer " of Urodele larvae; the spiraculum is paired, one on each side; the fore limbs develop externally, like the hind limbs.

Some tadpoles reach a very great size. The largest, that of *Pseudis paradoxa*, may measure a foot, the body being as large as a turkey's egg. The perfect frog, after transformation, is smaller than the larva. *Pseudis* was first described by Marie Sibylle de Mérian (1647–1717), in her work on the fauna of Surinam (published first in 1705 at Amsterdam, republished in Latin in 1719), as a frog changing into a fish. Among European forms, some tadpoles of *Pelobates* attain a length of seven inches, the body being of the size of a hen's egg. The tadpole of the North American bull-frog measures six inches, and that of the Chilian *Calyptocephalus gayi* seven and a half inches.

TAEL (Malay *tail*, *tahil*, weight, probably connected with Hind. *tola*, weight), the name current in European usage for the Chinese *liang* or ounce, the *liang* of fine uncoined silver being the monetary unit throughout the Chinese empire. The *tael* is not a coin, the only silver currency, apart from imported dollars, being the ingots of silver known as " sycee "; the only other native currency is the copper " cash." As a money of account the *tael* is divided into 10 *mace* (*tsien*), 100 *conderin* or *candereen* (*fun*), 1000 *li*. The value varies with the price of silver. The " Haikwan tael," *i.e.* the custom-house tael, that in which duties are paid to the Imperial Maritime Customs, is a weight of 58–77 grains Troy, the value of which varies; thus it was reckoned at 3s. $1\frac{1}{10}$d. in 1905, 3s. $3\frac{1}{2}$d. in 1906, 3s. 3d. in 1907, and 2s. 8d. in 1908 (see China: § *Finance*).

TAENIA (Gr. ταινία, ribbon, fillet), the term in architecture given to the projecting fillet which crowns the architrave of the Greek Doric order.

TAFILÁLT, or Tafilet (*i.e.* " The Country of the Filáli," as its inhabitants are called, because descended from the Arabian tribe of Hilál, settled here in the 11th century), the most important oasis of the Moroccan Sahara, ten days' journey south of Fez, across the Atlas. It is celebrated for its large and luscious dates, to the successful cultivation of which, soon after the arrival of an ancestor of the reigning dynasty of Morocco (hence called the Filáli Sharifs, *i.e.* descendants of Mahomet) *circ.* A.D. 1250, this dynasty owes its rise to power. Since 1648 it has been the custom of Moorish sultans to despatch superfluous sons and daughters to Tafilált, and as the males are all sharifs, the fanaticism against Europeans is comprehensible. Instead of living in towns its bellicose inhabitants occupy isolated fortified buildings, and are constantly at war. In Ifli, the central portion, formerly existed the town of Sagilmasa, founded by Miknása Berbers in 757 B.C. It was on the direct caravan route from the Niger to Tangier, and attained a considerable degree of prosperity. It was destroyed at the end of the 11th century, but its ruins still extend five miles along the river bank.

The first European to visit Tafilált was Rene Caillie (1828), the next Gerhard Rohlfs (1864). A later visit to the oasis by W. B. Harris is described in his book *Tafilet* (London, 1895).

TAFT, LORADO (1860–), American sculptor, was born at Elmwood, Illinois, on the 29th of April 1860. He graduated from the University of Illinois in 1879, and from 1880 to 1883 studied in the École des Beaux Arts, Paris. In 1886 he became instructor at the Art Institute, Chicago, lecturing there, at the Chicago University, and elsewhere in the United States. He is the author of an exhaustive and authoritative work, *The History of American Sculpture* (1903). Among his works, in addition to much portraiture, are: " Sleep of the Flowers " and " Awakening of the Flowers," both made for the Columbian Exposition; " Despair " (1898); " Solitude of the Soul " (1900), and " Fountain of the Lakes " (1903).

TAFT, WILLIAM HOWARD (1857–), the twenty-seventh President of the United States, was born in Cincinnati, Ohio, on the 15th of September 1857. His father, Alphonso Taft (1810–1891), born in Townshend, Vermont, graduated at Yale College in 1833, became a tutor there, studied law at the Yale Law School, was admitted to the Connecticut bar in 1838, removed to Cincinnati in 1839, and became one of the most influential citizens of Ohio. He served as judge of the Superior Court (1865–72), as secretary of war (1876) and as attorney-general of the United States (1876–77) in President Grant's cabinet; and as minister to Austria-Hungary (1882–84) and to Russia (1884–85).

William Howard Taft attended the public schools of Cincinnati, graduated at the Woodward High School of that city in 1874, and in the autumn entered Yale College, where he took high rank as a student and was prominent in athletics and in the social life of the institution. He graduated second (salutatorian) in his class in 1878, and began to study law in Cincinnati College, where he graduated in 1880, dividing the first prize for scholarship. He was admitted to the Ohio bar in 1880. For a few months he worked as a legal reporter for the Cincinnati *Times* (owned by his brother C. P. Taft), and then for the Cincinnati *Commercial*. Early in 1881 he was appointed assistant prosecuting attorney of Hamilton county (in which Cincinnati is situated), but resigned in 1882 on being appointed collector of internal revenue of the United States for the first district of Ohio. The work was distasteful, however, and in 1883 he resigned to return to the law. From 1885 to 1887 he served as assistant solicitor of Hamilton county, and in the latter year was appointed judge of the Superior Court of Ohio to fill a vacancy. He was elected by the people in the next year and served until 1890, when he was appointed solicitor-general of the United States by President Benjamin Harrison. His work in connexion with the drafting of the Sherman Anti-Trust Act and with the Bering Sea controversy attracted attention. In 1892 he was appointed a judge of the Sixth Circuit, United States Court, and became known as a fearless administrator of the law. Several decisions were particularly objectionable to organized labour. The first of these, decided in 1890, upheld the verdict of a jury awarding damages to the Moores Lime Company, which had sustained a secondary boycott because it had sold material to a contractor who had been boycotted by Bricklayers' Union No. 1. The second decision grew out of the attempt of the Brotherhood of Locomotive Engineers to prevent other roads from accepting freight from the Toledo, Ann Arbor & North Michigan railroad, against which a "legal" strike had been declared. Judge Taft granted an injunction (7th March 1893) against the Pennsylvania railroad, making P. M. Arthur, chief of the Brotherhood, a party, and called Rule 12, forbidding engineers to haul the freight, criminal. During the great railway strikes of 1894 Eugene V. Debs, president of the American Railway Union, sent one Frank W. Phelan to tie up traffic in and around Cincinnati. The receiver of the Cincinnati, New Orleans & Texas Pacific railway applied for an injunction against Phelan and others, which was granted. Phelan disobeyed the injunction and on the 13th of July 1894 was sentenced to jail for six months for contempt. The doctrine that "the starvation of a nation cannot be the lawful purpose of a combination" was announced, and Judge Taft said further that "if there is any power in the army of the United States to run those trains, the trains will be run." In 1896–1900 Judge Taft was professor and dean of the law department of the University of Cincinnati.

A movement to elect Mr Taft president of Yale University gained some strength in 1898–99, but was promptly checked by him, on the ground that the head of a great university should be primarily an educationalist. In 1900 he was asked by President McKinley to accept the presidency of the Philippine Commission charged with the administration of the islands. Though he had been opposed to the acquisition of the Philippines, he did not believe that the inhabitants were capable of self-government, and he foresaw some of the difficulties of the position. Yielding, however, to the urgent request of the president and his cabinet, he accepted and served from the 13th of March 1900 to the 1st of February 1904. On the establishment of civil government in the islands, on the 4th of July 1901, he became governor, *ex officio*. The task of constructing a system of government from the bottom, of reconciling the conflicting and often jealously sensitive elements, called for tact, firmness, industry and deep insight into human nature, all of which Governor Taft displayed in a marked degree. (See PHILIPPINE ISLANDS.) The religious orders had been driven out during the insurrection, but held title to large tracts of land which many Filipinos and some Americans wished to confiscate. This delicate matter was arranged by Mr Taft in a personal interview with Pope Leo XIII. in the summer of 1902. The pope sent a special delegate to appraise the lands, and the sum of $7,239,000 was paid in December 1903. Mr Taft gained great influence among the more conservative Filipinos, and their entreaties to him to remain influenced him to decline the offer of a place upon the Supreme bench offered by President Roosevelt in 1902.

Finally, feeling that his work was accomplished, Mr. Taft returned to the United States to become secretary of war from the 1st of February 1904. With a party of congressmen he visited the Philippines on a tour of inspection July-September 1905, and in September 1906, on the downfall of the Cuban republic and the intervention of America, he took temporary charge of affairs in that island (September–October). In the next year (March–April) he inspected the Panama Canal and also visited Cuba and Porto Rico. He again visited the Philippines to open the first legislative assembly (16th October 1907), and returned by way of the Trans-Siberian railway. On this tour he visited Japan, and on the 2nd of October, at Tokyo, made a speech which had an important effect in quieting the apprehensions of the Japanese on the score of the treatment of their people on the Pacific coast.

With the approach of the presidential election of 1908, President Roosevelt reiterated his pledge not to accept another nomination, and threw his immense influence in favour of Mr Taft. At the Republican convention held in Chicago, in June, Mr Taft was nominated on the first ballot, receiving 702 out of 980 votes cast. James S. Sherman of New York was nominated for Vice-President. During the campaign many prominent labour leaders opposed the election of Mr Taft, on the ground that his decisions while on the bench had been unfriendly to organized labour. In the campaign Mr Taft boldly defended his course from the platform, and apparently lost few votes on account of this opposition. At the ensuing election in November, Taft and Sherman received 321 electoral votes against 162 cast for William Jennings Bryan and John W. Kern, the Democratic candidates.

In his inaugural address (4th March 1909) President Taft announced himself as favouring the maintenance and enforcement of the reforms initiated by President Roosevelt (including a strict enforcement of the Sherman Anti-Trust Act, an effective measure for railway rate regulation, and the policy of conservation of natural resources); the revision of the tariff on the basis of affording protection to American manufactures equal to the difference between home and foreign cost of production; a graduated inheritance tax; a strong navy as the best guarantee of peace; postal savings banks; free trade with the Philippine Islands; and mail subsidies for American ships. He also announced his hope to bring about a better understanding between the North and the South, and to aid in the solution of the negro problem. In accordance with his pre-election pledge, Congress was called to meet in extra session on the 15th of March to revise the tariff. Hearings had been previously held by the Ways and Means Committee of the House of Representatives, and a measure was promptly reported. After passing the House it was sent to the Senate, where it was much changed. The final Payne-Aldrich Act was approved by the President on the 5th of August 1909, though in many respects it was not the measure he desired. The wish to meet people of the different sections of the country and to explain his position upon the questions of the day led the President to begin (14th September 1909), a tour which included the Pacific coast, the South-west, the Mississippi Valley and the South Atlantic states, and during which he travelled 13,000 miles and made 266 speeches.

Mr Taft delivered the Dodge lectures at Yale University in 1906 on the Responsibilities of Citizenship, published as *Four Aspects of Civic Duty* (1906). Some of his political speeches have been published under the titles *Present Day Problems* (1908), and *Politicial Issues and Outlooks* (1909).

TAGANROG, a seaport of southern Russia, on the N. shore of the Sea of Azov, in the Don Cossacks territory, some 170 m. S.E. of the town of Ekaterinoslav. It is built principally of wood, stands on a low cape, and has the aspect of an important commercial city. The imperial palace, where Alexander I. died in 1825, and the Greek monastery (under the patriarch of Jerusalem) are worthy of notice. Statues of Alexander I. (1830) and Peter the Great (1903) adorn the town. In the 13th century Pisan merchants founded there a colony, *Portus Pisanus*, which, however, soon disappeared during the migrations of the Mongols and Turks. An attempt to obtain possession of the promontory was made by Peter the Great, but it was not definitely annexed by the Russians until seventy years afterwards (1769). The commercial importance of the town dates from the second half of the 19th century; in 1870 its population had risen to 38,000, and after it was brought into railway connexion with Kharkov and Voronezh, and thus with the fertile provinces of south and south-east Russia, the increase was still more rapid, the number reaching 56,047 in 1885, and 58,928 in 1900—Greeks, Jews, Armenians and West-Europeans being important elements. The town was bombarded and in part destroyed by an Anglo-French fleet in May 1855. Taganrog is an episcopal see of the Orthodox Greek Church, and has tanneries, tallow works and tobacco manufactures. The roadstead is very shallow, and exposed to winds which cause great variations in the height of the water; it is, moreover, rapidly silting up. At the quay the depth of water is only 8 to 9 feet, and large ships have to lie 5 to 13 miles from the town. Moreover, the port is closed by ice three to four months in the year. Notwithstanding the disadvantages of its open roadstead, the foreign trade has rapidly expanded, the annual value of the exports having increased from 6½ millions sterling in 1899 to over 10 millions sterling in 1904. The chief article of export being corn, the trade of the city is subject to great fluctuations. Linseed and other oil-bearing grains are also important articles of commerce, as well as wool and butter. The imports, which consist chiefly of machinery, fruits (dried and fresh), wine, oil and textiles, do not much exceed half a million sterling annually.

TAGES (*Tăgēs*), a minor Etruscan deity, grandson of Jupiter, and founder of the art of divination in Etruria. According to the story, during the ploughing of a field near Tarquinii a being of boyish appearance sprang out of the furrow. The shouts of the ploughman (Tarchon) brought to the spot all the people of Etruria, whom the boy proceeded to instruct in the art of divination. Having done this, he suddenly disappeared. His instructions were for some time handed down orally, but were subsequently committed to writing, and formed the twelve books of Tages, containing a complete system of Etruscan lore.

See Cicero, *De Div.* ii. 23; Ovid, *Metam.* xv. 553; Festus, *s.v.*; Mommsen, *Hist. of Rome* (Eng. tr.), bk. i. ch. 12.

TAGLIACOZZI, GASPARO (1546–1599), Italian surgeon, was born at Bologna in 1546, and studied at that university under Cardan, taking his degree in philosophy and medicine at the age of twenty-four. He was appointed professor of surgery and afterwards of anatomy, and achieved notoriety at least, and the fame of a wonder-worker. He died at Bologna on the 7th of November 1599.

His principal work is entitled *De Curtorum Chirurgia per Insitionem Libri Duo* (Venice, 1597, fol.,; it was reprinted in the following year under the title of *Chirurgia Nova de Narium, Aurium, Labiorumque Defectu per Insitionem Cutis ex Humero, arte hactenus omnibus ignota, sarciendo* (Frankfort, 1598, 8vo).

TAGLIACOZZO, a town of the Abruzzi, Italy, in the province of Aquila, 56 m. by rail E.N.E. of Rome, and 10 m. W. of Avezzano. Pop. (1901) 4517 (town); 9061 (commune). It lies 2428 ft. above sea-level, at the mouth of the deep ravine of the Imele. It contains several old churches, notably S. Francesco, with a fine rose window in the façade, and medieval houses. The palace, built at the end of the 14th century by the Orsini, is fine. The place was given to the Colonna family in 1526. At the end of 1268 a battle took place here between Conradin of Hohenstaufen and Charles of Anjou, which resulted in the defeat of Conradin and his execution.

TAGLIONI, MARIA (1804–1884), Italian ballet dancer, daughter of Filippo Taglioni (1777–1871), master of the ballet at Stockholm, Cassel, Vienna and Warsaw, was born at Stockholm on the 23rd of April 1804. She was trained by her father, who is said to have been pitilessly severe. It was to his care and her own special talent for dancing that she owed her success, for she possessed no remarkable personal attraction. Her first appearance was at Vienna on the 10th of June 1822, in a ballet of which her father was the author, *La Réception d'une jeune nymphe à la cour de Terpsichore*. Her success was immediate, and was repeated in the chief towns of Germany. On the 23rd of July 1827 she made her Paris début at the Opéra, in the *Ballet de Sicilien*, and aroused a furore of enthusiasm. Among her more remarkable performances were the dancing of the Tyrolienne in *Guillaume Tell*, of the *pas de fascination* in Meyerbeer's *Robert le Diable*, and in *La Fille du Danube*. At this period the ballet was an important feature in opera, but with her retirement in 1847 the era of grand ballets may be said to have closed. In 1832 she married Comte Gilbert de Voisins, by whom she had two children. Losing her savings in speculation, she afterwards supported herself in London as a teacher of deportment, especially in connexion with the ceremony of presentation at court. During the last two years of her life she lived with her son at Marseilles, where she died on the 23rd of April 1884. Taglioni is frequently mentioned in the novels of Balzac; and Thackeray, in *The Newcomes*, says that the young men of that epoch "will never see anything so graceful as Taglioni in *La Sylphide*."

TAGUS (Span. *Tajo*, Portug. *Tejo*), the longest river of the Iberian Peninsula. Its length is 565 m., of which 192 are on or within the frontier of Portugal, and the area of its basin is about 31,850 sq. m. The basin is comparatively narrow, and the Tagus, like the other rivers of the Iberian tableland, generally flows in a rather confined valley, often at the bottom of a rocky gorge below the general level of the adjacent country. The river rises on the western slope of the Muela de San Juan (5225 ft.), a mountain which forms part of the Sierra de Albarracin, 88 m. E. of Madrid. Thence the Tagus flows at first north-westwards, but, after receiving the Gallo on the right, it flows west, and then south-west or west-south-west, which is its general direction for the rest of its course. Regular river navigation begins only at Abrantes, a few miles below which the Tagus is greatly widened by receiving on its right bank the impetuous Zezere from the Serra da Estrella. Passing Santarem, the highest point to which the tide ascends, and the limit of navigation for large sailing vessels and steamers, the river divides below Salvaterra into two arms, called the Tejo Novo (the only one practicable for ships) and the Mar de Pedro. These branches enclose a deltaic formation, a low tract of marshy alluvium known as the Lezirias, traversed by several minor channels. Both branches terminate in a broad tidal lake immediately above Lisbon (*q.v.*). The Tagus estuary, though partly blocked by a bar of sand, is one of the chief harbours of south-western Europe.

The narrower part of the Tagus basin lies to the south, and the left-hand tributaries which drain it are almost all mere brooks, dry in summer. The principal exception is the Zatas or Sorraia, which, rising in the Serra d'Ossa, flows westwards across the plateau of Alemtejo, and joins the Mar de Pedro. The principal right-hand tributaries, besides the Gallo and Zezere, are the Jarama, descending from the tableland of New Castile a little below Aranjuez, the Alberche and the Tietar, which collect their head waters from opposite sides of the Sierra de Gredos, and the Alagon, from the rough and broken country between the Sierras de Gredos and Gata.

TAHITI, the largest and most important of the French Society Islands (*q.v.*) in the Pacific Ocean, in 17° 38′ S., 149° 30′ W. Pop. about 10,300. The island, in shape not unlike the figure 8, has a length of 33 m., a coast-line of 120, and an area of 402 sq. m. It is divided into two portions by a short isthmus (Isthmus of Taravao) about a mile in width, and nowhere more than 50 ft. above sea-level. The southern, the peninsula of Taiarapu, or Tahiti-iti (Little Tahiti) measures 11 m. in length by 6 m. in breadth; while the northern, the circular main island of Porionuu, or Tahiti-uni (Great Tahiti), has a length of 22 m. and a breadth of 20. The whole island is mountainous. A little to the north-west of the centre of Great Tahiti the double-peaked Orohena rises to 7349 ft., and the neighbouring Aorai is only a little lower. Little Tahiti has no such elevation, but its tower-like peaks are very striking. The flat land of the Tahitian coast, extending to a width of several miles—with its chain of villages, its fertile gardens, and its belt of palms, sometimes intersected by stream-fed valleys which open on the seashore—forms a most pleasing foreground to the grand mountain ranges. A good road surrounds the island, the extreme north of which is formed by Point Venus, W. of which lie the Bay of Matavai and Papeete, the European town and seat of government, on its beautiful harbour.

Climate.—The seasons are not well defined. Damp is excessive; there is little variation in the weather, which, though hot, is nevertheless not depressing, and the climate for the tropics must be considered remarkably healthy. The rainfall is largest between December and April, but there is so much at other times of the year also that these months hardly deserve the name of the rainy season. During this period north-west winds are frequent, continuing at times for weeks, and there are thunderstorms and hurricanes. These, while not generally destructive, are sometimes so, as notably the storm of the 13th of January 1903. During the eight drier and cooler months south-east trade winds prevail, but there are southerly winds which bring rain, and even westerly breezes are not infrequent. The mean temperature for the year on the coasts is 77° F. (maximum 84°, minimum 69°); and the average rainfall from December to March (4 months) is 29 inches; from April to November (8 months), 19 inches.

Fauna.—Mammals, as in other Polynesian islands, are restricted to a few species of bats (mostly of the genus *Pteropus*), rats and mice, none of them peculiar. Of domestic animals, the pig and the dog—the former a small breed which quickly disappeared before the stronger European strains—were plentiful even in Wallis's days. The ornithology is very poor as compared with that of the Western Pacific; the Society Islands possess no peculiar genera and but few peculiar species. They claim, however, a thrush, several small parrots of great beauty, doves, pigeons, rails and a sandpiper (*Tringa leucoptera*). A jungle-fowl (var. of *Gallus bankiva*) is found in the mountains, but as domesticated fowls were abundant, even when Tahiti was first discovered by Europeans, these wild birds are doubtless the offspring of tame birds. The lagoons swarm with fish of many species. Insects are poor in species, though some of them are indigenous. Crustaceans and molluscs, on the other hand, are well represented; worms, echinoderms, and corals comparatively poorly. A noteworthy feature of Tahitian conchology is the number of peculiar species belonging to the genus *Partula*, almost every valley being the habitat of a distinct form.[1]

Flora.—The flora, though luxuriant and greatly enhancing the beauty of the islands, is not very rich. It is, however, less poor in trees, shrubs and hardwood plants, than in the smaller undergrowth. Orchids, including some beautiful species, and ferns are abundant; but, here as in Polynesia generally, *Rubiaceae* is the order best represented. Remarkable are the banana thickets, which grow at an altitude of from 3000 to 5000 ft. Along the shore—in some places almost to the extinction of all native growth—many exotics have established themselves; and a great variety of fruit-bearing and other useful trees have been introduced.[2]

Inhabitants.—The Tahitians are a typical Polynesian race, closely connected physically with the Marquesans and Rarotongans, but widely divided from them in many of their customs. The dialects, also, of the three groups are different, the Tahitian being perhaps the softest in all Oceania. The women rank with the most beautiful of the Pacific, though the accounts given of them by early voyagers are much exaggerated; and for general symmetry of form the people are unsurpassed by any race in the world. Even now in its decadence, after generations of drunkenness and European disease and vice, grafted on inborn indolence and licentiousness, many tall and robust people (6 ft. and even upwards in height) are to be found. Men and women of good birth can generally be distinguished by their height and fairness, and often, even in early age, by their enormous corpulence. The skin varies from a very light olive to a full dark brown. The wavy or curly hair and the expressive eyes are black, or nearly so; the mouth is large, but well-shaped and set with beautiful teeth; the nose broad (formerly flattened in infancy by artificial means); and the chin well developed.

The native costume was an oblong piece of bark-cloth with a hole in its centre for the head, and a plain piece of cloth round the loins was worn alike by men and women of the higher classes. Men of all ranks wore, with or without these, the T bandage. The women concealed their breasts except in the company of their superiors, when etiquette demanded that inferiors of both sexes should uncover the upper part of the body. The chiefs wore short feather cloaks, not unlike those of the Hawaiians, and beautiful semicircular breastplates, dexterously interwoven with the black plumage of the frigate bird, with crimson feathers and with sharks' teeth; also most elaborate special dresses as a sign of mourning. The priests had strange cylindrical hats, made of wicker-work and over a yard in height. Circumcision, and in both sexes tattooing, were generally practised, and much significance was attached to some of the marks. The houses were long, low, and open at the sides. Household utensils were few—plain round wooden dishes, sometimes on legs, coco-nut shells, baskets, &c. Low stools and head-rests were used. Pottery being unknown, all food was baked in a hole dug in the ground or roasted over the fire. Their chief musical instruments were the nose-flute—often used as the accompaniment of song—and the drum. Conch-shells were also used. Tahitian stone adzes, which are greatly inferior in finish to those of the Hervey Islands, are, like the adzes of Polynesia in general, distinguished from those of Melanesia by their triangular section and adaptation to a socket. Slings were favourite weapons of the Tahitians; they had also plain spears expanding into a wide blade, and clubs. The bow and arrow seem only to have been used in certain ceremonial games. Their canoes, from 20 to 70 ft. in length, were double or single, and provided with sail and outriggers. They were not well finished, but the high curved sterns, rising sometimes to a height of 20 ft., of those destined to carry the images of their gods, were carved with strange figures and hung with feathers. Cannibalism is unknown, though some ceremonies which were performed in connexion with human sacrifices may possibly be survivals of this practice. The staple food of the islanders consisted of the bread-fruit, the taro-root, the yam, the sweet potato, and in some districts the wild plantain; but they also ate much fish (the turtle was considered sacred food), as well as pigs and dogs, though of the latter, as pets, the women were so fond as to suckle the puppies sometimes even to the exclusion of their own children.

Tahitians were good fishermen and bold seamen. They steered by the stars, of which they distinguished many constellations. The land was carefully tended and the fields well irrigated. Three great classes were recognized:—(1) The sovereign, who bore a semi-sacred as well as a political character, and the reigning chiefs of districts; (2) the proprietors and cultivators of inherited land, who also built canoes, made arms, &c.; to these two classes also belonged the priests, who were medicine-men as well; (3) the fishers, artisans, &c., and slaves. As wars and infanticide depopulated the island this class gradually acquired land and with it certain privileges. Rank is hereditary and determined by primogeniture, not necessarily in the male line. The firstborn of a sovereign succeeded at once to titular sovereignty; the father, who was the first to pay homage to his child, then abdicated, and became regent. It is easy to see that, while this custom tended to keep honours within a family, it may have encouraged the practice of infanticide, which was common in all grades of society when Tahiti was first visited by Europeans. The age at which the child's authority became real varied according to his own abilities and the will of his subjects. Though arbitrary, the power of the king was limited by the power of his vassals, the district chiefs, who ruled absolutely over their respective districts, and who might be of as good blood as himself. The king had a councillor, but was alone responsible for any act. The bi-insular form of Tahiti promoted the independence of the chiefs, and war was rarely declared without their being first summoned to council. Their power over their own people was absolute. The form of government was thus strictly feudal in character, but it gradually centralized into a monarchy, which, in the person of Pomare II., the English missionaries greatly helped to regulate and strengthen. The sovereign sent his commands by a messenger, whose credentials were a tuft of coco-nut film. This tuft was returned intact as a sign of assent or torn in token of refusal.

The temples were square tree-surrounded enclosures, with a single entrance and several small courts, within which were houses for the images and attendant priests. A pyramidal stone structure, on which were the actual altars, stood at the further end of the square. In the temples were buried the chiefs, whose embalmed bodies, after being exposed for a time, were interred in a crouching position. Their skulls, however, were kept in the houses of their nearest relations. In the great temple at Atahura the stone structure was 270 ft. long, 94 ft. wide, and 50 ft. high, and its summit was reached by a flight of steps built of hewn coral and basalt. Sacrificial offerings, including human sacrifices, formed a prominent part of Tahitian worship. An eye of the victim was offered to the king, and placed within his mouth by the officiating priest. Every household possessed its own guardian spirits, but there were several superior divinities, of which, at the beginning of the 19th century, Oro was the most venerated. The images, which are less remarkable than those of Hawaii, were rough representations of the human form carved in wood. The *Areoi*, a licentious religious association, was a special feature of Tahitian society.

The Tahitians are light-hearted, frivolous, courteous and generous, but deceitful and cruel. They were always notorious for their immorality, one of their customs being a systematized exchange of wives. Besides dancing, the singing of songs, and the recitation of historical and mythical ballads, the natives had also a variety of sports and games. Wrestling, boxing, and spear-throwing matches, with foot and canoe races, were held; also sham fights and naval reviews. They had several ball games—one (played chiefly by women), a kind of football; but surf-swimming was perhaps the favourite sport, and cock-fighting was much practised.

Products, Trade, Administration.—Papeete, as the emporium for a widely scattered archipelago (including Paumotu, &c.), has an export trade in mother-of-pearl, pearls (mainly from the Paumotu islands), oranges, trepang (for China), copra and vanilla. Many whalers formerly visited Papeete harbour. During the American Civil War, in the middle of the 19th century, Tahitian cotton was put upon the European market, but its cultivation had ceased by 1884, and it has been little grown since. This is also true of coffee and tobacco, among other crops which have been tried. Sugar and rum are also produced.

The importation of "labour," chiefly for the plantations, from other Polynesian islands was placed under government control in 1862. The Tahitians themselves prefer handicrafts to agricultural work, and many are employed as artisans by European masters.

The total value of exports was £140,325 and of imports £127,600 in 1904. Papeete is the seat of government. The French establishments in the Eastern Pacific are administered by a governor, a privy council, and a council including the *maire* of Papeete and the presidents of the chambers of commerce and agriculture.

History.—The discovery and early exploration of the Society Islands is treated under that heading. In 1788, when Lieutenant Bligh in the "Bounty" visited Tahiti, the leading chief was Pomare, whose family had been pre-eminent in the island for

[1] Finsch and Hartlaub, *Fauna Central-Polynesiens*, Halle, 1867.

[2] De Castillo, *Illustrationes Florae Insularum Maris Pacifici*, Paris, 1886.

more than a century. Aided by sixteen of the "Bounty" mutineers, and armed with guns procured from Bligh and a Swedish vessel, Pomare greatly strengthened his power and brought to a successful close a long struggle with Eimeo.

The attempt at colonization by the Spaniards in 1774 was followed by the settlement of thirty persons brought in 1797 by the missionary ship "Duff." Though befriended by Pomare I. (who lived till 1805), they had many difficulties, especially from the constant wars, and at length they fled with Pomare II. to Eimeo and ultimately to New South Wales, returning in 1812, when Pomare renounced heathenism. In 1815 he regained his power in Tahiti. For a time the missionaries made good progress—a printing press was established (1817), and coffee, cotton and sugar were planted (1819); but soon there came a serious relapse into heathen practices and immorality. Pomare II. died of drink in 1824. His successor, Pomare III., died in 1827, and was succeeded by his half-sister Aimata, the unfortunate "Queen Pomare (IV.)." In 1828 a new fanatical sect, the "Mamaia," arose, which gave much trouble to the missions. The leader proclaimed that he was Jesus Christ, and promised to his followers a sensual paradise. In 1836 the French Catholic missionaries in Mangareva attempted to open a mission in Tahiti. Queen Pomare, advised by the English missionary and consul Pritchard, refused her consent, and removed by force two priests who had landed surreptitiously and to whom many of the opposition party in the state had rallied. In 1838 a French frigate appeared, under the command of Abel Dupetit-Thouars, and extorted from Pomare the right of settlement for Frenchmen of every profession. Pritchard opposed this, and caused Pomare to apply for British protection; but this was a failure, and the native chiefs compelled the queen, against her will, to turn to France. A convention was signed in 1843, placing the islands under French protection, the authority of the queen and chiefs being expressly reserved. Dupetit-Thouars now reappeared, and, alleging that the treaty had not been duly carried out, deposed the queen and took possession of the islands. His high-handed action was not countenanced by the French government; but while, on formal protest being made from England, it professed not to sanction the annexation, it did not retrace the steps taken. Two years were spent in reducing the party in the islands opposed to French rule; an attempt to conquer the western islands failed; and at length, by agreement with England, France promised to return to the plan of a protectorate and leave the western islands to their rightful owners. Pomare died in 1877, and her son Ariane (Pomare V.) abdicated in 1880, handing over the administration to France, and in the same year Tahiti, including Eimeo, was proclaimed a French colony. In 1903 the whole of the French establishments in the Eastern Pacific were declared one colony, and the then existing elective general council was superseded by the present administration.

Besides the narratives of early voyages, and general works covering the Society Islands (for which see PACIFIC), see Vincendon-Dumoulin, *Les Iles Tahiti, esquisses historiques et géographiques*, Paris, 1844; A. Gonfil, "Tahiti," in *La France coloniale*, Paris, 1886; H. Le Chartier, *Tahiti*, Paris, 1887; Monchoisy, *La Nouvelle Cythère*, Paris, 1888; G. Collingridge, "Who discovered Tahiti?" in *Journ. Polynesian Soc.*, xii., 1903. Among the narrative works of visitors to Tahiti may be mentioned Pierre Loti, *Le Mariage de Loti*, Paris, 1881; Dora Hort, *Tahiti: the Garden of the Pacific*, London, 1891.

TAHR, the native name of a shaggy-haired brown Himalayan wild goat characterized by its short, triangular and sharply keeled horns. Under the name of *Hemitragus jemlaicus*, it typifies a genus in which are included the wariatu, or Nilgiri ibex (*H. hylocrius*), from the Nilgiri and Anamalai hills of Southern India, and a small species, *H. jayakeri*, from South Arabia. Tahr frequent the worst ground of almost all ruminants.

TAILLANDIER, SAINT-RENÉ (1817–1879), French critic, whose original name was René Gaspard Ernest Taillandier, was born in Paris on the 16th of December 1817. He completed his studies at Heidelberg, and then became professor of literature successively at Strassburg, Montpellier and the Sorbonne, where he was nominated to the chair of French eloquence in 1868. Most of the articles included in his published volumes first appeared in the *Revue des deux mondes*. In January 1870 he became general secretary of the ministry of education, and continued in this office after the fall of the Empire. He became officer of the Legion of Honour in 1870, and was elected to the Academy in 1873. He died in Paris on the 22nd of February 1879.

His works include:—*Allemagne et Russie, études historiques et littéraires* (1856), *Le Poète du Caucase . . . Michel Lermontoff* (1856), *Maurice de Saxe* (2 vols. 1865), *Tchèques et Magyars* (1869), *Le Général Philippe de Ségur* (1875).

TAILLE (from Fr. *tailler*, to cut or divide; late Lat. *taliare*, said to come from *talia*, *talea*), the equivalent of the English *tallage* (*q.v.*), was in France the typical direct tax of the middle ages, just as the word *tonlieu* was the generic term for an indirect tax. Other words used in certain districts in the same sense as *taille* were *queste* (*questa, quista*), *fouage* (*foragium*), *cote*. The essence of the tax denoted by these names was that the amount was fixed *en bloc* for a whole group of persons, and afterwards divided among them in various ways. In ancient French law we find three forms of *taille:* the *taille servile*, *taille seigneuriale*, and *taille royale*.

The *taille servile* can scarcely be termed a tax; it was rather a tax which had degenerated into a source of profit for certain individuals. Every lord who possessed serfs could levy the *taille* on them, and originally this was done arbitrarily (*a volonté*) both as to frequency and amount. It always remained a characteristic feature of serfdom, but was limited and fixed, either by contracts or concessions from the lord (*taille abonnée*), or by the customs.

The *taille seigneuriale* was a true tax, levied by a lord on all his subjects who were neither nobles nor ecclesiastics. But, in our opinion, when feudalism was established, the right of levying it did not belong to every lord, but only to the lord having the *haute justice*. But he levied it by right, without the necessity for any contract between him and those who paid it. He fixed the sum to be paid by each group of inhabitants, who then had to see that it was assessed, collected, and paid to the lord, electing commissaries (*preud hommes*) from among themselves for this purpose. This was reducing the administration of taxation to its simplest form. Custom, however, or an order of the lord generally fixed the principle upon which the division was made. It was often a "hearth tax" (*fouage*), when each fire, *i.e.* each head of a family, paid the same sum, arrived at by dividing the local contingent of the *taille* by the number of fires. But this equality, which took no account of wealth or poverty, was felt to be unjust, and the assessment began to be made according to the resources of each family, "the strong bearing the weak, and the weak relieving the strong." The seigniorial *taille*, like the servile, had the character of a personal tax (*taille personelle*), a rudimentary tax on income, every man being taxed according to his wages or other income. The king originally had only the right of levying the *taille* in places where he had retained the exercise of the *haute justice*. At that time there was no royal *taille*, strictly speaking; it was only the seigniorial *taille* transferred to the crown, but it was one of the first taxes his right to levy which upon all the inhabitants of the domain of the crown, whether serfs or *roturiers*, was recognized. In the course of the 13th century the idea began to prevail that it was fair for the king, in time of war, to levy a *taille* upon the subjects of the lords having the *haute justice* in various parts of the royal domain. Moreover, *tailles* were often granted him by the provincial estates or the states-general. Thus the general *taille*, raised for the benefit of the king, became more and more frequent, and naturally tended to become permanent. This transformation was confirmed, rather than effected, by the *ordonnance* of 1439. Its immediate object was, not the regulation of the *taille*, but the organization of the *compagnies d'ordonnance*, *i.e.* the heavy cavalry which the king from that time on maintained on a permanent footing. Military expenses thus becoming permanent, it was natural that the *taille*, the tax which had long been devoted to meeting the expenses of the royal wars, should also become permanent. This was contained implicitly in the *ordonnance* of 1439, which at the same time suppressed the seigniorial *taille*, as competing too closely with the royal *taille* by imposing a double burden on the taxpayer. A kind of seigniorial *taille* continued to exist besides the servile *taille*, but this kind presupposed a title, a contract between the taxable *roturier* and the lord, or else immemorial possession, which amounted to a title.

The royal *taille* naturally retained the distinctive characteristics of the seigniorial, as can be seen from an examination of the way in which it was assessed and collected; the chief characteristic being that ecclesiastics and nobles, who were exempt from the seigniorial *taille*, were also exempt from the royal. The royal *taille*, though levied by the king by right, did not fall upon the whole kingdom. The *pays d'élections* were subject to it, the *pays d'états* were not (see FRANCE: *Law and Institutions*).

Throughout the *pays d'élections* the *taille* was almost universally personal (*taille personnelle*), *i.e.* a tax on the whole income of the taxpayer, whatever its source. It was also a distributory tax (*impôt de repartition*); every year the king in his council fixed the total sum which the *taille* was to produce in the following year; he drew up and signed the *brevet de la taille* (warrant), and the contribution of the individual taxpayer was arrived at in the last analysis by a series of subdivisions.

The *conseil du roi* first divided the total sum among the various *généralités* (the higher financial divisions), again dividing the amount due from each *généralité* among the *élections* of which it was composed. Then the *élus* in each *élection* divided the contribution due from it among the parishes. The final division took place in the parish or community, among the inhabitants subject to the tax. So far the system remained the same as that of the old seigniorial *taille*. The assessment and collection of it were the business of the community; the crown, in principle, had nothing to do with them and did not bear the cost of a local administration for the purpose. The community had to produce its contingent of the *taille*. In principle it was even held to be the debtor for the amount; hence the inhabitants were jointly responsible, a state of affairs which was not suppressed till the time of Turgot, and even then not completely.

The inhabitants subject to the *taille*, summoned to a general assembly by the syndic, elected commissaries for the assessment (*asséeurs*) and collection (*collecteurs*) of the tax from among themselves. Originally two series were elected, both assessors and collectors. But from 1600 onwards the same persons fulfilled both functions, the object being, by giving the assessors the duty of collecting the tax, to lead to a juster and more conscientious assessment. The system appeared to be admirable, forming in this respect a kind of self-government, but in practice it was frequently oppressive for the taxpayers. The assessors estimated the individual incomes arbitrarily, village quarrels and rivalries leading them to over-charge some and under-charge others, and complaints were numberless on this point. Control should no doubt have been exercised by the *élus*, but they do not seem to have taken this part of their duties very seriously. Payment was rigorously enforced, and thus for a variety of reasons the *taille* was a burdensome and hated tax. It had still further vices: not only were nobles and ecclesiastics exempt from it, but many other privileges had been introduced by law, total or partial exemption extending to a large number of civil and military officials and *employés* of the crown on the *ferme générale*. The towns in general were not subject to it, at least directly; some had been exempt from time immemorial, others (*rédimées*) had purchased exemption for a sum of money, yet others (*abonnées*) had compounded for the tax, *i.e.* instead of paying the *taille* they paid into the royal treasury a sum fixed by contract, which they generally raised by *octrois*, or entrance dues.

Such was the administration of the *taille* until about the middle of the 17th century, after which time, although the broad lines remained the same, important reforms were introduced. They came principally from the provincial *intendants*, or from the *cours des aides*, which were animated by a liberal spirit. The *intendants*, by an exercise of their general or special powers, took the place of the *élus*, and delegated *commissaires aux tailles* (commissaries of the *taille*) for the assessment of the parishes, who guided and supervised the elected collectors—for the most part ignorant and partial peasants. They also endeavoured to distinguish between different kinds of income, in order to arrive at a more just estimate of the total income, and fixed by tariff the proportion in which each kind of income was to contribute. They sometimes settled officially and of their own authority the share of certain taxpayers, and, though this was sometimes done as a favour, it was often a measure of justice. They also tried to limit the scope of privileges. These efforts were inspired by a series of scientific studies and criticisms, chief among which were Vauban's *Dîme royale*, and the *Taille tarifée* of the Abbé de St. Pierre.

In certain districts the *taille* was real (*taille reelle*) *i.e.* a tax on real property. It was not an equal tax falling on all landowners, but the question as to whether a certain estate was to be taxed or not was decided according to the quality of the property, and not that of the owner. The *biens nobles* (*fiefs*) and the *biens ecclesiastiques* were exempt; *tenures roturières*, however, by whomsoever held, were taxed. A small part of the *pays d'élections* was also *pays de taille réele*. But it was the chief form of tax in the *pays d'états*, and even there an attempt had generally been made to check the exemption of nobles' property. It has been shown that in these districts the *taille* had originally been personal, having become real by a curious evolution. In these districts there were *cadastres*, or *compoix-terriers* (land registers), which allowed of a non-arbitrary assessment; and at the end of the *ancien régime* merely needed revision.

In certain provinces where the royal *taille* was levied there were neither *élections* nor *généralités*, and the whole administration of the tax was in the hands of the *intendants*. These were the provinces of the east and north, which were united to the crown at a period when the power of the *intendants* was already fully developed; they were sometimes known as *pays d'imposition*.

See FRANCE: *Law and Institutions*; Henri Sée, *Les Classes rurales et le régime domanial en France au Moyen Âge* (Paris, 1901); and Auger, *Code des tailles* (Paris, 1788). (J. P. E.)

TAILLEFER, the surname of a bard and warrior of the 11th century, whose exact name and place of birth are unknown. He accompanied the Norman army to England in 1066, and obtained permission from William to strike the first blow at the battle of Hastings. He fought with spirit and determination, and was killed in the battle. Mention of Taillefer is made by Guido, bishop of Amiens, in his *Carmen de bello Hastingensi*, v. 931–44 (in *Mon. Hist. Brit.*, 1848) and by Henry of Huntingdon in his *Historia Anglorum* (in *Rer. Brit. med. aevi script.*, p. 763, ed. Arnold, London, 1879); and his prowess is depicted on the Bayeux tapestry. The statement of Wace in the *Roman de Rou*, 3rd part, v. 8035–62, ed. Andresen (Heilbronn, 1879), that Taillefer went before the Norman army singing of Charlemagne and of Roland and the vassals who died at Roncevaux, has been considered important in demonstrating the existence of a comparatively early tradition and song of Roland.

See W. Spatz, *Die Schlacht von Hastings* (Berlin, 1896); Freeman, *History of the Norman Conquest*.

TAILOR (Fr. *tailleur*, from *tailler*, to cut, Lat. *talea*, a thin rod, a cutting for planting), one who cuts out and makes clothes. Formerly the tailor, or *cissor*, made apparel for both men and women, and not merely outer garments, but also articles of linen and the padding and lining of armour—whence the style "Taylors and Linen Armourers" applied to the Merchant Taylors Company of the City of London in their earliest charters. But the word is now generally limited to those who make the outer (cloth) garments for men, and less frequently for women, though a phrase such as "shirt-tailor" is occasionally met with. In modern usage, too, it commonly has the implication that the garments are made to the order, and to the measure, of the individual purchaser, as opposed to ready-made clothing, which means articles of apparel manufactured in large quantities in a series of stock or standard sizes, such that any purchaser may expect to find among them one that will fit him with more or less accuracy. The clothing trade was originally confined to goods of the poorest grades, but it has come, especially in America, to include articles of good, though not of the first, quality. It probably first came into existence at seaport towns, where, to meet the convenience of sailors returning from long voyages and requiring their wardrobes to be replenished at short notice, the "outfitters" kept stocks of ready-made garments on sale; but it made no considerable progress until after the middle of the 19th century, when the introduction of the sewing-machine brought about the possibility of manufacturing in large quantities. Its development was attended with gradually increasing subdivision of labour and, to a large extent, with the disappearance of the tailor as a skilled craftsman. The first step was for a garment, such as a coat, to be completed by the joint efforts of a family. Then followed the "task system," which in America was the result of the influx of Russian Jews that began about 1875. Under it a team of three men, with a "presser" and a girl to sew on the buttons, divided the work between them. Payment was made by the "task," *i.e.* a specified number of garments, the money being divided between the members of the team in certain proportions. Often several teams would be run by a contractor, who naturally selected the cheapest workshops he could find and packed them as full of workers as possible; and when through stress of competition he had to accept lower prices the plan he adopted was to increase the number of garments to a task, leaving the pay unaltered. The result was the introduction of many of the worst features of the "sweating system," the workers having to work excessively long hours in order to finish the task, which in some cases meant as many as twenty coats a day. In the "factory" or "Boston" system the subdivision is still more minute, and as many as one hundred persons may be concerned in the production of one coat. The amount of tailoring skill required in a worker is even further reduced, but the premises come under the regulation of the factory laws. The factory system has also cheapened production in a legitimate way, because it has enabled mechanical power for driving sewing-machines, and also expensive labour-saving machinery, to be introduced to an extent not economically possible in small shops.

TAIN, a royal and police burgh of the county of Ross and Cromarty, Scotland. Pop. (1901) 2076. It is situated on rising ground within a mile of the southern shore of Dornoch Firth, 25½ m. N.E. of Dingwall by the Highland Railway. The name, of which the Tene, Tayne and Thane are older forms, is derived from the Icelandic *thing*, "assembly" or "court." Among the principal buildings are the town hall, court house, public hall, Easter Ross combination poorhouse, and the academy (opened in 1812). The industries include distilling, the making of aerated waters, and woollen manufactures, and the town is important as a market and distributing centre. The rainfall is one of the lowest in the kingdom. Duthac (locally called Duthus), a saint of the 11th century, is believed to have been a native, and the old ruined chapel near the station is supposed to have been his shrine. To the collegiate church of St Duthus, a Decorated building, founded by James III. in 1471, James IV. made several pilgrimages in penance for his father's death. The building was used as the parish church till 1815, when it fell into disrepair, but it was restored between 1871 and 1876. It has monuments to Patrick Hamilton, the martyr, and Thomas Hog (1628–1692), the Scottish divine, for some time a prisoner on the Bass. Three and a half miles S.E. are the remains of the Early English abbey of Fearn, founded at Edderton in 1230 by Farquhar, 1st earl of Ross, and transferred hither in 1338. The chancel, nave and two side chapels exist, and it still serves as the parish church. Patrick Hamilton became titular abbot in 1517, and after his martyrdom the abbey was added to the bishopric of Ross.

TAINE, HIPPOLYTE ADOLPHE (1828–1893), French critic and historian, the son of Jean Baptiste Taine, an attorney, was born at Vouziers on the 21st of April 1828. He remained with his father until his eleventh year, receiving instruction from him, and attending at the same time a small school which was under the direction of M. Pierson. In 1839, owing to the serious illness of his father, he was sent to an ecclesiastical pension at Rethel, where he remained eighteen months. J. B. Taine died on the 8th of September 1840, leaving a moderate competence to his widow, his two daughters, and his son. In the spring of 1841 Taine was sent to Paris, and entered as a boarder at the Institution Mathé, where the pupils attended the classes of the Collège Bourbon. Madame Taine followed her son to Paris. Taine was not slow to distinguish himself at school. When he was but fourteen years old he had already drawn up a systematic scheme of study, from which he never deviated. He allowed himself twenty minutes' playtime in the afternoon and an hour's music after dinner; the rest of the day was spent in work. In 1847, as *vétéran de rhétorique*, he carried off six first prizes in the general competition, the prize of honour, and three accessits; he won all the first school prizes, the three science prizes, as well as two prizes for dissertation. It was at the Collège Bourbon that he formed lifelong friendships with several of his schoolfellows who afterwards were to exercise a lasting influence upon him: among these were Prévost-Paradol, for many years his most intimate friend; Planat, the future "Marcelin" of the *Vie Parisienne*; and Cornélis de Witt, who introduced him to Guizot when the latter returned from England in 1846.

Public education was the career which seemed to lie open to Taine after his remarkable school successes. In 1848 he accordingly took both his *baccalauréat* degrees, in science and letters, and passed first into the École Normale; among his rivals, who passed in at the same time, were About, Sarcey, Libert, and Suckau. Among those of Taine's fellow-students who afterwards made a name in teaching, letters, journalism, the theatre and politics, &c., were Challemel-Lacour, Chassang, Aubé, Perraud, Ferry, Weiss, Yung, Gaucher, Gréard, Prévost-Paradol and Levasseur. Taine made his influence felt among them at once; he amazed everybody not only by his erudition, but by his indefatigable energy; and not only by his prodigious industry, but by his facility both in French and Latin, in verse as well as in prose. He devoured Plato, Aristotle, the Fathers of the Church, and he analysed and classified all that he read. He already knew English, and set himself to master German in order to read Hegel in the original. His brief leisure was devoted to music. The teachers of his second and third years, Deschanel, Géruzez, Berger, Havet, Filon, Saisset and Simon, were unanimous in praising the nobility of his character, the vigour and the fertility of his intellect, the distinction of style with which his work was always stamped; they were equally unanimous in finding fault with his unmeasured taste for classification, abstraction and formula. The director of studies, M. Vacherot, gauged his capacity at the end of his second year with prophetic insight. He prophesied that Taine would be a great savant, adding that he was not of this world, and that Spinoza's motto, "Vivre pour penser," would also be his. In the month of August 1851 he came forward as a candidate for the fellowship in philosophy (*agrégation de philosophie*) in company with his friends Suckau and Cambier. Taine was declared to be admissible, together with five other candidates; but in the end only two candidates were admitted, his friend Suckau and Aubé. This decision created almost a scandal. Taine's reputation had already spread beyond the college. Everybody had taken for granted that he would be admitted first. The fact was that his examiners sincerely considered his ideas to be absurd, his style and method of handling a subject dry and tiresome.

The Minister of Public Instruction, however, judged Taine less severely, and appointed him provisionally to the chair of philosophy at the college of Toulon on 6th October 1851; but he never entered upon his duties, as he did not wish to be so far from his mother, and on 13th October he was transferred to Nevers as a substitute. Two months later, on the 27th December, occurred the *coup d'état*, after which every university professor was regarded with suspicion; many were suspended, others resigned. In Taine's opinion it was the duty of every man, after the plébiscite of the 10th December, to accept the new state of affairs in silence; but the universities were not only asked for their submission, but also for their approbation. At Nevers they were requested to sign a declaration expressing their gratitude towards the President of the Republic for the measures he had taken. Taine was the only one to refuse his endorsement. He was at once marked down as a revolutionary, and in spite of his success as a teacher and of his popularity among his pupils, he was transferred on 29th March 1852 to the lycée of Poitiers as professor of rhetoric, with a sharp warning to be careful for the future. Here, in spite of an abject compliance with the stringent rules imposed upon him, he remained in disfavour, and on 25th September 1852 he was appointed assistant professor of the sixth class at the lycée of Besançon. This time he could bear it no longer, and he applied for leave, which was readily granted him on 9th October 1852, and renewed every year till his decennial appointment came to an end. It was in this painful year, during which Taine worked harder than ever, that the fellowship of philosophy was abolished. As soon as Taine heard of this he at once began to prepare himself for the fellowship in letters, and to work hard at Latin and Greek themes. On 10th April 1852 a decree was published by which three years of preliminary study were necessary before a candidate could compete for the fellowship, but by which a doctor's degree in letters counted as two years. Taine immediately set to work at his dissertations for the doctor's degree; on the 8th June (1852) they were finished, and 150 pages of French prose on the Sensations and a Latin essay were sent to Paris. On the 15th July he was informed that the tendency of his Essay on the Sensations made it impossible for the Sorbonne to accept it, so for the moment he laid this work aside, and on 1st August he began an essay on La Fontaine. He then started for Paris, where an appointment which was equivalent to a suspension awaited him. His university career was over, and he was obliged to devote himself to letters as a profession. In a few months his two dissertations, *De personis Platonicis* and the essay on La Fontaine's fables were finished, and on 30th May 1853 he took his doctor's degree. This was the last act of his university career; his life as a man of letters was now to begin.

No sooner had he deposited his dissertations at the Sorbonne than he began to write an essay on Livy for one of the competitions set by the Academy. Here again the moral tendency of his work excited lively opposition, and after much discussion the competition was postponed till 1855; Taine toned down some of the censured passages, and the work was crowned by the Academy in 1855. The essay on Livy was published in 1856 with the addition of a preface setting forth determinist doctrines, much to the disgust of the Academy. In the beginning of 1854 Taine, after six years of uninterrupted efforts, broke down and was obliged to rest: but he found a way of utilizing his enforced leisure; he let himself be read to, and for the first time his attention was attracted to the French Revolution; he acquired also a knowledge of physiology in following a course of medicine. In 1854 he was ordered for his health to the Pyrenees, and Hachette, the publisher, asked him to write a guide-book of the Pyrenees. Taine's book was a collection of vivid descriptions of nature, historical anecdotes, graphic sketches, satirical notes on the society which frequents watering-places, and underlying the whole book was a vein of stern philosophy; it was published in 1855.

The year 1854 was an important one in the life of Taine. His enforced leisure, the necessity of mixing with his fellow-men, and of travelling, tore him from his cloistered existence and brought him into more direct contact with reality. His method of expounding philosophy underwent a change. Instead of employing the method of deduction, of starting with the most abstract idea and following it step by step to its concrete realization, henceforward he starts from the concrete reality and proceeds through a succession of facts until he arrives at the central idea. His style also became vivid and full of colour; he shows that he is acutely sensible to the outward manifestations of things and depicts them in all their relief. Simultaneously with this change in his works his life became less self-centred and solitary. He lived with his mother in the Isle Saint-Louis, and now he once more associated with his old friends, Planat, Prévost-Paradol and About. He made the acquaintance of Renan, and through Renan that of Sainte-Beuve, and he renewed friendly relations with M. Havet, who for three months had been his teacher at the École Normale. These years (1855–56) were Taine's periods of greatest activity and happiness in production. On 1st February 1855 he published an article on La Bruyère in the *Revue de l'Instruction Publique*. In the same year he published seventeen articles in this review and twenty in 1856 on the most diverse subjects, ranging from Menander to Macaulay. On 1st August 1855 he published a short article in the *Revue des Deux Mondes* on Jean Reynaud. On 3rd July 1856 appeared his first article in the *Débats* on Saint-Simon, and from 1857 onwards he was a constant contributor to that journal. But he was seeking a larger field. On 17th January 1856 his history of English literature was announced, and from 14th January 1855 to 9th October 1856 he published in the *Revue de l'Instruction Publique* a series of articles on the French philosophers of the 19th century, which appeared in a volume at the beginning of 1857. In this volume he energetically attacked the principles which underlie the philosophy of Victor Cousin and his school with an irony which amounts at times to irreverence. The book closes with the sketch of a system in which the methods of the exact sciences are applied to psychological and metaphysical research. The work itself met with instantaneous success, and Taine became famous. Up till that moment the only important articles on his work were an article by About on the *Voyage aux Pyrénees*,[1] and two articles by Guizot on his *Livy*.[2] After the publication of *Les Philosophes Français*, the articles of Sainte-Beuve in the *Moniteur* (9th and 16th March 1856), of Sherer[3] in the *Bibliothèque Universelle* (1858), and of Planche in the *Revue des Deux Mondes* (1st April 1857) show that from this moment he had taken a place in the front rank of the new generation of men of letters. Caro published an attack on Taine and Renan, called "L'Idée de Dieu dans une Jeune École," in the *Revue Contemporaine* of 15th June 1857. Taine answered all attacks by publishing new books. In 1858 appeared a volume of *Essais de Critique et d'Histoire*; in 1860 *La Fontaine et ses Fables*, and a second edition of his *Philosophes Français*. During all this time he was persevering at his history of English literature up to the time of Byron. It was from that moment that Taine's influence began to be felt; he was in constant intercourse with Renan, Sainte-Beuve, Sherer, Gautier, Flaubert, Saint-Victor and the Goncourts, and gave up a little of his time to his friends and to the calls of society. In 1862 Taine came forward as a candidate for the chair of literature at the Polytechnic School, but M. de Loménie was elected in his place.

The following year, however, in March, Marshal Randon, Minister of War, appointed him examiner in history and German to the military academy of Saint Cyr, and on 26th October 1864 he succeeded Viollet-le-Duc as professor of the history of art and æsthetics at the École des Beaux Arts. Renan's appointment at the Collège de France and Taine's candidature for the Polytechnic School had alarmed Mgr. Dupanloup, who in 1863 issued an *Avertissement à la Jeunesse et aux Pères de Famille*, which consisted of a violent attack upon Taine, Renan and Littré: Renan was suspended, and Taine's appointment to Saint Cyr would have been cancelled but for the intervention of the Princess Mathilde. In December 1863 his *Histoire de la Littérature Anglaise* was published, prefaced by an introduction in which Taine's determinist views were developed in the most uncompromising fashion. In 1864 Taine sent this work to the Academy to compete for the Prix Bordin. M. de Falloux and Mgr. Dupanloup attacked Taine with violence; he was warmly defended by Guizot: finally, after three days of discussion, it was decided that as the prize could not be awarded to Taine, it should not be awarded at all. This was the last time Taine sought the suffrages of the Academy save as a candidate, in which quality he appeared once in 1874 and failed to be elected, Mézières, Caro and Dumas being the rival candidates; and twice in 1878, when, after having failed in May, H. Martin being chosen, he was at last elected in November in place of M. Loménie. In 1866 he received the Legion of Honour, and on the conclusion of his lectures in Oxford on Corneille and Racine, the University conferred upon him (1871) its degree of D.C.L.

The period from 1864 to 1870 was perhaps the happiest of Taine's life. He derived pleasure from his employment at the Beaux Arts and Saint Cyr, which left ample leisure for travel and research. In 1864 he spent February to May in Italy, which furnished him with several articles for the *Revue des Deux Mondes* from December 1864 to May 1866. In 1865 appeared *La Philosophie de l'Art*, in 1867 *L'Idéal dans l'Art*, followed by essays on the philosophy of art in the Netherlands (1868), in Greece (1869), all of which short works were republished later (in 1880) as a work on the philosophy of art. In 1865 he published his *Nouveaux Essais de Critique et d'Histoire*; from 1863 to 1865 appeared in *La Vie Parisienne* the notes he had taken for the past two years on Paris and on French society under the sub-title of "Vie et Opinions de Thomas Frédéric Graindorge," published in a volume in 1867, the most personal of his books, and an epitome of his ideas. In 1867 appeared a supplementary volume to his history of English literature, and in January 1870 his *Théorie de l'Intelligence*. In 1868 he married Mademoiselle Denuelle, the daughter of a distinguished architect.

He had made a long stay in England in 1858, and had brought back copious notes, which, after a second journey in 1871, he published in 1872 under the title of *Notes sur l'Angleterre*. On 28th June 1870 he started to visit Germany, but his journey was abruptly interrupted by the outbreak of the war; his project had to be abandoned, and Taine, deeply shaken by the events of 1870, felt that it was the duty of every Frenchman to work solely in the interests of France. On 9th October 1870 he

[3] Reprinted in *Mélanges de Critique Religieuse*.

published an article on "L'Opinion en Allemagne et les Conditions de la Paix," and in 1871 a pamphlet on *Le Suffrage Universel;* and it was about this time also that the more or less vague ideas which he had entertained of writing on the French Revolution returned in a new and definite shape. He determined to trace in the Revolution of 1789 the reason of the political instability from which modern France was suffering. From the autumn of 1871 to the end of his life his great work, *Les Origines de la France Contemporaine*, occupied all his time, and in 1884 he gave up his professorship in order to devote himself wholly to his task; but he succumbed before it was finished, dying in Paris on 5th March 1893. In the portion of the work which remained to be finished Taine had intended to draw a picture of French society and of the French family, and to trace the development of science in the 19th century. He had also planned a complementary volume to his *Théorie de l'Intelligence*, to be entitled *Un Traité de la Volonté.*

The *Origines de la France Contemporaine*, Taine's monumental achievement, stands apart from the rest of his work. His object was to explain the existing constitution of France by studying the more immediate causes of the present state of affairs—the last years of what is called the *Ancien Régime*, the Revolution and the beginning of the 19th century, to each of which several volumes were assigned. He also had another object, although he was perhaps hardly conscious of it, which was to study man in one of his pathological crises; for Taine makes an investigation into human nature, and the historian checks and endorses the pessimism and misanthropy of Graindorge. The problem which Taine set himself was to inquire why the centralization of modern France is so great that all individual initiative is practically non-existent, and why the central power, whether it be in the hands of a man or of an assembly, is the sole and only power; also to expose the error underlying two prevalent ideas:—(1) That the Revolution destroyed absolutism and set up liberty; the Revolution, he points out, merely caused absolutism to change hands. (2) That the Revolution destroyed liberty instead of establishing it; that France was less centralized before 1789 than after 1800. This also he shows to be untrue. France was already a centralized country before 1789, and grew rapidly more and more so from the time of Louis XIV. onwards. The Revolution merely gave it a new form.

The *Origines* differ from the rest of Taine's work in that, although he applies to a period of history the method which he had already applied to literature and the arts, he is unable to approach his subject in the same spirit; he loses his philosophic calm; he cannot help writing as a man and a Frenchman, and he lets his feelings have play; but what the work loses thus in impartiality it gains in life.

Taine was the philosopher of the epoch which succeeded the era of romanticism in France. The romantic era had lasted from 1820 to 1850. It had been the result of a reaction against the classical school, or rather against the conventionality and lifeless rules of this school in its decadence. The romantic school introduced the principle of individual liberty both as regards matter and style; it was a brilliant epoch, rich in men of genius and fruitful of beautiful work, but towards 1850 it had reached its decline, and a young generation, tired in turn of its conventions, its hollow rhetoric, its pose of melancholy, arose, armed with new principles and fresh ideals. Their ideal was truth; their watchword liberty; to get as near as possible to scientific truth became their object. Taine was the mouthpiece of this period, or rather one of its most authoritative spokesmen.

Many attempts have been made to apply one of Taine's favourite theories to himself, and to define his predominant and preponderant faculty. Some critics have held that it was the power of logic, a power which was at the same time the source of his weakness and of his strength. He had a passion for abstraction. "Every man and every book," he said, "can be summed up in three pages, and those three pages can be summed up in three lines." He considers everything as a mathematical problem, whether it be the universe or a work of art: "C'est beau comme un syllogisme," he said of a sonata of Beethoven. Taine's theory of the universe, his doctrine, his method of writing criticism and history, his philosophical system, are all the result of this logical gift, this passion for reasoning, classification and abstraction. But Taine's imaginative quality was as remarkable as his power of logic; hence the most satisfactory definition of Taine's predominating faculty would be one which comprehended the two gifts. M. Lemaître gave us this definition when he called Taine a *poète-logicien;* M. Bourget likewise when he spoke of Taine's *imagination philosophique*, and M. Barrès when he said that Taine had the power of dramatizing abstractions. For Taine was a poet as well as a logician; and it is possible that the portion of his work which is due to his poetic and imaginative gift may prove the most lasting.

Taine's doctrine consisted in an inexorable determinism, a negation of metaphysics; as a philosopher he was a positivist. Enamoured as he was of the precise and the definite, the spiritualist philosophy in vogue in 1845 positively maddened him. He returned to the philosophy of the 18th century, especially to Condillac and to the theory of transformed sensation. Taine presented this philosophy in a vivid, vigorous and polemical form, and in concrete and coloured language which made his works more accessible, and consequently more influential, than those of Auguste Comte. Hence to the men of 1860 Taine was the true representative of positivism.

Taine's critical work is considerable; but all his works of criticism are works of history. Hitherto history had been to criticism as the frame is to the picture; Taine reversed the process, and studied literary personages merely as specimens and productions of a certain epoch. He started with the axiom that the complete expression of a society is to be found in its literature, and that the way to obtain an idea of a society is to study its literature. The great writer is not an isolated being; he is the result of a thousand causes; firstly, of his race; secondly, of his environment; thirdly, of the circumstances in which he was placed while his talents were developing. Hence Race, Environment, Time—these are the three things to be studied before the man is taken into consideration. Taine completed this theory by another, that of the *predominating faculty*, the *faculté maîtresse.* This consists in believing that every man, and especially every great man, is dominated by one faculty so strong as to subordinate all others to it, which is the centre of the man's activity and leads him into one particular channel. It is this theory, obviously the result of his love of abstraction, which is the secret of Taine's power and of his deficiencies. He always looked for this salient quality, this particular channel, and when he had once made up his mind what it was, he massed up all the evidence which went to corroborate and to illustrate this one quality, and necessarily omitted all conflicting evidences. The result was an inclination to lay stress on one side of a character or a question to the exclusion of all others.

Taine served science unfalteringly, without looking forward to any possible fruits or result. In his work we find neither enthusiasm nor bitterness, neither hope nor yet despair; merely a hopeless resignation. The study of mankind was Taine's incessant preoccupation, and he followed the method already described. He made a searching investigation into humanity, and his verdict was one of unqualified condemnation. In "Thomas Graindorge" we see him aghast at the spectacle of man's brutality and woman's folly. In man he sees the primeval savage, the gorilla, the carnivorous and lascivious animal, or else the maniac with diseased body and disordered mind, to whom health, either of mind or body, is but an accident. Taine is appalled by the *bête humaine;* and in all his works we are conscious, as in the case of Voltaire, of the terror with which the possibilities of human folly inspire him. It may be doubted whether Taine's system, to which he attached so much importance, is really the most lasting part of his work, just as it may be doubted whether a sonata of Beethoven bears any resemblance to a syllogism. For Taine was an artist as well as a logician, an artist who saw and depicted what he saw in vital and glowing language. From the artist we get his essay on La Fontaine, his articles on Balzac and Racine, and the passages on Voltaire and Rousseau in the *Ancien Régime*. Moreover, not only was Taine an artist who had not escaped from the influence of the romantic tradition, but he was by his very method and style a romanticist. His emotions were deep if not violent, his vision at times almost lurid. He sees everything in startling relief and sometimes in exaggerated outline, as did Balzac and Victor Hugo. Hence his predilection for exuberance, strength and splendour; his love of Shakespeare, Titian and Rubens; his delight in bold, highly-coloured themes.

Taine's influence was great, and twofold. On his own generation it was considerable; during the epoch in which he lived, while a wave of pessimism was sweeping over French literature, he was the high priest of the cult of misanthropy, in which even science was held to be but an idol, worthy of respect and devotional service, but not of faith. In its turn came the reaction against positivism and pessimism, and an attempt at spiritual renascence. Around a man so remarkable as Taine a school is certain to form itself; Taine's school, which was one of positivist doctrines, rigid systems and resigned hopelessness, was equally certain to produce at some time or another a school of determined opponents to its doctrines and system. If, therefore, the tone which pervades the works of Zola, Bourget and Maupassant can be immediately attributed to the influence we call Taine's, it is also the influence of Taine which is one of the ultimate causes of the protest embodied in the subsequent reaction.

(M. Ba.)

Bibliography.—The official life, *H. Taine, sa vie et sa correspondance*, was published in 3 vols. in 1902–5 (Eng. trans. by Mrs. R. L. Devonshire, 1902–8). His friend, M. E. Boutmy, published an appreciative study of Taine's philosophy in his *Taine, Scherer, Laboulaye* (Paris, 1901). See also A. Sorel, *Nouveaux essais d'histoire et de critique* (1898); Gabriel Monod, *Les Maîtres de l'histoire* (Paris, 1894); Émile Faguet, *Politiques moralistes au XIXe siècle* (Paris, 1900); P. Lacombe, *La psychologie des individus et des sociétés chez Taine* (1906); P. Nève, *La philosophie de Taine* (1908); and especially Victor Giraud, *Essai sur Taine, son œuvre et son influence, d'après des documents inédits* (2nd ed., 1902); V. Giraud, *Bibliographie de Taine* (Paris, 1902). A comprehensive list of books and articles on Taine is given in H. P. Thieme's *Guide bibliographique de la littérature française de* 1800 *à* 1906 (Paris, 1907). More recently, Taine's historical work has been adversely criticized, especially by A. Aulard in lectures delivered at the Sorbonne in 1905–6 and 1906–7 (*Taine, historien de la révolution française*, 1907), devoted to destructive criticism of Taine's work on the French Revolution.

TAIREN, or Dairen (Russian *Dalny*), a free port created by the Russian government and opened to foreign trade in 1901, situated on the Central Manchurian railway, and thus one of the Pacific termini of the Trans-Siberian railway. It stands at the head of Talien-wan Bay, on the east side of Liao-tung peninsula, in Manchuria, about 20 m. N.E. of Port Arthur. The harbour is roomy, easy of entrance, and free from ice all the year round. The town is situated along the front of the harbour and occupies the slope leading up to the hills at the rear. It is designed to accommodate 30,000 inhabitants and is separated from the Chinese quarter by a large natural park. The climate is temperate and healthy. Tairen is provided with wharves to accommodate the largest ocean steamers, the wharves having a vertical face with 28 ft. depth at low water. The area of the port is 132 acres, and the inner harbour is protected by a stone and concrete breakwater 5950 ft. long. At an early period in the Russo-Japanese war (28th of May 1904), Dalny was occupied by the Japanese after slight resistance.

TAIT, ARCHIBALD CAMPBELL (1811–1882), Anglican divine, archbishop of Canterbury, was born at Edinburgh on the 21st of December 1811. His parents were Presbyterians, but he early turned towards the Scottish Episcopal Church, and was confirmed in his first year at Oxford, having entered Balliol College in October 1830 as a Snell exhibitioner from the University of Glasgow. He won an open scholarship, took his degree with a first-class *in literis humanioribus* (1833), and became fellow and tutor of Balliol; he was also ordained deacon (1836) and priest (1838), and served the curacy of Baldon. Rapid changes among the fellows found him at the age of twenty-six "the senior and most responsible of the four Balliol tutors." The experience gained during this period stood him in good stead afterwards as a member of the first Oxford University Commission (1850–52). He never sympathized with the principles of the Tractarian movement, and on the appearance of Tract XC. in 1841 he drafted the famous protest of the "Four Tutors" against it; but this was his only important contribution to the controversy. On the other hand, although his sympathies were on the whole with the liberal movement in the university, he never took a lead in the matter. In 1842 he became an undistinguished but useful successor to Arnold as headmaster of Rugby; and a serious illness in 1848, the first of many, led him to welcome the comparative leisure which followed upon his appointment to the deanery of Carlisle in 1849. His life there, however, was one of no little activity; he served on the University Commission, he restored his cathedral, and did much excellent pastoral work. There too he suffered the great sorrow of his life. He had married Catharine Spooner at Rugby in 1843; in the spring of 1856, within five weeks, five of their children were carried off by virulent scarlet fever. Not long afterwards he was consecrated bishop of London on the 22nd of November 1856, as successor to C. J. Blomfield. His translation to Canterbury in 1868 (he had refused the archbishopric of York in 1862) constituted a recognition of his work, but made no break in it. His last years were interrupted by illness and saddened by the death in 1878 of his only son Craufurd, and of his wife.

If Blomfield had almost remodelled the idea of a bishop's work, his successor surpassed him. Tait had all Blomfield's earnestness and his powers of work, with far wider interests. Blomfield had given himself zealously to the work of church-building; Tait followed in his steps by inaugurating (1863) the Bishop of London's Fund. He devoted a very large part of his time at London in actual evangelistic work; and to the end his interest in the pastoral side of the work of the clergy was greater than anything else. With his wife, he was instrumental in organizing women's work upon a sound basis, and he did not a little for the healthful regulation of Anglican sisterhoods during the formative period in which this was particularly necessary. Nor was he less successful in the larger matters of administration and organization, which brought into play his sound practical judgment and strong common-sense. He was constant in his attendance in parliament, and spared no pains in pressing on measures of practical utility. The modification of the terms of clerical subscription (1865), the new lectionary (1871), the Burials Act (1880) were largely owing to him; for all of them, and especially the last, he incurred much obloquy at the time. The Royal Commissions on Ritual (1867) and on the Ecclesiastical Courts (1881) were due to him, and he took a large part in the deliberations of both. Probably his successor (see Benson, E. W.) was brought into closer relations with the colonial churches than Tait was; but the healthy development of the Lambeth Conferences on the lines of mutual counsel rather than of a hasty quasi-synodic action was largely due to him.

On the other hand, Tait was not successful in dealing with matters which called for the higher gifts of a ruler, and especially in his relations with (*a*) the liberal trend in modern thought, and (*b*) the Catholic revival. (*a*) As regards the former, he was himself not a little in sympathy with it. But although well-read, he was no scholar in the true sense, and had neither the knowledge to feel sure of his ground nor the theological insight to perceive the real point at issue. His object in dealing with questions of faith, as in dealing with the ritual question, was primarily a practical one: he wished to secure peace, and obedience to the law as he saw it. Consequently, after his sympathies had led him to express himself favourably towards some movement, he frequently found himself compelled to draw back. He expressed a qualified sympathy with some of the writers of *Essays and Reviews*, and then joined in the censure of it by the bishops (1861). The same kind of apparent vacillation was found in his action in other cases; *e.g.*, in the Colenso case

(1863), and in the controversy as to the use or disuse of the Athanasian symbol (1872). It was naturally and widely misunderstood. Some who did not know him thought, or pretended to think, that he was a Socinian or a free-thinker. The world at large knew better; but even Temple warned him, in the case of *Essays and Reviews*, "You will not keep friends if you compel them to feel that in every crisis of life they must be on their guard against trusting you." (*b*) As regards the second point, Tait was concerned with it during the whole of his episcopate, and above all on the side of ritual, on which it naturally came into most direct conflict with the recognized ecclesiastical practice of the day. He had to deal with the St George's-in-the-East riots in 1859, and the troubles at St Alban's, Holborn, in their earlier stages (1867); he took part as assessor in the Privy Council judgment in the Ridsdale case (1877); he was more closely concerned than any other bishop with the agitation against confession in 1858, and again in 1877. His method throughout was the same: he endeavoured to obtain a compliance to the law as declared by the courts; failing this, he made the most earnest efforts to secure obedience to the ruling of the Ordinary for the sake of the peace of the Church; after this, he could do nothing. He did not perceive how much of reason the "ritualists" had on their side: that they were fighting for practices which, they contended, were covered by the letter of the rubric; and that, where rubrics were notoriously disregarded on all hands, it was not fair to proceed against one class of delinquent only. In fact, if others were inclined to ignore it altogether, Tait could hardly realize anything but the connexion between the English Church and the State. From such a position there seemed to be no escape but in legislation for the deprivation of the recalcitrant clergy; and the Public Worship Regulation Act (1874) was the result. For this Tait was by no means responsible as a whole: some of the provisions which proved most irksome were the result of amendments by Lord Shaftesbury which the bishops were unable to resist; and it must be borne in mind that the most disastrous results of the measure were not contemplated by those who were instrumental in passing it. The results followed inevitably: clergy were cited before a new tribunal, and not only deprived but imprisoned. A widespread feeling of indignation spread not only among High Churchmen, but among many who cared little or nothing for the ritual practices involved; and it seemed impossible to foretell what the outcome would be. But the aged archbishop was moved as much as anybody, and tried hard to mitigate such a state of things. At length, when the Rev. A. H. Mackonochie was on the point of being deprived of his benefice of St. Alban's, Holborn, for contumacy, the archbishop, then on his deathbed at Addington, took steps which resulted in the carrying out of an exchange of benefices (which had already been projected), which removed him from the jurisdiction of the court. This proved to be the turning-point; and although the ritual difficulty by no means ceased, it was afterwards dealt with from a different point of view, and the Public Worship Regulation Act became practically obsolete. The archbishop died on the 3rd of December (Advent Sunday), 1882, leaving a legacy of peace to the Church.

Tait was a Churchman by conviction; but although the work of his life was all done in England, he remained a Scotsman to the end. It was the opinion of some that he never really understood the historical position of the English Church and took no pains to learn. John Tillotson, one of his predecessors in the archbishopric, was a favourite hero of his, and in some ways the two men resembled one another. But Tait had none of Tillotson's gentleness, and he rode roughshod over the obstacles in his way. He cannot be called a great ecclesiastical statesman, but he administered his office well and was undoubtedly one of the foremost public men of his day.

See R. T. Davidson and D. Benham, *Life of Archbishop Tait*, 2 vols. (1891); A. C. Tait, *Catharine and Craufurd Tait* (1880). (W. E. Co.)

TAIT, ARTHUR FITZWILLIAM (1819–1905), American artist, was born near Liverpool, England, on the 5th of August 1819. He emigrated to the United States in 1850, and was identified with the art life of New York until his death. In 1858 he was elected to full membership in the National Academy of Design, New York. He died at Yonkers, New York, on the 28th of April 1905. He painted barnyard fowls and wild birds as well as sheep and deer, with great dexterity, and reproductions of his minute panels of chickens had an enormous vogue.

TAIT, PETER GUTHRIE (1831–1901), Scottish physicist, was born at Dalkeith on the 28th of April 1831. After attending the Academy at Edinburgh and spending a session at the University, he went up to Cambridge as a member of Peterhouse, and graduated as senior wrangler and first Smith's prizeman in 1852. As a fellow and lecturer of his college he remained in Cambridge for two years longer, and then left to take up the professorship of mathematics at Queen's College, Belfast. There he made the acquaintance of Thomas Andrews, whom he joined in researches on the density of ozone and the action of the electric discharge on oxygen and other gases, and by whom he was introduced to Sir W. R. Hamilton and quaternions. In 1860 he was chosen to succeed his old master, J. D. Forbes, as professor of natural philosophy at Edinburgh, and this chair he occupied till within a few months of his death, which occurred on the 4th of July 1901, at Edinburgh. The first scientific paper that appears under Tait's name only was published in 1860. His earliest work dealt mainly with mathematical subjects, and especially with quaternions (*q.v.*), of which he may be regarded as the leading exponent after their originator, Hamilton. He was the author of two text-books on them—one an *Elementary Treatise on Quaternions* (1867), written with the advice of Hamilton, though not published till after his death, and the other an *Introduction to Quaternions* (1873), in which he was aided by Professor Philip Kelland (1808–1879), who had been one of his teachers at Edinburgh. In addition, quaternions was one of the themes of his address as president of the mathematical section of the British Association in 1871. But he also produced original work in mathematical and experimental physics. In 1864 he published a short paper on thermodynamics, and from that time his contributions to that and kindred departments of science became frequent and important. In 1871 he emphasized the significance and promise of the principle of the dissipation of energy. In 1873 he took thermoelectricity for the subject of his discourse as Rede lecturer at Cambridge, and in the same year he presented the first sketch of his well-known thermoelectric diagram before the Royal Society of Edinburgh. Two years later researches on "Charcoal Vacua" with J. Dewar led him to see the true dynamical explanation of the Crookes radiometer in the largeness of the free path of the molecule of the highly rarefied air. From 1879 to 1888 he was engaged on difficult experimental investigations, which began with an inquiry into the corrections required, owing to the great pressures to which the instruments had been subjected, in the readings of the thermometers employed by the "Challenger" expedition for observing deep-sea temperatures, and which were extended to include the compressibility of water, glass and mercury. Between 1886 and 1892 he published a series of papers on the foundations of the kinetic theory of gases, the fourth of which contained what was, according to Lord Kelvin, the first proof ever given of the Waterston-Maxwell theorem of the average equal partition of energy in a mixture of two different gases; and about the same time he carried out investigations into impact and its duration. Many other inquiries conducted by him might be mentioned, and some idea may be gained of his scientific activity from the fact that a selection only from his papers, published by the Cambridge University Press, fills three large volumes. This mass of work was done in the time he could spare from his professorial teaching in the university. In addition, he was the author of a number of books and articles. Of the former, the first, published in 1896, was on the dynamics of a particle; and afterwards there followed a number of concise treatises on thermodynamics, heat, light, properties of matter and dynamics, together with an admirably lucid volume of popular lectures on *Recent Advances in Physical Science*. With Lord Kelvin he collaborated in writing the well-known *Treatise on Natural Philosophy*. "Thomson and Tait," as it is familiarly called ("T and T′" was the authors' own formula), was planned soon after Lord Kelvin became acquainted with Tait, on the latter's appointment to his professorship in Edinburgh, and it was intended to be an all-comprehensive treatise on physical science, the foundations being laid in kinematics and dynamics, and the structure completed with the properties of matter, heat, light, electricity and magnetism. But the literary partnership ceased in about eighteen years, when only the first portion of the plan had been completed, because each of the members felt he could work to better advantage separately than jointly. The friendship, however, endured for the twenty-three years which yet remained of Tait's life.

Tait collaborated with Balfour Stewart in the *Unseen Universe*, which was followed by *Paradoxical Philosophy*. Among his articles may be mentioned those which he wrote for the ninth edition of this Encyclopaedia on Light, Mechanics, Quaternions, Radiation and Thermodynamics, besides the biographical notices of Hamilton and Clerk Maxwell.

TAJIK, or PARSIWAN, a subject race of Afghanistan. Underlying the predominant Pathan elements in the country, the Tajik (Tajak, or Tausik) represents the original Persian possessor of the soil, who still speaks his mother tongue and therefore calls himself Parsiwan. There are pure Persians in Afghanistan, such as the Kizilbashes of Kabul and the Naoshirwanis of Kharan; but the name Tajik (= "stranger") appears to be applied only to an admixture of original Arab and Persian stock, who are the slaves of the community—hewers of wood and drawers of water. Everywhere the Tajiks are the cultivators in rural districts, and the shopkeepers and clerks in the towns. They are a fine, athletic people, generally fair in complexion, and assimilate in aspect, in dress, and much in manners to the Afghans, but they are never nomadic. The Tajik is as much the slave of the Pathan in Afghanistan as is the Hindki (whose origin is similar) in the plains of the Indus. Yet the Tajik population of the richly-cultivated districts north of Kabul proved themselves to be of good fighting material in the Afghan war of 1879–80, and the few Kizilbashes that are to be found in the Indian army are brave soldiers. The number of the Tajiks in Afghanistan is estimated at 900,000.

The name itself originally occurs in the Pahlavi writings, and is explained to mean, first, the Arabs in general, then their descendants born in Persia and elsewhere out of Arabia, and, lastly, the Persians in general and their descendants born in Turkestan and elsewhere out of Persia. Tajik thus came to be the collective name of all communities of Iranian stock and Persian speech wherever found in Central Asia. These are co-extensive with the former eastward and northward limits of the Persian empire; but, after the ascendancy of the Turki races, they became the subject element in Turkestan, Afghanistan, Bokhara, Khiva, Kashgaria, while still politically dominant in Badakshan, Wakhan, Darwaz, Kost and Karateghin. In most of these places the Tajiks, with the kindred Galchas, seem to form the bulk of the population, the distinction being that "Tajik" is applied rather to the settled and more civilized lowlanders of modern Persian speech, "Galcha" to the highlanders of Ferghana, Kohistan, Wakhan, &c., who speak either archaic forms of Persian or dialects intermediate between the Iranian and Sanskritic branches of the Indo-European linguistic family.

But, although mainly of Iranian stock, with light complexion and regular features, the Tajiks claim Arab descent, regarding the district about Bagdad as their primeval home, and considering themselves the descendants of the Arabs who overran Central Asia in the first century of the Hejira. At the same time, "it is evident that the inhabitants of the greater part of this region (Central Asia) must from an early period have come in contact with the successive waves of Turkish (Tûrki) and even Mongol population which broke over them; accordingly we find that, although the type is essentially Iranian, it has undergone a certain modification" (Capt. J. M. Trotter, *Bokhâra*, p. 169). The term Tajik must be distinguished from *Sarte*, the latter simply meaning "trader" or "shopkeeper," and being applied indiscriminately to the settled as opposed to the nomad element, and especially to the urban populations, of whatever race, in Central Asia. The Tajiks are known as Tâts on the west side of the Caspian (Baku, Lenkoran, &c.).

TAKHTSINGJI (1858–1896), Maharaja of Bhaunagar, a Rajput chief of the Gohel clan, and the ruler of a state in Kathiawar, was born on the 6th of January 1858, and succeeded to the throne of Bhaunagar on the death of his father, Jaswantsingji, in 1870. During his minority, which ended in 1878, he was educated at the Rajkot college and afterwards under an English officer, while the administration of the state was conducted jointly by Mr. E. H. Percival, a member of the Indian Civil Service, and Azam Gowrishankar Yodeyshankar, C.S.I., one of the foremost native statesmen of India, who had served the state in various capacities since 1822. At the age of twenty Takhtsingji found himself the ruler of a territory nearly 3000 square miles in extent. His first public act was to sanction a railway connecting his territory with one of the main trunk lines, which was the first enterprise of its kind on the part of a raja in western, if not in all, India. The commerce and trade, and the economic and even social development of the state, which came in the wake of this railway, confirmed Takhtsingji in a policy of progressive administration, under which educational establishments, hospitals and dispensaries, trunk roads, bridges, handsome edifices and other public works grew apace. In 1886 he inaugurated a system of constitutional rule, by placing several departments in the hands of four members of a council of state under his own presidency. This innovation, which had the warm support of the governor of Bombay, Lord Reay, provoked a virulent attack upon the chief, who brought his defamers to trial in the High Court of Bombay. The punishment of the ringleaders broke up a system of blackmailing to which rajas used to be regularly exposed, and the public spirit of Takhtsingji in freeing his brother chiefs from this evil was widely acknowledged throughout India, as well as by the British authorities. In 1886 he was created G.C.S.I.; and five years later his hereditary title of thakore was raised to that of maharaja. In 1893 he took the occasion of the opening of the Imperial Institute by Queen Victoria to visit England in order to pay personal homage to the sovereign of the British Empire, on which occasion the University of Cambridge conferred on him the degree of LL.D. He died in 1896. (M.M.BH.)

TAKIN, the Mishmi name of a remarkable hollow-horned ruminant (*Budorcas taxicolor*), the typical representative of which inhabits the Mishmi Hills, in the south-east corner of Tibet, immediately north of the Assam Valley, while a second form is found further east, in the Moupin district. The takin, which may be compared in size to a Kerry cow, is a clumsily built brute with yellowish-brown hair and curiously curved horns, which recall those of the South African white-tailed gnu. Its nearest relatives appear to be the serows of the outer Himalaya and the Malay countries, which are in many respects intermediate between goats and antelopes, but it is not improbably also related to the musk-ox (*q.v.*). As it lacks the thick woolly coat of the two Tibetan antelopes known as the chiru and the goa, there can be little doubt that it inhabits a country with a less severe climate than that of the Central Tibetan plateau, and it is probably a native of the more or less wooded districts of comparatively low elevation forming the outskirts of Tibet. It is remarkable for the shortness of the cannon-bones of the legs, in which it resembles the Rocky Mountain goat.

TAKLA MAKAN, the Central Asian desert which lies between the N. foot of the Kuen-lun ranges and the wide curve of the Tarim river on the W., N., and E. It appears to be naturally divisible into two parts by the river Khotan-darya, and the name applied to the western part between that river and the Yarkand-darya (Tarim) is the desert of Takla Makan proper, while the part between the Khotan-darya and the line of the lower Tarim and the Cherchen-darya is known as the desert of Cherchen. The former is occupied almost entirely by sand-dunes. Sand mountains range in altitude from 60 ft. up to as much as 300 ft. The only breaks in this "sea of sand-waves" are a few small patches of alluvial clay. Often two distinct systems of dunes can be distinguished; one system, consisting of the larger concatenations, stretches from E. to W., while the secondary or transverse dunes run from N. to S. or from N.E. to S.W. The steeper faces of the dunes and of the dune-accumulations are for the most part turned towards the S., the S.W. and the W., that is, invariably away from the direction of the prevailing winds; but in some parts the steep faces are those fronting the E. and the S. In the desert of Cherchen, however, where the general height of the dunes in the N.E. is uniformly greater than in the desert of Takla Makan proper, reaching up to 350 ft., the configuration is complicated by the appearance of elongated expanses of level clay called *bayirs*, varying in size from half a mile to a dozen miles in length, barren and tinged with saline deposits in the middle, with scanty vegetation around, and lofty sand-dunes overhanging them on both sides. These elliptical, cauldron-shaped basins all stretch from N.E. or E.N.E. to S.W. or W.S.W., and are arranged in long curving chains, the successive depressions being parted by transverse ridges of sand. They owe their configuration in great part, perhaps entirely, to the prevailing wind.

On perfectly level ground the dunes are crescentic in shape, have a steep face towards the W., are highest in the centre, and slope away in each direction towards the two horns or cusps of the crescent. On the windward side they have a convex, spoon-shaped slope, regularly formed, but crumpled by tiny sand-waves or ripple-marks. "With regard to the large accumulations of sand (in the desert of Cherchen) we have ascertained the following laws—(1) In the N. of the desert they turn their steep faces towards the N.W., in the middle towards the W.N.W., and in the S. towards the W. and W.S.W.; (2) their eastern slopes ascend rather slowly towards their crests; (3) on the other side their steep leeward faces go down sheer at an angle of 33°, or else in two or three steps; (4) their mass diminishes towards the S.; (5) they are each built up of an innumerable number of individual dunes; (6) although their relief is influenced by winds from other quarters than the predominant, their mass is unaffected by them; (7) it is their varying breadths which give rise originally to the thresholds, and consequently to the formation of the bayirs" (Sven Hedin, *op. cit.* i. 362).

The bayirs become progressively rarer, less distinct, and smaller in size as one advances from E. to W. At the same time the arrangement of the sand-dunes grows more and more irregular, and the dunes themselves plunge steeply down towards the W., the S., and the S.W., and are drawn out towards the N.N.E. and S.S.W., the N. and S. and the N.W. and S.E. In that part of the desert two systems of dunes are distinguishable, intersecting or rather crossing over one another diagonally or at right angles. In the extreme west, at Ordan-Padshah, between Kashgar and Yarkand, the dunes travel annually some 13 ft. towards the S.E., not towards the S.W. The principal cause of the difference between the arrangement of the sand-dunes in the desert of Cherchen and the arrangement of the sand-dunes in the desert of Takla Makan proper in the W. is the wind. In the latter, winds from several quarters co-operate to mould the relief of the desert into capricious and changing outlines; but in the E. the wind blows not only with greater regularity from one settled direction, the N.E. or E.N.E., but also with much greater violence. Indeed, it is in the open Lop country, where the mountains, the Kuruk-tagh on the N., and the Astin-tagh on the S., are the nearest to each other, that the wind develops its greatest and most concentrated energy.[1] In the E., where the sand waves are most exposed to the fiercest wind, they form elongated waves, distinctly outlined, corresponding to the breakers of the ocean. They disseminate themselves westwards over the desert in ever-widening concentric circles. The curving courses of the Tarim and the Koncheh-darya are the only check upon the invasion of the Takla Makan by the sand which is generated in the desert of Lop or further E. and N. in the mountains which girdle the desert of Gobi. But the former river is itself encroaching upon the N.E. margin of the desert, and pressing more and more towards the S.W.

With regard to the origin of the stupendous masses of sand that fill the basin of the Tarim, K. Bogdanovich considers them to consist for the most part of the disintegrated products of the fine-grained alluvial clays of the desert itself. On the other hand, G. N. Potanin and V. A. Obruchev both seek for its origin in the hard rocks of the mountains which encircle the deserts; and in this view, subject to certain modifications, Sven Hedin is disposed to agree. But he adds[2] that the masses of sand themselves "are derived from three separate sources, in part directly, in part indirectly—(1) the direct transportation by the wind of the products of disintegration from the adjacent mountains, whether sandstones or crystalline rocks; (2) through the activity of the wind operative amongst the arenaceous alluvia of the rivers and temporary lakes; (3) through the sand that was already present in the soil, and which became exposed in rings more or less concentric in proportion as the former (Central Asian Mediterranean) sea dried up." Of these agencies the river Tarim makes by comparison much the smallest contribution of disintegrated material to the volume of sand. The area covered by sands in the desert of Takla Makan proper is estimated at nearly 116,000 sq. m., and the area covered by them in the desert of Cherchen at nearly 143,000 sq. m.

[1] Sven Hedin, *op. cit.* i. 364.
[2] *Op. cit.* ii. 448.

Vegetation and animal life are extremely scarce. The former is practically confined to various steppe plants, *kamish* (reeds), tamarisks (almost invariably growing on root-mounds), and poplars. The animals are hares, rats and one or two other rodents, foxes, and in a few places the wild camel.

The climate is one of extremes. At Merket on the W. verge of the desert of Takla Makan proper the winters are cold, though the snowfall is small, while the summers are hot. In the desert of Cherchen a temperature of −22° F. has been observed in the depth of winter, and there snow sometimes falls heavily. During the sand-storms which sweep over the region in spring, the thermometer drops as much as 10° or 12° F. below zero. On the other hand, a temperature as high as 86° has been recorded in the end of April (cf. GOBI). It is only in winter that this appalling desert can be crossed with any degree of safety. It is destitute of water, but in winter it is possible to transport ice on the backs of camels. Sometimes for days together the desert is enveloped in an impenetrable dust-haze, which chokes and smothers every living creature. In the second half of the 13th century Marco Polo left a vivid description of this desert and related legends associated with it (see the edition of his travels in English by Sir H. Yule, ed. 1903). The fullest account by a modern writer is that given by Sven Hedin in his *Scientific Results of a Journey in Central Asia*, 1899–1902 (Stockholm, vols. i. and ii. 1905–6); see also his *Through Asia* (London, 1898), vol. i. For archaeology, see TURKESTAN. (J. T. BE.)

TALAING, more accurately called Môn, the name given to the remnant of the Peguan race, which for long strove with the Burmans for the ascendancy in what is now Burma. In the middle of the 18th century the Peguans were masters of the country from the Gulf of Martaban to far to the north of Mandalay. Now, however, the Talaing population is practically confined to the Tenasserim and Pegu divisions of Lower Burma, and even there it seems to be dying out. According to the census of 1901 they numbered only 321,898 persons, of whom 154,480 spoke the Talaing language. The Talaings are, historically, the most important representatives in Burma of the Môn-Annam linguistic family, who have left tokens of their presence from the Khasia Hills in Assam to the Gulf of Siam. The origin of the name Talaing is disputed, but it is most commonly believed to be a term of reproach, meaning "downtrodden," given by the conquering Burmans. The people call themselves Mons. They are lighter in complexion and more sturdily built than the Burmans and the face is rounder.

TALAR, the architectural term given to the throne of the Persian monarchs which is carved on the rock-cut tomb of Darius at Nakst in Rustan, near Persepolis, and above the portico which was copied from his palace.

TALAVERA DE LA REINA, a town of central Spain, in the province of Toledo; on the right bank of the river Tagus, and on the Madrid-Cáceres railway. Pop. (1900) 10,580. Talavera is of great antiquity, the Caesobriga of the Romans. Portions of the triple wall which surrounded it remain standing, and the Arco de San Pedro is one of its Roman gates restored. Among the ancient buildings are the Torres Albarranas, built by the Moors in the 10th century, the Gothic collegiate church, and three secularized convents, one of which dates from the 14th century, but has twice been partially restored, and is now a factory. The bridge of thirty-five arches across the Tagus dates from the 15th century. Talavera "of the queen" was so named because, from the reign of Alphonso XI. (1312–50), it was the property of the queens of Castile.

For the operations which culminated in the famous battle of Talavera, between the English and the French, and those which followed that engagement, see PENINSULAR WAR. Sir Arthur Wellesley (afterwards Duke of Wellington), the British commander, acting in co-operation with Lieutenant-General Cuesta's Spanish army, took position on the 27th of July 1809 on the Upper Tagus, protected by his advanced guard. His line, facing due east, ran north from the right bank of the river to a ridge running parallel to the Tagus, beyond which ridge, also parallel to the river, lay the Sierra de Montalban. Cuesta's men with their right flank resting on the river held Talavera itself and the close country to the northward of it; Wellesley's right connected with Cuesta's left, and his line stretched away northwards to the ridge mentioned above. The Sierra was not, on the first day, occupied, and even on the inner ridge itself the division of General (afterwards Lord) Hill was from some misunderstanding very late in taking up its position. The whole front was covered by a rivulet running from the ridge to the Tagus. The battle was begun by the attack of two French divisions on the British advanced guard, which retired into the main position with severe loss and in some disorder. Marshal Victor's forces followed them up sharply, and soon came upon Wellesley's line of battle. For some time the possession of the ridge (owing to the delay of Hill's Division) was doubtful, and Rufane Donkin's brigade had a severe struggle, but in the end the arrival of Hill's troops secured this all-important point for the Allied left. Meanwhile the Spaniards (though there was at first a temporary panic amongst them) and the right divisions of the British repulsed an attack in the plain, and the day closed with the armies facing each other along the rivulet and on the ridge. The losses had been heavy on both sides. Early on the 28th the battle was renewed by a furious attack on Hill's troops, whose left was now prolonged to the Sierra by the Allied cavalry and a division borrowed from Cuesta. King Joseph Bonaparte and Jourdan his chief of staff, who were present, were averse from fighting on this present ground, wishing to wait for Soult, whom they expected to come in on Wellesley's rear, and it was only after long discussion that the king gave a reluctant assent to Victor's plan of attack. That Marshal's divisions once more tried to oust Hill from the ridge, and once more failed before the steady volleys of the British line and the charge of the cavalry posted in this quarter (though, owing perhaps to defective ground-scouting, this nearly ended in disaster). At the same time General Sebastiani's 4th corps, after a heavy bombardment, assaulted the Allied centre in the plain. Here the British and Spanish battalions held their own firmly, and a counter attack by General Mackenzie's division hurled back the French in disorder. Yet another attack followed these failures, and came very near to achieving a great success. This time Lapisse's division of Victor's corps attacked the Allies' left centre, composed of the British Guards. The French columns were again checked by the British line, but here the counter-stroke, unlike Mackenzie's, was carried too far, and the troops in the ardour of incautious pursuit were very severely handled and pushed back to the position by the French reserves; when Wellesley decided the day by a counter attack with the 48th regiment, made with great intrepidity and steadiness. The Guards, with splendid discipline, resumed their positions, and eventually the French, with their leader Lapisse mortally wounded, fell back. Failure all along the line and heavy losses left King Joseph no alternative but to retire towards Madrid. The French lost 7268 men out of 46,138 present, the British 5363 out of 20,641; the Spanish losses were officially returned at 1201 out of some 36,000 present.

TALBOT (Family). Apart from its achievements, this is one of the few families in the English aristocracy which traces alike its descent and its surname from the Norman conquerors of England; and it may be said that there has hardly been a time during more than seven centuries in which the Talbots have not been of considerable account in public life. Yet in some periods they appear rather as a potential influence, while at certain marked epochs they stand out among the most prominent actors in English history. The name of Richard Talbot occurs in Domesday Book as the holder of nine hides of land in Bedfordshire under Walter Giffard. There is no evidence that he came over to England with the Conqueror himself; and, as he did not hold of the king *in capite*, it is clear that he was not a leader. Talbot being a personal nickname and not derived from a place, those who bore it were not of necessity connected, and the early pedigree is obscure. But a Geoffrey Talbot took part with the empress Maud against King Stephen; and a Hugh Talbot held the castle of Plessis against Henry I. for Hugh de Gournay, and afterwards became a monk at Beaubec in Normandy. Richard Talbot, with whom the proved pedigree begins, obtained from Henry II. on his accession the lordship of Linton in Herefordshire, and from Richard I. the custody of Ludlow Castle; and his descendants for some generations appear to have been wardens of various castles on the borders of Wales, and intermarried with the great families of this region. Under Edward II. a Gilbert Talbot was head of the house, and invaded Scotland in the king's company, but afterwards took part with Thomas of Lancaster against the king. He, however, was pardoned, and obtained from Edward III. a confirmation of the grant of the manor of Linton and other lands, being also summoned to parliament as a baron (1331).

His son Richard, who had married a daughter and co-heiress of John Comyn of Badenoch, laid claim to certain lands in Scotland in her right, and, when restrained from entering that country by land (Edward III. having then made an alliance with King David), he joined in a successful expedition which invaded it by sea in the interests of Edward Baliol. Three years later he was taken prisoner in Scotland, and redeemed for 2000 marks, after which the king made him governor of Berwick. He took part also in Edward's wars against France, as did likewise his son Gilbert, who succeeded him. His wife had brought him the noble seat of Goodrich Castle on the Wye, and at this time the family possessed lands in the counties of Oxford, Gloucester, Hereford and Kent. Gilbert's son Richard added to this inheritance by marrying the heiress of Lord Strange of Blackmere, and himself became under Richard II. one of the heirs of the earl of Pembroke, thus adding to his estates, lands in Berkshire, Wilts, Salop and Essex. Another Gilbert Talbot, grandson of the last, claimed to carry the great spurs at the coronation of Henry V., and had a commission to receive the submission of Owen Glendower and his adherents. He also distinguished himself in the invasion of Normandy. He was twice married, his second wife being a Portuguese lady, but he left no male issue, and was succeeded by his brother John.

Hitherto the head of the house had borne the name of Lord Talbot; but this John, after obtaining by marriage the title of Lord Furnival, was for his distinguished actions created earl of Shrewsbury (see Shrewsbury, John Talbot, 1st earl of).

Besides his martial exploits, this John claims some attention for his family alliances. His first wife Maud, a granddaughter of Thomas, Lord Furnival, brought him the castle of Sheffield as part of her inheritance, and he was accordingly summoned to parliament in the days of Henry IV. as John Talbot of Hallamshire, otherwise Lord Furnival, more than thirty years before he was made earl of Shrewsbury. The property became a favourite residence of the family during the Tudor era; and, but for the death in 1616 of Gilbert, 7th earl of Shrewsbury, without male issue, Sheffield might have remained much longer a centre of feudal magnificence rather than of commerce and manufactures. The second wife of John, earl of Shrewsbury, was Margaret, the eldest of three daughters of Richard Beauchamp, earl of Warwick, by that earl's second wife, a daughter of Thomas, Lord Berkeley. By her he obtained a third part of the Berkeley property; and, though she did not become the mother of a line of earls, her eldest son, John Talbot, was created Viscount Lisle, and it was he who fell along with his father at the disastrous battle of Chatillon in Gascony. His son Thomas, who inherited the title of Viscount Lisle, was slain at the early age of twenty-two in a feudal contest with Lord Berkeley, arising out of a dispute as to the possession of Berkeley castle, on the 20th of March 1470; and the title was afterwards conferred on Edward Grey, the husband of one of his two sisters.

John, the second earl of Shrewsbury, was the 1st earl's son by his first wife. He had been knighted at Leicester in 1426 along with the infant king Henry VI., had served in the wars of France, and been made chancellor of Ireland during his father's lifetime, when he was only Lord Talbot. Afterwards he was made lord high treasurer of England, and in 1459 was rewarded for his services to the house of Lancaster with a grant of 100 marks a year out of the lordship of Wakefield, forfeited by Richard, duke of York. But next year he and his brother Christopher were slain at the battle of Northampton, fighting in the cause of Henry VI. His son John succeeded him, and then his grandson George, who fought for Henry VII. at Stoke, and whom King Henry VIII. sent as his lieutenant against the rebels in the Pilgrimage of Grace. But perhaps the thing which most redounds to his credit is the humanity with which he received the fallen Cardinal Wolsey into his house at Sheffield when he was on his way up to London as a state prisoner.

Francis, the 5th earl, took a leading part in the invasions of

Scotland under Henry VIII. and Edward VI., and was one of the two peers who alone opposed the bill for abolishing the pope's jurisdiction under Elizabeth. His son George, who succeeded, was the earl to whom the custody of Mary Stuart was committed, his task being rendered all the more difficult for him by the intrigues of his second wife, Bess of Hardwick, the builder of Chatsworth, who had married three husbands before her union with him. Two sons of this last earl succeeded one another, and the title then devolved, for want of male issue, on the lineal descendants of Sir Gilbert Talbot of Grafton in Worcestershire, third son of John, the 2nd earl. But the old baronies of Talbot, Strange of Blackmere, and Furnival had passed away in 1616 to the daughters of the 7th earl, of whom the youngest married Thomas (Howard) earl of Arundel, whose descendant, the duke of Norfolk, has the valuable Furnival estates. The above Sir Gilbert had fought for Henry VII. at Bosworth, where he was severely wounded, was knighted on the field, and was throughout one of the first Tudor's most trusted councillors. He fought also at Stoke against the insurgents with Lambert Simnel, was made a knight banneret, governor of Calais, and lord chamberlain.

The 9th earl, George, descended from this Gilbert, died unmarried, and his nephew, who followed, was succeeded by his grandson Francis, chiefly memorable for his unhappy fate. His second wife, the "wanton Shrewsbury" of Pope, a daughter of the earl of Cardigan, was seduced by the duke of Buckingham, whom the outraged husband challenged to a duel. The countess, it is said, was present at the scene, and held Buckingham's horse in the disguise of a page, saw her husband killed, and then clasped her lover in her arms, receiving blood-stains upon her dress from the embrace. Charles, the 12th earl, son of this unfortunate nobleman, was raised by William III. to the dignity of a duke, but as he left no son this title died along with him in 1718, and the earldom of Shrewsbury devolved on his cousin Gilbert, a Roman Catholic priest.

From this time the direct line of Sir Gilbert Talbot of Grafton began to fail. A nephew three times succeeded to an uncle, and then the title devolved upon a cousin, who died unmarried in 1856. On the death of this cousin the descent of the title was for a short time in dispute, and the lands were claimed for Lord Edmund Howard (now Talbot), an infant son of the duke of Norfolk, under the will of the last earl; but the courts decided that, under a private act obtained by the duke of Shrewsbury shortly before his death, the title and bulk of the estates must go together, and the true successor to the earldom was found in Earl Talbot, the head of another line of the descendants of Sir Gilbert Talbot of Grafton, sprung from a second marriage of Sir Gilbert's son, Sir John Talbot of Albrighton. The head of this family in the beginning of the 18th century was a divine of some mark, William Talbot, who died bishop of Durham in 1730. His son Charles, who filled the office of lord chancellor, was created Baron Talbot of Hensol in Glamorganshire in 1733; and his son William was advanced to the dignity of Earl Talbot in 1761, to which was added Ingestre, the barony of Dynevor, with special remainder to his daughter, Lady Cecil Rice, in 1780. Then succeeded a nephew, who was created Viscount and Earl Talbot, and assumed by royal licence the surname of Chetwynd before Talbot, from his mother.

All the titles just mentioned have been united in the line of the Earl Talbot who successfully claimed the Shrewsbury title as the 18th earl, the earldom of Shrewsbury (1442) being now the oldest existing that is not merged in a higher title. The family seats (Alton Towers and Ingestre Hall) and the chief estates are in Staffordshire. The old badge of the family was a "talbot" or running hound. (J. Ga.; J. H. R.)

TALBOT, MARY ANNE (1778–1808), the "British Amazon," was born in London on the 2nd of February 1778. She believed herself to be the illegitimate child of the 1st Earl Talbot. Early in her career she eloped, in the disguise of a boy, with a captain. In 1792 she was a drummer in Flanders. In the capture of Valenciennes her lover was killed; and Mary Anne deserted and became cabin boy on a French lugger, which she asserted was captured by the British, who transferred her to the "Brunswick," where she served as a powder monkey, being wounded in Lord Howe's victory of the 1st of June 1794. For this she later received a small pension. When the wound healed she again went to sea, was captured by the French, and imprisoned for a year and a half. Her sex was not discovered until shortly afterwards she was seized by a pressgang. She finally became a household servant to Robert Kirby, a London publisher, who included an account of her adventures in his *Wonderful Museum* (1804) and in *Life and Surprising Adventures of Mary Anne Talbot* (1809). She died on the 4th of February 1808.

TALBOT, WILLIAM HENRY FOX (1800–1877), English discoverer in photography, was the only child of William Davenport Talbot, of Lacock Abbey, Wilts, and of Lady Elizabeth Fox Strangways, daughter of the 2nd earl of Ilchester. He was born on the 11th of February 1800, and was educated at Harrow and at Trinity College, Cambridge, where he gained the Porson prize in 1820, and graduated as twelfth wrangler in 1821. From 1822 to 1872 he frequently communicated papers to the Royal Society, many of them on mathematical subjects. At an early period he had begun his optical researches, which were to have such important results in connexion with photography. To the *Edinburgh Journal of Science* in 1826 he contributed a paper on "Some Experiments on Coloured Flame"; to the *Quarterly Journal of Science* in 1827 a paper on "Monochromatic Light"; and to the *Philosophical Magazine* a number of papers on chemical subjects, including one on "Chemical Changes of Colour." Before L. J. M. Daguerre exhibited in 1839 pictures taken by the sun, Talbot had obtained similar success, and as soon as Daguerre's discoveries became known communicated the results of his experiments to the Royal Society. In 1841 he made known his discovery of the calotype or talbotype process, and after the discovery of the collodion process by Frederick Scott Archer in 1851 he devised a method of instantaneous photography. For his discoveries, which are detailed in his *Pencil of Nature* (1844), he received in 1842 the Rumford medal of the Royal Society. While engaged in his scientific researches he devoted much time to archaeology. He published *Hermes, or Classical and Antiquarian Researches* (1838–39), and *Illustrations of the Antiquity of the Book of Genesis* (1839). With Sir Henry Rawlinson and Dr Edward Hincks he shares the honour of having been one of the first decipherers of the cuneiform inscriptions of Nineveh. He was also the author of *English Etymologies* (1846). He died at Lacock Abbey on the 17th of September 1877.

TALBOT OF HENSOL, CHARLES TALBOT, 1st Baron (1685–1737), lord chancellor of England, was the eldest son of William Talbot, bishop of Durham, a descendant of the 1st earl of Shrewsbury. He was educated at Eton and Oriel College, Oxford, and became a fellow of All Souls College in 1704. He was called to the bar in 1711, and in 1717 was appointed solicitor-general to the prince of Wales. Having been elected a member of the House of Commons in 1720, he became solicitor-general in 1726, and in 1733 he was made lord chancellor and raised to the peerage with the title of Baron Talbot of Hensol. Talbot proved himself an equity judge of exceptional capacity and of the highest character during the three years of his occupancy of the Woolsack. He died on the 14th of February 1737. Among his contemporaries Talbot enjoyed the reputation of a wit; he was a patron of the poet Thomson, who in *The Seasons* commemorated a son of his to whom he acted as tutor; and Butler dedicated his famous *Analogy* to the lord chancellor. The title assumed by Talbot was derived from Hensol in Glamorganshire, which came to him through his wife.

See Lord Campbell, *Lives of the Lord Chancellors and Keepers of the Great Seal* (8 vols. London, 1845–69); Edward Foss, *The Judges of England* (9 vols. London, 1848–64); Lord Hervey, *Memoirs of the Reign of George II.* (2 vols. London, 1848); G. E. C., *Complete Peerage*, vol. vii. (London, 1896).

TALC, a mineral which in its compact forms is known as *steatite*, or *soapstone*. It was probably the μαγνῆτις λίθος of Theophrastus, described as a stone of silvery lustre, easily cut. The word talc, sometimes written talk, is said to come from the Arabic *talq*, and not to be connected, as has been fancifully suggested, with the Swedish *tälja*, "to cut." Talc and mica were confused by the older writers, and even at the present day mica is sometimes known in trade as talc; whilst the term was formerly applied also to foliated gypsum.

Talc is found occasionally in small hexagonal and rhombic plates, with perfect basal cleavage, and they are supposed to be monoclinic. Talc often occurs in foliated masses, sometimes with a curved surface, readily separating into thin very flexible, non-elastic laminae. The plates give a six-rayed percussion-figure. Talc has a hardness of only about 1, and a specific gravity of from 2·6 to 2·8. Its extreme softness and its greasy feel are characteristic. The lustre on the cleavage face is pearly, or sometimes silvery, and one of the old names of the mineral was *stella terrae*, while German writers sometimes called it *Katzensilber*. The colour is white, grey, yellow or frequently green. The mineral has strong birefringence and a small optic axial angle.

Talc is a magnesium silicate $H_2Mg_3Si_4O_{12}$. It is generally regarded as a hydrous silicate, but the water is expelled only at a very strong heat, and may therefore be regarded as basic. By the action of heat the hardness of the mineral is greatly increased. Pseudomorphs are known after actinolite, pyroxene, &c., and the mineral has probably been generally formed by the alteration of ferro-magnesian silicates. Talc occurs chiefly in crystalline schists, usually associated with chlorite, serpentine and dolomite. Fine examples of apple-green colour are found at Mount Greiner, in the Zillerthal, Tirol. Talc-schist is a foliated rock composed chiefly of talc, generally associated with quartz and felspar; but all soapy schists are not necessarily talcose. The pearly micaceous constituent of the Alpine protogine is a muscovite.

The "steatites" of Pliny was a stone resembling fat, but otherwise undescribed. Being easily cut, steatite has always been a favourite material with the carver: it was used for Egyptian scarabs and other amulets, which were usually coated with a blue vitreous glaze; and it was employed for Assyrian cylinder-seals and for other ancient signets. By the Chinese steatite is largely used for ornamental carvings, but many of their "soapstone" figures are wrought in a compact pyrophyllite (*q.v.*), which is essentially different from talc. The name agalmatolite is often applied to the material of these figures, and was suggested by M. H. Klaproth from the Greek ἄγαλμα, "an image." Pagodite is an old name for Chinese figure-stone. Ancient steatite carvings are found among the ruins of Rhodesia.

Steatite is usually a white, grey, greenish or brown substance, occurring in veins or nodular masses or in lenticular bedded deposits. Pseudomorphs after quartz and dolomite occur near Wunsiedel in Bavaria. In some cases it is a product of the alteration of pyroxenic rocks, and the commercial mineral may be very impure. The ease with which steatite may be worked, coupled with its power of resisting heat, has led to its employment for vessels for household use, whence it is called "potstone"—the *lapis ollaris* of old writers. Among the uses of steatite may be mentioned its employment, especially in America, for sinks, stoves, firebricks, foot-warmers, tips for gas-burners and electric switchboards: when ground it is used as a filler for paper, for leather-dressing, for covering steam-pipes, as an ingredient in soap, for toilet-powder, for certain paints and as a lubricant. A fine granular steatite is used by tailors for marking cloth under the name of "French chalk" or "Spanish chalk." Slate pencils are made of steatite and pyrophyllite; and in Burma steatite pencils are used for writing on black paper. In the oxyhydrogen flame, steatite has been fused and drawn out into threads, like quartz-fibres.

Steatite and talc-schists are widely distributed, and have occasionally been used as building stones. When first raised the stone is soft, but hardens on exposure. Soapstone from Gudbrandsdal is used in the cathedral of Trondhjem in Norway. Veins of steatite occur in the serpentine of the Lizard district in Cornwall, and the mineral was used under the name of soap rock in the manufacture of the old Worcester porcelain. Among localities of steatite in the British Isles mention may be made of Crohy Head and Gartan near Letterkenny in co. Donegal, Ireland; the Shetland isles, the Hebrides (Harris) and Shiness in Sutherland. In North America the distribution of the mineral is very extensive; localities of economic importance are near Gouverneur and elsewhere in St Lawrence co., New York; at Francestown in New Hampshire; Stockbridge, Windsor co., Vermont; Lynnfield, Massachusetts; near Lafayette, Pennsylvania; Albemarle, Amelia, Buckingham, Fairfax and Fluvanna cos., Virginia; Cherokee, Moore and Swain cos., North Carolina; and in Murray co., Georgia.

A fibrous steatite from New York state, used in the manufacture of paper, is known as agalite. Rensselaerite is a wax-like talcose substance, passing into serpentine, from St Lawrence co., New York, named by E. Emmons in 1837 after S. Van Rensselaer, of Albany, N.Y. Beaconite is an asbestiform talc from Michigan, named by L. W. Hubbard. The term pyrallolite was given by Nils G. Nordenskiöld to a mineral from Finland, which appears to be talc pseudomorphous after pyroxene. Talcoid was K. F. Naumann's name for a white lamellar mineral from near Pressnitz in Bohemia. A blue earthy mineral from near Silver City, New Mexico, known locally as "native ultramarine," is a magnesium silicate.

See "Talc and Soapstone" in vol. ii. of *Mineral Resources of the U.S.* (Washington, 1909), and J. H. Pratt, "Economic Papers," No. 3 of Geol. Surv. of N. Carolina (1900); also E. W. Parker in 19th *Report* of U.S. Geol. Surv. (1898); C. H. Smyth, junior, *The Fibrous Talc Industry of St Lawrence Co.*, N.Y., in "Mineral Industry," vol. ix., for 1900; and G. P. Merrill's *Non-metallic Minerals* (New York, 1904). (F. W. R.*)

TALCA, a province of Chile, bounded N. by Curico, E. by Argentina, S. by Linares and Maule, and W. by the Pacific. Area 3840 sq. m. Pop. (1895) 128,961. In the E. the Andean slopes cover a considerable part of its territory, and in the W. another large area is covered by the coast range. Between these is the central valley of Chile in which the population and industries of the province are chiefly concentrated. The mountainous parts are well wooded. The intermediate plain, which is rolling and slopes gently to the S., is fertile and devoted to wheat and stock. The capital of the province is Talca (pop. 1895, 33,232; 1902 estimated 42,766), on the Rio Claro, a tributary of the Maule, 156 m. by rail S. of Santiago. It is one of the most important provincial towns and commercial centres of central Chile. There are woollen factories, especially for the universally worn "poncho." Talca has railway connexion with Santiago on the N., with Concepción on the S., and with Constitución at the mouth of the Maule.

TALCAHUANO, or TALCAGUANO, a seaport of the province of Concepción, Chile, on the bay of Concepción, 8 m. N.W. of the city and port of that name. Pop. (1895) 10,431; (1902, estimated) 13,499. It is sheltered by the island of Quiriquina. It has the best harbour on the Pacific coast of South America, and is one of the most important ports of southern Chile, being connected by rail with Concepción, Santiago and southern Chile. Its foreign trade is large and steadily increasing. The Chilean government has established its chief naval depot here.

TALE (O.Eng. *talu*, number, account, story; the word is common to many Teutonic languages; cf. Ger. *Zahl*, number, *Erzählung*, narrative, Du. *taal*, speech, language), a general term, in the usual acceptance of the word, for fictitious narratives, long or short, ancient or modern (see NOVEL). In this article "tale" is used in a stricter sense, as equivalent to the German "Volks-märchen" or the French "conte populaire." Thus understood, popular tales mean the stories handed down by oral tradition from an unknown antiquity, among savage and civilized peoples. So understood, popular tales are a subject in mythology, and indeed in the general study of the development of man, of which the full interest and importance was long unrecognized. Popular tales won their way into literature, it is true, at a very distant period. The Homeric epics, especially the *Odyssey*, contain adventures (those, for example, of the Cyclops and the husband who returns in disguise) which are manifestly parts of the general human stock of popular narrative. Other examples are found in the *Rigveda*, and in the myths which were handled by the Greek dramatists. Collections of popular tales, more or less subjected to conscious literary treatment, are found in Sanskrit, as in the work of Somadeva, whose *Kathā Sarit Sāgara*, or "Ocean of the Streams of Story," has been translated by Mr Tawney (Calcutta, 1880). The THOUSAND

AND ONE NIGHTS (*q.v.*) are full of popular tales, and popular tales are the staple of the medieval *Gesta Romanorum*, and of the collections of Straparola and other Italian conteurs. In all these and similar gatherings the story, long circulated from mouth to mouth among the people, is handled with conscious art, and little but the general outline of plot and character of incident can be regarded as original. In the *Histories ou Contes du Temps Passé* of Perrault (Elzevir, Amsterdam, 1697; the Parisian edition is of the same date) we have one of the earliest gatherings of tales which were taken down in their nursery shape as they were told by nurses to children. This at least seems probable, though M. Alfred Maury thinks Perrault drew from literary sources. Perrault attributed the composition to his son, P. Darmancour, at that time a child, and this pretext enabled him to give his stories in a simple and almost popular guise. It seems that popular tales in many cases probably owe their origin to the desire of enforcing a moral or practical lesson. It appears that their irrational and "infantile" character—"dépourvues de raison"—is derived from their origin, if not actually among children, at least among childlike peoples, who have not arrived at "raison," that is, at the scientific and modern conception of the world and of the nature of man.

The success of Perrault's popular tales brought the genre into literary fashion, and the Comtesse d'Aulnoy invented, or in some cases adapted, "contes," which still retain a great popularity. But the precise and scientific collection of tales from the lips of the people is not much earlier than our century. The chief impulse to the study was given by the brothers Grimm. The first edition of their *Kinder- und Haus-Märchen* was published in 1812. The English reader will find a very considerable bibliography of popular tales, as known to the Grimms, in Mrs Alfred Hunt's translation, *Grimm's Household Tales, with Notes* (London, 1884). "How unique was our collection when it first appeared," they exclaim, and now merely to enumerate the books of such traditions would occupy much space. In addition to the märchen of Indo-European peoples, the Grimms became acquainted with some Malay stories, some narratives of Bechuanas, Negroes, American Indians, and Finnish, Esthonian, and Magyar stories. Thus the Grimms' knowledge of non-European märchen was extremely slight. It enabled them, however, to observe the increase of refinement "in proportion as gentler and more humane manners develop themselves," the monstrosities of Finnish and Red-Indian fancy gradually fading in the narratives of Germans and Italians. The Grimms notice that the evolution of popular narrative resembles the evolution of the art of sculpture, from the South-Sea idol to the frieze of the Parthenon, "from the strongly marked, thin, even ugly, but highly expressive forms of its earliest stages to those which possess external beauty of mould." Since the Grimms' time our knowledge of the popular tales of non-European races has been greatly enriched. We possess numbers of North-American, Brazilian, Zulu, Swahili, Eskimo, Samoan, Maori, Kaffir, Malagasy, Bushman, North African, Fiort, New Caledonian, and even Australian märchen, and can study them in comparison with the stories of Hesse, of the West Highlands of Scotland, of Scandinavia.

While the popular romances of races of all colours must be examined together, another element in this subject is not less important. It had probably been often observed before, as by Lord Fountainhall (1670), but the fact was brought out most vividly by J. G. von Hahn (*Griechische und albanesische Märchen*, Leipzig, 1864), that the popular tales of European races turn on the same incidents, and display the same succession of situations, the same characters, and the same plots, as are familiar in the ancient epic literature of Greece, India, Germany and Scandinavia. The epics are either fully-developed märchen evolved by the literary genius of poets and saga-men, or the märchen are degenerate and broken-down memories of the epics and sagas, or perhaps there may be examples of both processes. The second view,—namely, that the popular tales are, so to speak, the scattered grains of gold of which the epic is the original "pocket" or "placer,"—the belief that the märchen are the detritus of the saga,—was for a long time prevalent. But a variety of arguments enforce the opposite conclusion, namely, that the märchen are essentially earlier in character than the epic, the final form to which they have been wrought by the genius of Homer or of some other remote yet cultivated poet. If this view be accepted, the evolution of märchen and of certain myths has passed through the following stages:—

(1) The popular tale, as current among the uncultivated peoples, such as Iroquois, Zulus, Bushmen, Samoans, Eskimo, and Samoyedes. This tale will reflect the mental condition of rude peoples, and will be full of monstrous and miraculous events, with an absence of reason proper, as Perrault says, "à ceux qui n'en ont pas encore." At the same time the tale will very probably enforce some moral or practical lesson, often the sanction of a taboo, and may even appear to have been invented with this very purpose, for man is everywhere impressed with the importance of *conduct*.

(2) The same tale—or rather a series of incidents and a plot essentially the same—as it is discovered surviving in the oral traditions of the illiterate peasantry of European races. Among them the monstrous element, the ferocity of manners observed in the first stage, will be somewhat modified, but will be found most notable among the Slavonic tribes. Nowhere, even in German and Scottish märchen, is it extinct, cannibalism and cruel torture being favourite incidents.

(3) The same plots and incidents as they exist in the heroic epics and poetry of the cultivated races, such as the Homeric epics, the Greek tragedies, the Cyclic poets, the *Kalewala* of the Finns, certain hymns of the *Rigveda*, certain legends of the Brahmanas, the story of the Volsungs,—in these a local and almost historical character is given by the introduction of names of known places, and the adventures are attributed to national heroes,—Odysseus, Oedipus, Sigurd, Wainamoïnen, Jason, Pururavas, and others. The whole tone and manners are nobler and more refined in proportion as the literary workmanship is more elaborate.

This theory of the origin of popular tales in the fancy of peoples in the savage condition (see MYTHOLOGY), of their survival as märchen among the peasantry of Indo-European and other civilized races, and of their transfiguration into epics, could only be worked out after the discovery that savage and civilized popular tales are full of close resemblances. These resemblances, when only known to exist among Indo-European peoples, were explained as part of a common Aryan inheritance, and as the result of a malady of language. This system, when applied to myths in general, has already been examined (see MYTHOLOGY). According to another view, märchen everywhere resemble each other because they all arose in India, and have thence been borrowed and transmitted. For this theory consult Benfey's *Panchatantra* and M. Cosquin's *Contes de Lorraine* (Paris, 1886). In opposition to the Aryan theory, and the theory of borrowing from India, the sytem which is here advocated regards popular tales as kaleidoscopic arrangements of comparatively few situations and incidents, which again are naturally devised by the early fancy. Among these incidents may be mentioned, first, kinship and intermarriage between man and the lower animals and even inorganic phenomena. Thus a girl is wooed by a frog, pumpkin, goat, bear, or elephant, in Zulu, Scotch, Walachian, Eskimo, Ojibway, and German märchen. This incident is based on the lack of a sense of difference between man and the things in the world which is prevalent among savages (see MYTHOLOGY). Other incidents familiar in our nursery tales (such as "Cinderella" and "Puss in Boots") turn on the early belief in metamorphosis, in magic, in friendly or protecting animals (totems or beast manitous). Others depend on the early prevalence of cannibalism (compare Grimm, 47, "The Juniper Tree"). This recurs in the mad song of Gretchen in *Faust*, concerning which a distinguished student writes, "This ghost of a ballad or rhyme is my earliest remembrance, as crooned by an old East-Lothian nurse." (Compare Chambers's *Popular Rhymes of Scotland*, 1870, p. 49.) The same legend occurs among the Bechuanas, and is published by Casalis. Yet another incident springs from the taboo on certain actions between husband and wife, producing the story of Cupid and Psyche (see Lang's *Custom and Myth*, 1884, p. 64). Once more, the custom which makes the youngest child the heir is illustrated in the märchen of the success, despite the jealousy of the elders, of Cinderella, of the Zulu prince (Callaway's *Tales from the Amazulu*, pp. 64, 65), and in countless other märchen. In other cases, as in the world-wide märchen corresponding to the Jason epic, we seem in presence of an early romantic invention,—how diffused it is difficult to imagine. Moral lessons, again, are inculcated by the numerous tales which turn on the duty of kindness, or on the impossibility of evading fate as announced in prophecy. In opposition to the philological explanation of the story of Oedipus as a nature-myth, this theory of a collection of incidents illustrative of moral lessons is admirably set forth in Prof. Comparetti's *Edipo e la Mitologia Comparata* (Pisa, 1867).

On a general view, then, the stuff of popular tales is a certain number of incidents and a certain set of combinations of these incidents. Their strange and irrational character is due to their remote origin in the fancy of men in the savage condition; and their wide distribution is caused, partly perhaps by oral transmission from people to people, but more by the tendency of the early imagination to run everywhere in the same grooves. The narratives, in the ages of heroic poetry, are elevated into epic song, and in the middle ages they were even embodied in legends of the saints. This view is maintained at greater length, and with numerous illustrations, in the introduction to Mrs Hunt's translation of Grimm's *Kinder- und Haus-Märchen*, and in *Custom and Myth*, already referred to.

For savage popular tales see Theal's *Kaffir Folk Lore* (2nd ed., London, 1886); Callaway's *Nursery Tales of the Amazulu* (London, 1868); Schoolcraft's *Algic Researches;* Gill's *Myths and Tales of the South Pacific;* Petitot's *Traditions Indiennes* (1886); Shortland's *Maori Religion and Mythology* (London, 1882); the *South African Folk Lore Record;* the *Folk Lore Record* (London, 1879–85, Malagasy stories); Rink's *Tales and Traditions of the Eskimo*; Bleek's *Hottentot Tales and Fables* (London, 1864); Castrén's *Samoyedische Märchen;* Maspero's *Contes Egyptiens* (from ancient Egyptian MSS.); and Leland's *Algonquin Legends* (London, 1884). For European tales, the bibliography in the translation of Grimm already referred to may be used, and the Maisonneuve collection, *Les Littératures populaires*, may be recommended. The names of Liebrecht, Köhler, Dasent, Ralston, Nigra, Pitré, Cosquin, Afanasief, Gaidoz, Sébillot, may serve as clues through the enchanted forest of the nursery tales of Europe. Miss Coxe's *Cinderella* (Folk-Lore Society) is an excellent work on the subject, as is Sidney Hartland's *Legend of Perseus*, mainly concerned with myths of miraculous births. For Australia see Mrs Langloh Parker's *Australian Legendary Tales* (2 vols.) and Howitt's *Native Tribes of South-East Australia*. M. Sébillot has edited French tales, and Mr Dennett has given *Folk-Lore of the Fiort*. There are abundant materials and discussions in Frazer's *The Golden Bough*. (A. L.)

TALENT (Lat. *talentum*, adaptation of Gr. *τάλαντον*, balance, weight, from root *ταλ-*, to lift, as in *τλῆναι*, to bear, *τάλας*, enduring, cf. Lat. *tollere*, to lift, Skt. *tulā*, balance), the name of an ancient Greek unit of weight, the heaviest in use both for monetary purposes and for commodities (see WEIGHTS AND MEASURES). The weight itself was originally Babylonian, and derivatives were in use in Palestine, Syria and Egypt. In medieval Latin and also in many Romanic languages the word was used figuratively, of will, inclination or desire, derived from the sense of balance, but the general figurative use for natural endowments or gifts, faculty, capacity or ability, is due to the parable of the talents in Matt. xxv.

TALFOURD, SIR THOMAS NOON (1795–1854), English judge and author, the son of a brewer in good circumstances, was born on the 26th of May 1795 at Reading (not, as is sometimes stated, at Doxey, near Stafford). He received his early education at Hendon, and at the Reading grammar-school. At the age of eighteen he was sent to London to study law under Joseph Chitty, the special pleader. Early in 1821 he joined the Oxford circuit, having been called to the bar at the middle Temple in the same year. When, fourteen years later, he was created a serjeant-at-law, and when again he in 1849 succeeded Mr. Justice Coltman as judge of the court of common pleas, he attained these distinctions more perhaps for his laborious care in the conduct of cases than on account of any forensic brilliance. At the general election in 1835 he was returned for Reading. This seat he retained for close upon six years, and he was again returned in 1847. In the House of Commons he introduced an International Copyright Bill; his speech on this subject was considered the most telling made in the House during that session. The bill met with strong opposition, but Talfourd had the satisfaction of seeing it pass into law in 1842, albeit in a greatly modified form. Dickens dedicated the *Pickwick Papers* to him.

In his early years in London Talfourd was dependent—in great measure, at least—upon his literary exertions. He was at this period on the staff of the *London Magazine*, and was an occasional contributor to the *Edinburgh* and *Quarterly* reviews, the *New Monthly Magazine*, and other periodicals; while, on joining the Oxford circuit, he acted as law reporter to *The Times*. His legal writings on matters germane to literature are excellent expositions, animated by a lucid and telling, if not highly polished, style. Among the best of these are his article "On the Principle of Advocacy in the Practice of the Bar" (in the *Law Magazine*, January 1846); his *Proposed New Law of Copyright of the Highest Importance to Authors* (1838); *Three Speeches delivered in the House of Commons in Favour of an Extension of Copyright* (1840); and his famous *Speech for the Defendant in the Prosecution, the Queen* v. *Moxon, for the Publication of Shelley's Poetical Works* (1841).

But Talfourd cannot be said to have gained any position among men of letters until the production of his tragedy *Ion*, which was privately printed in 1835, and produced in the following year at Covent Garden theatre. The tragedy was also well received in America, and was reproduced at Sadler's Wells in December 1861. This dramatic poem, its author's masterpiece, turns upon the voluntary sacrifice of Ion, king of Argos, in response to the Delphic oracle, which had declared that only with the extinction of the reigning family could the prevailing pestilence incurred by the deeds of that family be removed.

Two years later, at the Haymarket theatre, *The Athenian Captive* was acted with moderate success. In 1839 *Glencoe, or the Fate of the Macdonalds*, was privately printed, and in 1840 it was produced at the Haymarket; but this home drama is inferior to his two classic plays. *The Castilian* (1853) did not excite a tenth part of the interest called forth by *Ion*. Before this he had produced various other prose writings, among them his "History of Greek Literature," in the *Encyclopaedia Metropolitana*. Talfourd died in court during the performance of his judicial duties, at Stafford, on the 13th of March 1854.

In addition to the writings above-mentioned, Talfourd was the author of *The Letters of Charles Lamb, with a Sketch of his Life* (1837); *Recollections of a First Visit to the Alps* (1841); *Vacation Rambles and Thoughts*, comprising recollections of three Continental tours in the vacations of 1841, 1842, and 1843 (2 vols., 1844); and *Final Memorials of Charles Lamb* (1849–50).

TALGARTH, a decayed market town in Breconshire, South Wales, situated on the Ennig near its junction with the Llynfi (a tributary of the Wye), with a station on the joint line of the Cambrian and Midland companies from Brecon to Three Cocks Junction (2½ m. N.N.E., but in Talgarth parish). The population of the whole parish (which measures 12,294 acres) was 1466 in 1901. The church of St Gwendoline, restored in 1873, is in Perpendicular style, with an embattled tower restored in 1898. The Baptists, Congregationalists and Calvinistic Methodists have each a chapel in the town, and there is also a Congregational church at Tredwestan, founded in 1662. About 1 m. S.W. is Trevecca, where Howel Harris, one of the founders of Welsh Methodism, was born in 1713, and where in 1752 he established a communistic religious "family" of about a hundred persons; their representatives in 1842 handed over the property to the Welsh Calvinistic Methodist connexion, who in that year opened there a theological college, and in 1874 added to it a Harris memorial chapel. In 1906 the college was removed to Aberystwyth, and the buildings are now used by the Connexion as a preparatory school for ministerial students.

The fortified station of Dinas occupies the summit of a hill about $2\frac{1}{2}$ m. S.E. of Talgarth, and commands the mountain pass to Crickhowell and the eastern part of the vale of Usk. Its castle, built on the site of an earlier British fortress, was destroyed (according to Leland) by the inhabitants to prevent its falling into the hands of Glendower. The town was in the manor of English Talgarth, there being also a manor of Welsh Talgarth, in which Welsh laws prevailed.

TALIENWAN, an open bay or roadstead on the east side of the Liaotung peninsula, Manchuria. It was leased to Russia by China in 1898 with the naval fortress of Port Arthur, from which it is distant 40 m., the lease being transferred to Japan in 1905. The Russian town of Dalny (now Tairen) was built upon the west side of the bay, known as Port Victoria. Being ice-free all the year round, it has an advantage over Niuchwang, which is frozen up for four months in the year. Niuchwang, however, lies much nearer to the great producing and consuming districts of Manchuria. Talienwan is in railway connexion with Niuchwang and Peking and via the Siberian railway with Europe. It was the rendezvous of the British fleet during the Anglo-China war of 1860, whence the names Port Arthur and Port Victoria.

TALIESSIN, the name of a late 6th century British bard, of whom practically nothing is known except the attribution to him of the collection of poems known as the *Book of Taliessin.* See the article CELT, § *Literature*, IV.

TALISMAN, a magical charm. The word is often used as a term synonymous with amulet (*q.v.*), but strictly should be applied to an inanimate object which is supposed to possess a supernatural capacity of conferring benefits or powers, an amulet being that which protects or wards off evil (see MAGIC). The most common form which the talisman took in medieval or later times was that of a disk of metal or stone engraved with astrological figures, or with magical formulae, of which *Abraxas* (*q.v.*) and *Abracadabra* (*q.v.*) are the most familiar. The word is derived through the Spanish from Arab. *ṭilsamān*, plural of *ṭilsam*, an adaptation of Gr. τέλεσμα, payment, outlay (from τελεῖν, to accomplish), used in Late Gr. of an initiation or mystery and in Med. Gr. of a charm.

TALLADEGA, a city and the couty-seat of Talladega county, Alabama, U.S.A., 35 m. E. of Birmingham. Pop. (1900) 5056 (2687 negroes); (1910) 5854. It is served by the Southern, the Louisville & Nashville and other railways. Talladega is situated in the foothills of the Blue Ridge, about 560 ft. above sea level. It is the seat of the Alabama Synodical College for Women (Presbyterian, 1903), of Talladega College (Congregational, opened 1867; chartered 1869 and 1889) for the higher education of negroes—the first college for negroes in the state, and of several institutions devoted to the care of the deaf, dumb and blind. Limestone and coal are found in the vicinity. Among the manufactures are cotton goods, cotton-seed oil, iron, hosiery, chemicals and fertilizers. There are several mineral springs near the city, and the municipal water supply is derived from a spring in the city. The electric lighting and power plant is operated by water power on Jackson Shoals. Talladega was originally an Indian village. On the 9th of November 1813, it was the scene of a decisive victory of the whites and their Indian allies, 2000 strong, led by Gen. Andrew Jackson, over 1000 " Red Sticks," or Creek Indians, who were hostile to the extension of white settlements in Indian territory.

TALLAGE (med. Lat. *tallagium*, Fr. *tailage*, from late Lat. *talare*, *taleare*, Fr. *tailler*, to cut, classical Lat. *talea*, a cutting, slip; cf. " tally " and the French *taille*, *q.v.*), a special tax in England paid by cities, boroughs and royal demesnes. The word, variously interpreted as a part " cut off " from the property taxed, or as derived from the tally (*q.v.*), first appears in the reign of Henry II. as a synonym for the *auxilium burgi*, which was an occasional payment exacted by king and barons over and above the annual *firma burgi* from burgage tenants, since all boroughs after the Norman Conquest came to be regarded as in some lord's demesne. The tax displaced the Danegeld so far as the towns and demesne lands of the Crown were concerned in the second half of the 12th century, and gradually the barons were deprived of the right of tallaging their respective demesnes without royal authorization. The imposition of tallage continued under the immediate successors of Henry II.; the barons failed to secure its prohibition or even limitation at Runnymede, and Henry III. levied it frequently. The amount to be paid was determined during this time by officials of the exchequer in special fiscal circuits through separate negotiations with the various tax-paying communities, the towns usually raising their quota by means of a capitation or poll tax. Its imposition practically ceased by 1283 in favour of a general grant made in parliament, and the king's retention of tallage seemed particularly unnecessary and illogical after burgesses were summoned to parliament. The opinion used to be held that tallage was forbidden by the *Confirmatio cartarum*, but the Latin version of that document which bears the title *De tallagio non concedendo*, although cited as a statute in the preamble to the Petition of Right in 1627 and in a judicial decision of 1637, was merely a chronicler's summary of the purposes of the official French document, which did not mention tallage by name. After 1297, however, there were only three levies of the tax: one by Edward I. in 1304; again in 1312 by Edward II. despite the protests of London and Bristol; and finally in 1332, when Edward III. encountered such opposition from parliament that he withdrew the commissions and accepted in its place a grant of a tenth-and-fifteenth. The last time that the king granted leave to the barons to tallage their demesnes was in 1305. The second statute of 1340 formally enacted that the nation should thenceforth not " make any common aid or sustain charge," including tallage, without consent of parliament.

See William Stubbs, *Constitutional History of England*, vol. i. sect. 161, vol. ii. sect. 275; D. J. Medley, *English Constitutional History*, 3rd ed. (London, 1902); Pollock and Maitland, *History of English Law*, vol. i., 2nd ed.; S. J. Low and F. S. Pulling, *Dictionary of English History.*

TALLAHASSEE, the capital of Florida, U.S.A., and the county seat of Leon county, in the W. part of the state, about 40 m. E. of the Apalachicola river and 20 m. from the Gulf of Mexico, about midway by railway between Jacksonville and Pensacola. Pop. (1900) 2981 (1755 negroes); (1910) 5018; in 1900 the population of the county was 19,887, of whom 16,000 were negroes. Tallahassee is served by the Seaboard Air Line and the Georgia, Florida & Alabama railways. The city is finely situated on a hill, about 300 ft. above sea-level, and the streets are wide and well-shaded. The principal buildings are the State Capitol, Grecian in architecture, the Federal Building, and the County Court House. In the Episcopal cemetery two monuments mark the graves of Charles Louis Napoléon Achille Murat (1801–1847), the eldest son of Joachim Murat, and of his wife Catherine (1803–1867), the daughter of Col. Bird C. Willis of Virginia and a grand-niece of George Washington.[1] Tallahassee is the seat of the Florida Female College, co-ordinate with the State University for men, and the State Normal and Industrial School (for negroes), an agricultural and mechanical college. About 17 m. S. of Tallahassee, in Wakulla county, is the Wakulla Spring, about 106 ft. deep, one of the largest of the remarkable springs of Florida.

Tallahassee's name is of Seminole origin, and means, it is said, " tribal land." During a war with the Apalachee Indians in 1638 the Spaniards, according to tradition, fortified a hill W. of the city, where the Fort St Luis Place, a plantation

[1] Murat settled here about 1821, became a naturalized American citizen, relinquishing his claim to the crown of Naples, and lived here for much of the time until his death, holding successively the office of alderman, mayor and postmaster of the city, and devoting some of his leisure to the preparation of three books, describing political and social conditions in America, the last of which, *Exposition des principes du gouvernement républicain tel qu'il a été perfectionné en Amérique* (1838), was translated into many languages and was very popular in Europe. After his death his wife lived in what is still known as the Murat Homestead, about 2 m. W. of Tallahassee, and after the American Civil War she received an annuity of 30,000 francs from Napoleon III.

mansion, now stands. About 1818 most of the Indians were expelled from the vicinity, and a settlement was made by the whites. In 1824 Tallahassee, then virtually uninhabited, was formally chosen by the United States Government as the capital of the Territory of Florida, and it continued as the capital after the admission of Florida into the Union as a state in 1845. It was a residential centre for well-to-do planters before the Civil War, and Bellair, 6 m. S., now in ruins, was a fashionable pleasure resort. On the 10th of January 1861 a state convention adopted at Tallahassee an Ordinance of Secession.

TALLBOY (partly a translation and partly a corruption of the French *hautbois*), a double chest of drawers. Whereas the chest of drawers in its familiar form (sometimes in the 18th century called a "lowboy") contains three long and two short drawers, the tallboy has five, six, or seven long drawers, and two short ones. It is a very late 17th-century development of the smaller chest. The early examples are of walnut, but by far the largest proportion of the many that have survived are of mahogany, that being the wood most frequently employed in the 18th century for the construction of furniture, especially the more massive pieces. Occasionally the walnut at the beginning of the vogue of the tallboy was inlaid, just as satin-wood varieties were inlaid, depending for relief upon carved cornice-mouldings or gadrooning, and upon handsome brass handles and escutcheons. The tallboy was the wardrobe of the 18th century, but it eventually gave place to the modern type of wardrobe, which, with its sliding drawers, was speedily found to be not only as capacious as its predecessor but more convenient of access. The topmost drawers of the tallboy could only be reached by the use of bed steps, and the disappearance of high beds and the consequent disuse of steps exercised a certain influence in displacing a characteristic piece of furniture which was popular for at least a century.

TALLEMANT, GÉDÉON, SIEUR DES RÉAUX (1619–1692), French author, was born at La Rochelle on the 7th of November 1619. He belonged to a wealthy middle-class family of Huguenot persuasion; the name des Réaux he derived from a small property purchased by him in 1650. When he was about eighteen years of age he was sent to Italy with his brother François, abbé Tallemant. On his return to Paris, Tallemant took his degrees in civil and canonical law, and his father secured for him the position of *conseiller au parlement*. The profession was distasteful to him, and he decided to ensure himself a competence by marriage with his cousin Élisabeth de Rambouillet. His half-brother had married a d'Angennes, and this connexion secured for Tallemant an introduction to the Hôtel de Rambouillet. Madame de Rambouillet was no admirer of Louis XIII., and she gratified Tallemant's curiosity with stories of the reigns of Henry IV. and Louis XIII. of real historical value. But the society of the Hôtel de Rambouillet itself opened a field for his acute and somewhat malicious observation. In the *Historiettes* he gives finished portraits of Voiture, Balzac, Malherbe, Chapelain, Valentin Conrart and many others; Blaise Pascal and Jean de la Fontaine appear in his pages; and he chronicles the scandals of which Ninon de l'Enclos and Angélique Paulet were centres. They are invaluable for the literary history of the time. It has been said that the malicious intention of his work may be partly attributed to his bourgeois extraction and that the consequent slights he received are avenged in his pages, but independent testimony has established the substantial correctness of his statements. In 1685 he was converted to Catholicism. It seems that the change was not entirely disinterested, for Tallemant, who had suffered considerable pecuniary losses, soon after received a pension of 2000 livres. He died in Paris on the 6th of November 1692.

Des Réaux was a poet of some merit and contributed to the *Guirlande de Julie*, but it is by his *Historiettes* that he is remembered. The work remained in manuscript until it was edited in 1834–6 by MM. de Châteaugiron, Jules Taschereau and L. J. N. de Monmerqué, with a notice on Tallemant by Monmerqué. A third edition (6 vols. 1872) contains a notice by Paulin Paris. Tallemant had begun *Mémoires pour la régence d'Anne d'Autriche*, but the manuscript has not been found.

TALLEYRAND-PÉRIGORD, CHARLES MAURICE DE (1754–1838), French diplomatist and statesman, was born at Paris on the 13th of February 1754, though some accounts give the date as the 2nd of February. His father was Lieutenant-General Charles Daniel de Talleyrand-Périgord, and his mother was Alexandrine (*née*) de Damas Antigny. His parents, descended from ancient and powerful families, were in constant attendance at the court of Louis XV., and (as was generally the case then in their class) neglected the child. In his third or fourth year, while under the care of a nurse in Paris, he fell from a chest of drawers and injured his foot for life. This accident darkened his prospects; for though by the death of his elder brother he should have represented the family and entered the army, yet he forfeited the rights of primogeniture, and the profession of arms was thenceforth closed to him. Entrusted to the care of his grandmother at Chalais in Périgord, he there received the only kind treatment which he experienced in his early life, and was ever grateful for it. He was removed at the age of eight to the Collège d'Harcourt at Paris (now the Lycée St Louis), where his rich intellectual gifts enabled him to make good by private study the defects of the training there imparted. At the age of twelve he fell ill of smallpox, but his parents showed little or no interest in his recovery. Destined for the church by the family council which deprived him of his birthright, he was sent when about thirteen years of age to St Sulpice, where he conceived a dislike of the doctrines and discipline thrust upon him. After a visit to his uncle, the archbishop of Reims, he returned to St Sulpice to finish his preliminary training for the church, but in his spare time he read the works of Montesquieu, Voltaire, and other writers who were beginning to undermine the authority of the *ancien régime*, both in church and state. As subdeacon he witnessed the coronation of Louis XVI. at Reims, but he did not take priest's orders until four years later. Recent researches into his early life discredit most of the stories that have been told respecting his profligacy and his contempt for the claims of the church; and it is admitted that, while rejecting her authority in the sphere of dogma and intellect, he observed the proprieties of life (gambling being then scarcely looked on as a vice) and respected the outward observances of religion.

During his life at Paris he had opportunities of mixing in the circles of the philosophers and of others who frequented the salon of Madame de Genlis, and he there formed those ideas in favour of political and social reform which he retained through life. After taking his licentiate in theology in March 1778, he gave little more attention to theological studies. Nevertheless the acuteness of his powers, added no doubt to his social position, gained for him in the year 1780 the position of agent-general of the clergy of France, in which capacity he had to perform important administrative duties respecting the relations of the clergy to the civil power. The growing claims of the state on the exchequer of the clergy made his duties responsible, his colleague as agent-general being of little use. At the extraordinary assembly of the clergy in 1782 he made various proposals, by one of which he sought, though in vain, to redress the most glaring grievances of the underpaid *curés*. Though the excellence of his work as agent-general in the years 1780–86 was fully acknowledged, and earned him a special gift of 31,000 livres, yet he did not gain a bishopric until the beginning of the year 1789, probably because the king disliked him as a freethinker. He now became bishop of Autun, with a stipend of 22,000 livres, and was installed on the 15th of March.

The first rumblings of the revolutionary storm were making themselves heard. The elections for the States General were soon to take place; and the first important act of the new bishop was to draw up a manifesto or programme of the reforms which he desired to see carried out by the States General of France. It comprised the following items: the formation of a constitution which would strengthen the monarchy by calling to it the support of the whole nation, the drafting of a scheme of local self-government on democratic lines, the reform of the administration of justice and of the criminal law, and the abolition of the most burdensome of feudal and class privileges. This programme was adopted by the clergy of his diocese as their *cahier*, or book of instructions to their representative at the States General, namely Talleyrand himself.

His influence in the estate of the clergy, however, was cast against the union of the three estates in a single assembly, and he voted in the minority of his order which in the middle of June opposed the merging of the clergy in the National Assembly. The folly of the court, and the weakness of Louis XVI. at that crisis, probably convinced him that the cause of moderate reform and the framing of a bicameral constitution on the model of that of England were hopeless. Thereafter he inclined more and more to the democratic side, though for the present he concerned himself mainly with financial questions. In the middle of July he was chosen as one of the committee to prepare a draft of a constitution; and in the session of the Assembly which Mirabeau termed the *orgie* of the abolition of privileges (4th of August) he intervened in favour of discrimination and justice. On the 10th of October, that is, four days after the insurrection of women and the transference of the king and court to Paris, he proposed to the Assembly the confiscation of the lands of the church to the service of the nation, but on terms rather less rigorous than those in which Mirabeau (*q.v.*) carried the proposal into effect on the 2nd of November. He identified himself in general with the Left of the Assembly, and supported the proposed departmental system which replaced the old provincial system early in 1790. At the federation festival of the 14th of July 1790 (the "Feast of Pikes") he officiated at the altar reared in the middle of the Champ de Mars. This was his last public celebration of mass. For a brilliantly satirical but not wholly fair reference to the part then played by Talleyrand, the reader should consult Carlyle's *French Revolution*, vol. ii., bk. i., ch. 12. The course of events harmonized with the anticlerical views of Talleyrand, and he gradually loosened the ties that bound him to the church. He took little part in, though he probably sympathized with, the debates on the measure known as the Civil Constitution of the Clergy, whereby the state enforced its authority over the church to the detriment of its allegiance to the pope. When the Assembly sought to impose on its members an oath of obedience to the new decree, Talleyrand and three other bishops complied out of the thirty who had seats in the Assembly. The others, followed by the greater number of the clergy throughout France, refused, and thenceforth looked on Talleyrand as a schismatic. He did not long continue to officiate, as many of the so-called "constitutional" clergy did; for, on the 21st of January 1791, he resigned the see of Autun, and in the month of March was placed under the ban of the church by the pope.

Just before his resignation he had been elected, with Mirabeau and Sieyès, a member of the department of Paris; and in that capacity did useful work for some eighteen months in seeking to support the cause of order in the turbulent capital. Though he was often on strained terms with Mirabeau, yet his views generally coincided with those of that statesman, who is said on his death-bed (2nd of April 1791) to have communicated to him his opinions on domestic and international affairs, especially advising a close understanding with England. Talleyrand's reputation for immorality, however, was as marked as that of Mirabeau. While excelling him in suppleness and dexterity, he lacked the force of character possessed by the great "tribune of the people"; and his influence was gradually eclipsed by that of the more ardent and determined champions of democracy, the Girondins and the Jacobins. In the closing days of the first or Constituent Assembly, Talleyrand set forth (10th of September 1791) his ideas on national education. Education was to be free, and to lead up to the university. In place of dogma, the elements of religion were alone to be taught.

Debarred from election to the second National Assembly (known as the Legislative) by the self-denying ordinance passed by the "constituents," Talleyrand, at the close of 1791, sought to enter the sphere of diplomacy for which his mental qualities and his clerical training furnished him with an admirable equipment. The condition of affairs on the continent seemed to French enthusiasts to presage an attack by the other Powers on France. In reality those Powers were far more occupied with the Polish and Eastern questions than with the affairs of France; and the declaration of Pilnitz, drawn up by the sovereigns of Austria and Prussia, which appeared to threaten France with intervention, was recognized by all well-informed persons to be "a loud-sounding nothing." The French foreign minister, Delessart, believed that he would checkmate all the efforts of the *émigrés* at the continental courts provided that he could confirm Pitt in his intention of keeping England neutral. For that purpose Delessart sent Talleyrand, well known for his Anglophil tendencies, to London, but in the unofficial or semi-official capacity which was rendered necessary by the decree of the Constituent Assembly referred to above. Talleyrand arrived in London on the 24th of January 1792, and found public opinion so far friendly that he wrote off to Paris, "Believe me, a *rapprochement* with England is no chimera." Pitt received him cordially; and to Grenville the envoy stated his hope that the two free nations would enter into close and friendly relations, each guaranteeing the other in the possession of its existing territories, India and Ireland being included on the side of Britain. After some delay the British government decided to return no definite answer to this proposal, a result due, as Talleyrand thought, to the Gallophobe views of King George and of the ministers Camden and Thurlow. Talleyrand, however, was convinced that Great Britain would not intervene against France unless the latter attacked the Dutch Netherlands.

He returned to Paris on the 10th of March to persuade the foreign minister (Dumouriez now held that post) of the need of having a fully accredited ambassador at London. The ex-Marquis Chauvelin was appointed, with Talleyrand as adviser. The situation became more complex after the 19th of April, when France declared war against Austria and prepared to invade the Austrian or Belgic Netherlends. Owing to certain indiscretions of Chauvelin and the growing unpopularity of the French in England (especially after the disgraceful day of the 20th of June at the Tuileries), the mission was a failure; but Talleyrand had had some share in confirming Pitt in his policy of neutrality, even despite Prussia's overtures for an alliance against France. After Talleyrand's return to Paris early in July (probably in order to sound the situation there) matters went from bad to worse. The overthrow of the monarchy on the 10th of August and the September massacres rendered hopeless all attempts at an *entente cordiale* between the two peoples; and the provocative actions of Chauvelin, undertaken in order to curry favour with the extremists now in power at Paris, undid all the good accomplished by the tact and moderation of Talleyrand. The latter now sought to escape from France, where events were becoming intolerable; and after some unsuccessful attempts to obtain a passport to leave Paris, he succeeded on the 14th of September and landed in England on the 23rd, avowedly on private business, but still animated by the hope of averting a rupture between the two governments. In this he failed. The provocative actions of the French Convention, especially their setting aside of the rights of the Dutch over the estuary of the Scheldt, had brought the two nations to the brink of war, when the execution of Louis XVI. (21st of Jan. 1793) made it inevitable. Talleyrand was expelled from British soil and made his way to the United States. There he spent thirty months in a state of growing uneasiness and discontent with his surroundings.

The course of events after the Thermidorian reaction of July 1794 favoured his return to France. Thanks to the efforts of Daunou and others his name was removed from the list of *émigrés*, and he set sail for Europe in November 1795. Landing at Hamburg in the January following, he spent some time there in the company of his friends Madame de Genlis and Reinhard; and when party rancour continued to abate at Paris, he returned thither in September. After a time marked by some pecuniary embarrassment, he was recommended by Madame de Staël to the Director Barras for the post of minister of foreign affairs.

His claims on the attention of the Directors had been strengthened by his reading two papers before the French Institute, the first on the commercial relations between England and the United States (in the sense referred to above), and the second on the advantages to be derived from new colonies. In the latter there occurred the suggestive remarks that, whereas revolutions made men prematurely old and weary, the work of colonization tended to renew the youth of nations. France, he observed, needed the spur to practical energy which the Americans had at hand in the effort to subdue the difficulties placed in their way by nature. Similar efforts would tend to make Frenchmen forget the past, and would at the same time supply an outlet for the poor and discontented. The practical statesmanship contained in these papers raised Talleyrand in public estimation; and, thanks to the efforts above named, he gained the post of foreign minister, entering on his duties in July 1797.

Bonaparte by his victories over the Austrians in Italy and Styria had raised the French republic to heights of power never dreamed of, and now desired to impose on the emperor terms of peace, to which the Directors demurred. Talleyrand, despite the weakness of his own position (he was as yet little more than the chief clerk of his department), soon came to a good understanding with the general, and secretly expressed to him his satisfaction at the terms which the latter dictated at Campo Formio (17th of October 1797). The *coup d'état* of Fructidor (September 1797) had perpetuated the Directory and led to the exclusion of the two "moderate" members, Carnot and Barthélémy; but Talleyrand saw that power belonged really to the general who had brought about the *coup d'état* in favour of the Jacobinical Directors headed by Barras.

After the rupture of the peace negotiations with England, which resulted from the *coup d'état* of Fructidor, the policy of France became more warlike and aggressive. The occupation of Rome and of Switzerland by the French troops and the events of Bonaparte's Egyptian expedition (see NAPOLEON I.) brought about a renewal of war on the continent, but with these new developments Talleyrand had little or no connexion. His powers as minister were limited, and he regretted the extension of the area of war. Moreover, in the autumn of 1797 his reputation for political morality (never very bright) was overclouded by questionable dealings with the envoys of the United States sent to arrange a peaceful settlement of certain disputes with France. The investigations of the most recent of Talleyrand's biographers tend to show that the charges made against him of trafficking with the envoys have been overdrawn; but all his apologists admit that irregularities occurred. Talleyrand refused to clear himself of the charges made against him as his friends (especially Madame de Staël) urged him to do; and the incident probably told against his chances of admission into the Directory, which were discussed in the summer of 1798. A year later he resigned the portfolio for foreign affairs (20th of July 1799), probably because he foresaw the imminent collapse of the Directory. If so, his premonitions were correct. Their realization was assured by the return to France of the "Conqueror of the East" in October. The general and the diplomatist soon came to an understanding, and Talleyrand tactfully brought about the alliance between Bonaparte and Sieyès (*q.v.*) (then the most influential of the five Directors) which paved the way for the *coup d'état* of Brumaire (see FRENCH REVOLUTION and NAPOLEON I.).

Talleyrand's share in the actual events of the 18th, 19th Brumaire (9th, 10th of November) 1799 was limited to certain dealings with Barras on the former of those days. About midday he took to Barras a letter, penned by Roederer, requesting him to resign his post as Director. By what means Talleyrand brought him to do so, whether by persuasion, threats or bribes, is not known; but on that afternoon Barras left Paris under an escort of soldiers. With the more critical and exciting events of the 19th of Brumaire at St Cloud Talleyrand had no direct connexion; but he had made all his preparations for flight in case the blow failed. His reward for helping on the winning cause was the ministry for foreign affairs, which he held from the close of December 1799 on to the summer of 1807. In the great work of reconstruction of France now begun by the First Consul, Talleyrand played no unimportant part. His great aim was to bring about peace, both international and internal. He had a hand in the pacific overtures which Bonaparte, early in the year 1800, sent to the court of London; and, whatever may have been the motives of the First Consul in sending them, it is certain that Talleyrand regretted their failure. After the battle of Marengo an Austrian envoy had come to Paris in response to a proposal of Bonaparte, and Talleyrand persuaded him to sign terms of peace. These were indignantly repudiated at Vienna, but peace was made between the two Powers at Lunéville on the 9th of February 1801.

As regards French affairs, Talleyrand used his influence to help on the repeal of the vexatious laws against *émigrés*, non-juring priests, and the royalists of the west. He was also in full sympathy with the policy which led up to the signature of the Concordat of 1801–2 with the pope (see CONCORDAT); but it is probable that he had a hand in the questionable intrigues which accompanied the closing parts of that complex and difficult negotiation. At the end of June 1802 the pope removed Talleyrand from the ban of excommunication and allowed him to revert to the secular state. On the 10th of September 1803, owing to pressure put on him by Bonaparte, he married Madame Grand, a *divorcée* with whom he had long been living.

During the meeting of Italian notables at Lyons early in 1802 Talleyrand was serviceable in manipulating affairs in the way desired by Bonaparte, and it is known that the foreign minister suggested to them the desirability of appointing Bonaparte president of the Cisalpine Republic, which was thenceforth to be called the Italian Republic. In the negotiations for peace with England which went on at Amiens during the winter of 1801–2 Talleyrand had no direct share, these (like those at Lunéville) being transacted by Napoleon's eldest brother, Joseph Bonaparte (*q.v.*). On the other hand he helped the First Consul in assuring French supremacy in Switzerland, Italy and Germany. In Germany the indemnification of the princes who lost all their lands west of the Rhine was found by secularizing and absorbing the ecclesiastical states of the empire. This unscrupulous proceeding, known as the Secularizations (February 1803), was carried out largely on lines laid down by Bonaparte and Talleyrand; and the latter is known to have made large sums of money by trafficking with the claimants of church lands.

While helping to establish French supremacy in neighbouring states and assisting Bonaparte in securing the title of First Consul for life, Talleyrand sought all means of securing the permanent welfare of France. He worked hard to prevent the rupture of the peace of Amiens which occurred in May 1803, and he did what he could to prevent the sale of Louisiana to the United States earlier in the year. These events, as he saw, told against the best interests of France and endangered the gains which she had secured by war and diplomacy. Thereafter he strove to moderate Napoleon's ambition and to preserve the European system as far as possible. The charges of duplicity or treachery made against the foreign minister by Napoleon's apologists are in nearly all cases unfounded. This is especially so in the case of the execution of the duc d'Enghien (March 1804), which Talleyrand disapproved. The evidence against him rests on a document which is now known to have been forged. On the assumption of the imperial title by Napoleon in May 1804, Talleyrand became grand chamberlain of the empire, and received close on 500,000 francs a year.

Talleyrand had rarely succeeded in bending the will of the First Consul. He altogether failed to do so with the Emperor Napoleon. His efforts to induce his master to accord lenient terms to Austria in November 1805 were futile; and he looked on helplessly while that Power was crushed, the Holy Roman Empire swept away, and the Confederation of the Rhine set up in central Europe. In the bargainings which accompanied this last event Talleyrand is believed to have reaped a rich harvest from the German princes most nearly concerned. On the 6th of July 1806 Napoleon conferred on his minister the title of prince of Benevento, a papal fief in the Neapolitan territory.

In the negotiations with England which went on in the summer of 1806 Talleyrand had not a free hand; they came to nought, as did those with Russia which had led up to the signature of a Franco-Russian treaty at Paris by d'Oubril which was at once disavowed by the tsar. The war with Prussia and Russia was ended by the treaties of Tilsit (7th and 9th of July 1807). Talleyrand had a hand only in the later developments of these negotiations; and it has been shown that he cannot have been the means of revealing to the British government the secret arrangements made at Tilsit between France and Russia, though his private enemies, among them Fouché, have charged him with acting as traitor in this affair.

Talleyrand had long been weary of serving a master whose policy he more and more disapproved, and after the return from Tilsit to Paris he resigned office. Nevertheless Napoleon retained him in the council and took him with him to the interview with the Emperor Alexander I. at Erfurt (September 1808). There Talleyrand secretly advised that potentate not to join Napoleon in putting pressure on Austria in the way desired by the French emperor; but it is well known that Alexander was of that opinion before Talleyrand tendered the advice. Talleyrand disapproved of the Spanish policy of Napoleon which culminated at Bayonne in May 1808; and the stories to the contrary may in all probability be dismissed as idle rumours. It is also hard to believe the statement in the Talleyrand *Memoirs* that the ex-foreign minister urged Napoleon to occupy Catalonia until a maritime peace could be arranged with England. On Talleyrand now fell the disagreeable task of entertaining at his new mansion at Valençay, in Touraine, the Spanish princes virtually kidnapped at Bayonne by the emperor. They remained there until March 1814. At the close of 1808, while Napoleon was in Spain, Talleyrand entered into certain relations with his former rival Fouché (*q.v.*), which aroused the solicitude of the emperor and hastened his return to Paris. He subjected Talleyrand to violent reproaches, which the ex-minister bore with his usual ironical calm.

After the Danubian campaign of 1809 and the divorce of Josephine, Talleyrand used the influence which he still possessed in the imperial council on behalf of the choice of an Austrian consort for his master, for, like Metternich (who is said first to have mooted the proposal), he saw that this would safeguard the interests of the Habsburgs, whose influence he felt to be essential to the welfare of Europe. He continued quietly to observe the course of events during the disastrous years 1812–13; and even at the beginning of the Moscow campaign he summed up the situation in the words, "It is the beginning of the end." Early in 1814 he saw Napoleon for the last time; the emperor upbraided him with the words: "You are a coward, a traitor, a thief. You do not even believe in God. You have betrayed and deceived everybody. You would sell even your own father." Talleyrand listened unmoved, but afterwards sent in his resignation of his seat on the council. It was not accepted. He had no share in the negotiations of the congress of Châtillon in February-March 1814. On the surrender of Paris to the allies (30th of March 1814), the Emperor Alexander I. took up his abode at the hôtel Talleyrand, and there occurred the conference wherein the statesman persuaded the victorious potentate that the return of the Bourbons was the only possible solution of the French problem, and that the principle of legitimacy alone would guarantee Europe against the aggrandizement of any one state or house. As he phrased it in the Talleyrand *Memoirs:* "The house of Bourbon alone could cause France nobly to conform once more to the happy limits indicated by policy and by nature. With the house of Bourbon France ceased to be gigantic in order to be great." These arguments, reinforced by those of the royalist agent de Vitrolles, convinced the tsar; and Talleyrand, on the 1st of April, convened the French senate (only 64 members out of 140 attended), and that body pronounced that Napoleon had forfeited the crown. Ten days later the fallen emperor recognized the inevitable and signed the Act of Abdication at Fontainebleau. The next effort of Talleyrand was to screen France under the principle of legitimacy and to prevent the scheme of partition on which several of the German statesmen were bent. Thanks mainly to the support of the tsar and of England these schemes were foiled; and France emerged from her disasters with frontiers which were practically those of 1792.

At the congress of Vienna (1814–15) for the settlement of European affairs, Talleyrand, as the representative of the restored house of Bourbon in France, managed adroitly to break up the league of the Powers (framed at Chaumont in February 1814) and assisted in forming a secret alliance between England, Austria and France in order to prevent the complete absorption of Poland by Russia and of Saxony by Prussia. The new triple alliance had the effect of lessening the demands of those Powers, and of leading to the well-known territorial compromise of 1815. Everything was brought into a state of uncertainty once more by the escape of Napoleon from Elba; but the events of the Hundred Days, in which Talleyrand had no share—he remained at Vienna until the 10th of June—brought in the Bourbons once more; and Talleyrand's plea for a magnanimous treatment of France under Louis XVIII. once more prevailed in all important matters. On the 9th of July 1815 he became foreign minister and president of the council under Louis XVIII., but diplomatic and other difficulties led him to resign his appointment on the 23rd of September 1815, Louis, however, naming him high chamberlain and according him an annuity of 100,000 francs. The rest of his life calls for little notice except that at the time of the July Revolution of 1830, which unseated the elder branch of the Bourbons, he urged Louis Philippe, duke of Orleans (*q.v.*), to take the throne offered to him by popular acclaim. The new sovereign offered him the portfolio for foreign affairs; but Talleyrand signified his preference for the embassy in London. In that capacity he took an important part in the negotiations respecting the founding of the new kingdom of Belgium. In April 1834 he crowned his diplomatic career by signing the treaty which brought together as allies France, Great Britain, Spain and Portugal; and in the autumn of that year he resigned his embassy. During his last days he signed a paper signifying his reconciliation with the Roman Catholic Church and his regret for many of his early actions. The king visited his death-bed. His death, on the 17th of May 1838, called forth widespread expressions of esteem for the statesman who had rendered such great and varied services to his country. He was buried at Valençay. He had been separated from the former Madame Grand in 1815 and left no heir.

Under all the inconsistencies of Talleyrand's career there lies an aim as steadily consistent as that which inspired his contemporary, Lafayette. They both loved France and the cause of constitutional liberty. Talleyrand believed that he served those causes best by remaining in office whenever possible, and by guiding or moderating the actions of his chiefs. He lived to see the triumph of his principles; and no Frenchman of that age did so much to repair the mischief wrought by fanatics and autocrats. In the opinion of enlightened men this will mitigate the censures that must be passed on him for his laxity in matters financial. If he enriched himself, he also helped to save France from ruin at more crises than one. In private life his ease of bearing, friendliness, and, above all, his inexhaustible fund of humour and irony, won him a large circle of friends; and judges so exacting as Mmes de Staël and de Rémusat and Lord Brougham avowed their delight in his society.

By a codicil added to his will on the 17th of March 1838 Talleyrand left his memoirs and papers to the duchess of Dino and to M. de Bacourt. The latter revised them with care, and added to them other pieces emanating from Talleyrand. They were not to be published until after the lapse of thirty years from the time of Talleyrand's death. For various reasons they did not see the light until 1891. This is not the place in which to discuss so large a question as that of the genuineness of the *Mémoires*, which, indeed, is now generally admitted. There are, however, several suspicious circumstances which tell against them as documents of the first importance, notably these: first that Talleyrand is known to have destroyed many of his most important papers, and secondly that

M. de Bacourt almost certainly drew up the connected narrative which we now possess from notes which were in more or less of confusion. For this question see articles by M. Chuquet in *Rev. critique d'histoire et de littérature*, 25th of May 1891 (Paris); also articles by others in the *Rev. historique*, vols. xlviii. and xlix. (Paris); also in the *Quarterly Review*, No. 345 (London, 1891), and *Edinburgh Review*, vol. 174 (London, 1891); by P. Bailleu in the *Historische Zeitschrift*, vol. lxviii. (Munich, 1892), and by Albert Sorel in his *Lectures historiques* (pp. 70–112).

The Talleyrand *Mémoires* were edited by the duc de Broglie in 5 vols. (Paris, 1891–2). They have been translated into English by A. Hall, 5 vols. (London, 1891–2). Of his letters and despatches the following are the chief collections:—G. Pallain, *La mission de Talleyrand à Londres en* 1792 (Paris, 1889), and *Le ministère de Talleyrand sous le Directoire* (Paris, 1891); P. Bertrand, *Lettres inédites de Talleyrand à Napoléon*, 1800–9 (Paris, 1889); G. Pallain, *Talleyrand et Louis XVIII.* (Paris, 1881), and *Ambassade de Talleyrand à Londres* (1830–4), 2 vols. (Paris, 1891).

Among the biographies, or biographical notices, of Talleyrand the following are, on the whole, hostile to him: G. Touchard Lafosse, *Talleyrand, histoire politique et vie intime* (Paris, 1848); G. Michaud, *Hist. politique et privée de Talleyrand* (Paris, 1853); A. Pichot, *Souvenirs intimes sur Talleyrand* (Paris, 1870); Sainte-Beuve, "Talleyrand," in *Nouveaux lundis*, No. xii.; and Villemarest, *Talleyrand.* The estimate of him of Sir H. L. E. Bulwer Lytton in his *Historical Characters*, 2 vols. (London, 1867) and that of Lord Brougham in *Historical Sketches of Statesmen*, 3 vols. (London, 1845, new edition), are better balanced, but brief. Of recent biographies of Talleyrand the best are Lady Blennerhasset's *Talleyrand* (Berlin, 1894, Eng. translation by F. Clarke, 2 vols. London, 1894); *Talleyrand, a Biographical Study*, by Joseph McCabe (London, 1906); and Bernard de Lacombe, *La vie privée de Talleyrand* (1910). (J. Hl. R.)

TALLIEN, JEAN LAMBERT (1767–1820), French Revolutionist, was the son of the *maître d'hôtel* of the marquis de Bercy, and was born in Paris. The marquis, perceiving the boy's ability, had him well educated, and got him a place as a lawyer's clerk. Being much excited by the first events of the Revolution, he gave up his desk to enter a printer's office, and by 1791 he was overseer of the printing department of the *Moniteur*. While thus employed he conceived the idea of the *journal-affiche*, and after the arrest of the king at Varennes in June 1791 he placarded a large printed sheet on all the walls of Paris twice a week, under the title of the *Ami des Citoyens, journal fraternel*.

This enterprise, of which the expenses were defrayed by the Jacobin Club, made him well known to the revolutionary leaders; and he made himself still more conspicuous in organizing the great "Fête de la Liberté" on the 15th of April 1792, in honour of the released soldiers of Château-Vieux, with Collot d'Herbois. On the 8th of July 1792, he was the spokesman of a deputation of the section of the Place Royale which demanded from the legislative assembly the reinstatement of the mayor, Jérome Pétion, and the *procureur*, P. L. Manuel, and he was one of the most active popular leaders in the attack upon the Tuileries on the 10th of August, on which day he was appointed secretary or clerk to the revolutionary commune of Paris. In this capacity he exhibited an almost feverish activity; he perpetually appeared at the bar of the assembly on behalf of the commune; he announced the massacres of September in the prisons in terms of apology and praise; and he sent off the famous circular of the 3rd of September to the provinces, recommending them to do likewise. He had several persons imprisoned in order to save them from the fury of the mob, and protected several suspects himself. At the close of the month he resigned his post on being elected, in spite of his youth, a deputy to the Convention by the department of Seine-et-Oise, and he began his legislative career by defending the conduct of the Commune during the massacres. He took his seat upon the Mountain, and showed himself one of the most vigorous Jacobins, particularly in his defence of Marat, on the 26th of February 1793; he voted for the execution of the king, and was elected a member of the Committee of General Security on the 21st of January 1793. After a short mission in the western provinces he returned to Paris, and took an active part in the *coups d'état* of the 31st of May and the 2nd of June, which resulted in the overthrow of the Girondists. For the next few months he remained comparatively quiet, but on the 23rd of September 1793, he was sent with Claude Alexandre Ysabeau (1754–1831) on his mission to Bordeaux. This was the month in which the Terror was organized under the superintendence of the Committees of Public Safety and General Security.

Tallien showed himself one of the most vigorous of the proconsuls sent over France to establish the Terror in the provinces; though with but few adherents, he soon awed the great city into quiet. It was at this moment that the romance of Tallien's life commenced. Among his prisoners was Therèse, the divorced wife of the comte de Fontenay, and daughter of the Spanish banker, François Cabarrus, one of the most fascinating women of her time, and Tallien not only spared her life but fell in love with her. Suspected of "Moderatism" on account of this incident, especially when he was recalled to Paris, Tallien increased, in appearance, his revolutionary zeal, but Therèse abated his revolutionary ardour, and from the lives she saved by her entreaties she received the name of "Our Lady of Thermidor," after the 9th of Thermidor. Tallien was even elected president of the Convention on the 24th of March 1794. But the Terror could not be maintained at the same pitch: Robespierre began to see that he must strike at many of his own colleagues in the committees if he was to carry out his theories, and Tallien was one of the men condemned with them. They determined to strike first, and on the great day of Thermidor it was Tallien who, urged on by the danger in which his beloved lay, opened the attack upon Robespierre. The movement was successful; Robespierre and his friends were guillotined; and Tallien, as the leading Thermidorian, was elected to the Committee of Public Safety. He showed himself a vigorous Thermidorian; he was instrumental in suppressing the Revolutionary Tribunal and the Jacobin Club; he attacked J. B. Carrier and Joseph Lebon, the *représentants en mission* of Nantes and Arras; and he fought bravely against the insurgents of Prairial. In all these months he was supported by Therèse, whom he married on the 26th of December 1794, and who became the leader of the social life of Paris. His last political achievement was in July 1795, when he was present with Hoche at the destruction of the army of the *émigrés* at Quiberon, and ordered the executions which followed. After the close of the Convention Tallien's political importance came to an end, for, though he sat in the Council of Five Hundred, the moderates attacked him as terrorist, and the extreme party as a renegade. Madame Tallien also tired of him, and became the mistress of the rich banker Ouvrard. Bonaparte, however, who is said to have been introduced by him to Barras, took him to Egypt in his great expedition of June 1798, and after the capture of Cairo he edited the official journal there, the *Décade Egyptienne.* But General J. F. Menou sent him away from Egypt, and on his passage he was captured by an English cruiser and taken to London, where he had a good reception among the Whigs and was well received by Fox. On returning to France in 1802 he obtained a divorce from his wife (who in 1805 married the comte de Caraman, later prince de Chimay), and was left for some time without employment. At last, through Fouché and Talleyrand, he got the appointment of consul at Alicante, and remained there until he lost the sight of one eye from yellow fever. On returning to Paris he lived on his half-pay until 1815, when he received the favour of not being exiled like the other regicides. His latter days were spent in poverty; he had to sell his books to get bread. He died in Paris on the 16th of November 1820.

Tallien left an interesting *Discours sur les causes qui ont produit la Révolution française* (Paris, 1791, in 8vo) and a *Mémoire sur l'administration de l'Égypte à l'arrivée des Français.* See *Tallien et l'Expédition d'Égypte*, in *La Révolution Française: Revue d'histoire moderne et contemporaine*, t. iii. p. 269. On Madame Tallien see Arsène Houssaye, *Notre Dame de Thermidor* (Paris, 1866); J. Turquan, *Souveraines et grandes Dames: La citoyenne Tallien, témoignages des contemporains et documents inédits* (Paris, 1898); and Louis Gastine, *La belle Tallien* (1909).

TALLIS (Tallys, Talys, or Tallisius), **THOMAS** (*c.* 1515–1585), justly styled "the father of English cathedral music," was born about 1515. It has been conjectured that, after singing as a chorister at old Saint Paul's under Thomas Mulliner, he obtained a place among the children of the chapel royal. He is known to have become organist at Waltham abbey, where, on the dissolution of the monastery in 1540, he received, in compensation for the loss of his preferment, 20s. for wages and 20s. for reward. In the library of the British Museum there is preserved a volume of MS. treatises on music, once belonging to the abbey, on the last page of which appears his autograph, "Thomas Tallys"—the only specimen known.

Not long after his dismissal from Waltham, Tallis was appointed a gentleman of the chapel royal; and thenceforward he laboured so zealously for the advancement of his art that the English school owes more to him than to any other composer of the 16th century.

One of the earliest compositions by Tallis to which an approximate date can be assigned is the well-known *Service in the Dorian Mode*, consisting of the *Venite*, *Te Deum*, *Benedictus*, *Kyrie*, *Nicene Creed*, *Sanctus*, *Gloria in Excelsis*, *Magnificat* and *Nunc Dimittis*, for four voices, together with the *Preces*, *Responses*, *Paternoster* and *Litany*, for five, all published for the first time, in the Rev. John Barnard's *First Book of Selected Church Music*, in 1641, and reprinted, with the exception of the *Venite* and *Paternoster*, in Boyce's *Cathedral Music* in 1760.[1] That this work was composed for the purpose of supplying a pressing need, after the publication of the second prayer-book of King Edward VI. in 1552, there can be no doubt. Written in the style known among Italian composers as *lo stile famigliare*, *i.e.* in simple counterpoint of the first species, *nota contra notam*, with no attempt at learned complications of any kind—it adapts itself with equal dignity and clearness to the expression of the verbal text it is intended to illustrate, bringing out the sense of the words so plainly that the listener cannot fail to interpret them aright, while its pure rich harmonies tend far more surely to the excitement of devotional feeling than the marvellous combinations by means of which too many of Tallis's contemporaries sought to astonish their hearers, while forgetting all the loftier attributes of their art. In self-restraint the *Litany* and *Responses* bear a close analogy to the *Improperia* and other similar works of Palestrina, wherein, addressing himself to the heart rather than to the ear, the *princeps musicae* produces the most thrilling effects by means which, to the superficial critic, appear almost puerile in their simplicity, while those who are able to look beneath the surface discern in them a subtlety of style such as none but a highly cultivated musician can appreciate. Of this profound learning Tallis possessed an inexhaustible store; and it enabled him to raise the English school to a height which it had never previously attained, and which it continued to maintain until the death of its last representative, Orlando Gibbons, in 1625. Though this school is generally said to have been founded by Dr Tye, there can be no doubt that Tallis was its greatest master, and that it was indebted to him alone for the infusion of new life and vigour which prevented it from degenerating, as some of the earlier Flemish schools had done, into a mere vehicle for the display of fruitless erudition. Tallis's ingenuity far surpassed that of his most erudite contemporaries; and like every other great musician of the period, he produced occasionally works confessedly intended for no more exalted purpose than the exhibition of his stupendous skill. In his canon *Miserere nostri* (given in Hawkins's *History of Music*) the intricacy of the contrapuntal devices seems little short of miraculous; [yet the resulting harmony is smooth and normal, and only the irregular complexity of the rhythm betrays the artificiality of its structure. The famous forty-part motet, *Spem in alium*, written for eight five-part choirs, stands on a far higher plane, and the *tour de force* of handling freely and smoothly so many independent parts is the least remarkable of its qualities. An excellent modern edition of it was produced by Dr A. H. Mann in 1888 (London, Weekes & Co.); and, when the reader has overcome the difficulty of reading a score that runs across two pages, he finds himself in the presence of a living classic. The art with which the climaxes are built up shows that Tallis's object in writing for forty voices is indeed to produce an effect that could not be produced by thirty-nine.] These *tours de force*, however, though approachable only by the greatest contrapuntists living in an age in which counterpoint was cultivated with a success that has never since been equalled, serve to illustrate one phase only of Tallis's many-sided genius, which shines with equal brightness in the eight psalm-tunes (one in each of the first eight modes) and unpretending little *Veni Creator*, printed in 1567 at the end of Archbishop Parker's *First Quinquagene of Metrical Psalms*, and many other compositions of like simplicity.

[1] Boyce's unaccountable omission of the very beautiful *Venite* is a misfortune which cannot be too deeply deplored, since it has led to its consignment to almost hopeless oblivion.

In 1575 Tallis and his pupil William Byrd—as great a contrapuntist as himself—obtained from Queen Elizabeth royal letters patent granting them the exclusive right of printing music and ruling music-paper for twenty-one years; and, in virtue of this privilege, they issued, in the same year, a joint work, entitled *Cantiones quae ab argumento Sacrae vocantur, quinque et sex partium*, containing sixteen motets by Tallis and eighteen by Byrd, all of the highest degree of excellence. Some of these motets, adapted to English words, are now sung as anthems in the Anglican cathedral service. But no such translations appear to have been made during Tallis's lifetime; and there is strong reason for believing that, though both he and Byrd outwardly conformed to the new religion, and composed music expressly for its use, they remained Catholics at heart.

Tallis's contributions to the *Cantiones Sacrae* were the last of his compositions published during his lifetime. He did not live to witness the expiration of the patent, though Byrd survived it and published two more books of *Cantiones* on his own account in 1589 and 1591, besides numerous other works. Tallis died November 23, 1585, and was buried in the parish church at Greenwich, where a quaint rhymed epitaph, preserved by Strype, and reprinted by Burney and Hawkins, recorded the fact that he served in the chapel royal during the reigns of Henry VIII., Edward VI., Mary, and Elizabeth. This was destroyed with the old church about 1710; but a copy has since been substituted. Portraits, professedly authentic, of Tallis and Byrd, were engraved by Vandergucht in 1730, for Nicolas Haym's projected *History of Music*, but never published. One copy only is known to exist.

Not many works besides those already mentioned were printed during Tallis's lifetime; but a great number are preserved in MS. It is to be feared that many more were destroyed, in the 17th century during the spoliation of the cathedral libraries by the Puritans. (W. S. R.)

TALLOW (M.E. *talugh*, *talg*, cf. Du. *talk*, L. Ger. *talg*; the connexion with O.E. *taelg*, dye, or Goth, *tulgus*, firm, is doubtful), the solid oil or fat of ruminant animals, but commercially obtained almost exclusively from oxen and sheep. The various methods by which tallow and other animal fats are separated and purified are dealt with in the article OILS. Ox tallow occurs at ordinary temperatures as a solid hard fat having a yellowish white colour. The fat is insoluble in cold alcohol, but it dissolves in boiling alcohol, in chloroform, ether and the essential oils. The hardness of tallow and its melting-point are to some extent affected by the food, age, state of health, &c., of the animal yielding it, the firmest ox tallow being obtained in certain provinces of Russia, where for a great part of the year the oxen are fed on hay. New tallow melts at from 42·5° to 43° C., old tallow at 43·5°, and the melted fat remains liquid till its temperature falls to 33° or 34° C. Tallow consists of a mixture of two-thirds of the solid fats palmitin and stearin, with one-third of the liquid fat olein.

Mutton tallow differs in several respects from that obtained from oxen. It is whiter in colour and harder, and contains only about 30 per cent. of olein. Newly rendered it has little taste or smell, but on exposure it quickly becomes rancid. Sweet mutton tallow melts at 46° and solidifies at 36° C.; when old it does not melt under 49°, and becomes solid on reaching 44° or 45° C. It is sparingly soluble in cold ether and in boiling alcohol.

TALLOW TREE, in botany, the popular name of a small tree, *Stillingia sebifera*, belonging to the family Euphorbiaceae, a native of China, but cultivated in India and other warm countries. The seeds are thickly coated with a white greasy substance—so-called vegetable tallow—from which candles are made, and which is also used in soap-making and dressing cloth. The butter tree or tallow tree of Sierra Leone is *Pentadesma butyracea*, a member of the family Guttiferae. The fruit, which is 4 to 5 in. long and about 3 in. in diameter, has a thick fleshy rind abounding in a yellow greasy juice.

TALLY, an old device, now obsolete, formerly used in the English exchequer for the purpose of keeping accounts. The tally was a willow or hazel stick about one inch in depth and thickness, and roughly shaped like a thick knife-blade (see Fig. 1). Notches (see Fig. 2) were cut on it showing the amount paid, a gauged width of $1\frac{1}{2}$ inches representing £1000, 1 inch £100, $\frac{3}{8}$ inch £10, half a notch of this size representing £1; $\frac{3}{16}$ inch 1s., and the smallest notch 1d.; half-pennies were represented by small holes. The account of the transaction was written on the two opposite sides, the piece of wood being then split down the middle through the notches; one half, called the tally, being given as a form of receipt to the person making the payment, while the other half, called the counter-tally, was kept in the exchequer. Payments made into the exchequer were entered into an account-book, from which they were transferred to a strip of parchment, or *teller's bill*; this was then thrown down a pipe into the *tally-court*, a large room directly under the teller's office. In the tally-court were officers of the clerk of the "pells"[1] and of the auditor as representing the chamberlain of the exchequer. The teller's bill was then entered in the introitus or receipt-book by the officer of the clerk of the pells, and in another book, called the *bill of the day*, by the auditor's clerk. A tally was then made of the teller's bill, and it was given on application, generally on the following day, to the person paying in the money. At the end of the day, the bill of the day was passed on to the clerk of the cash-book, by whom all the day's receipts were entered (see the "Great Account" of *Public Income and Expenditure*, part ii. app. 13, July 1869, by H. W. Chisholm).

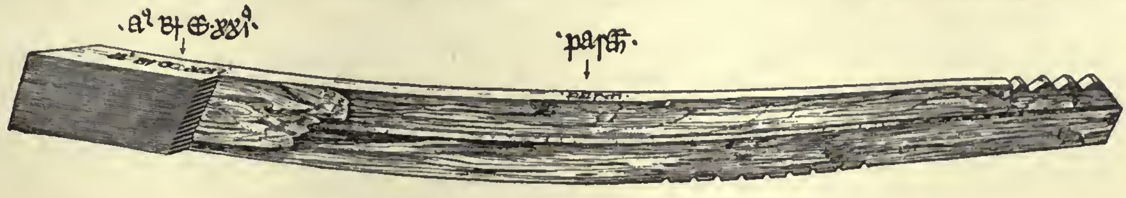

FIG. 1.—A tally ($\frac{3}{4}$ scale) (not the same as that shown in Fig. 2).

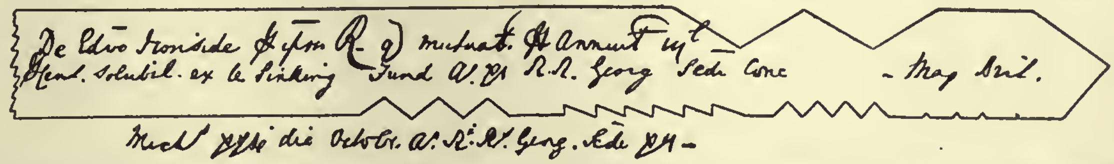

FIG. 2.—Diagrammatic view, showing notches with facsimile of writing, of an Exchequer tally ($\frac{3}{4}$ scale), acknowledging the receipt of £236, 4s. $3\frac{1}{2}$d. on the 25th of October 1739, from Edward Ironside, Esq., as a loan to the king on £3 per cent. annuities payable out of the Sinking Fund, on account of £500,000 granted by Act 11 Geo. II., c. 27. The date is written upon the upper side of the tally, where the two notches denoting £200 are cut. The lower side, on which the smaller notches are cut, has only the word *Sol* written upon it.

The practice of issuing wooden tallies was ordered to be discontinued by an act of 1782; this act came into force on the death of the last of the chamberlains in 1826. The returned tallies were stored in the room which had formerly been the Star-chamber. This room was completely filled by them, so that in 1834, when it was desired to use the room, the tallies were ordered to be destroyed. They were used as fuel for the stoves which warmed the houses of parliament. On the 16th of October 1834 the houses of parliament were burnt down by the overheating of the stoves through using too many of the tallies.

The so-called *tally-trade* was an old system of dealing carried on in London and in the manufacturing districts of England, by which shopkeepers furnished certain articles on credit to their customers, the latter paying the stipulated price for them by weekly or monthly instalments (see M'Culloch, *Dictionary of Commerce*)—the precursor, in fact, of the modern instalment system.

See S. R. Scargill-Bird, *Guide to the Public Records* (*Calendar of State Papers*); H. Hall, *Curiosities and Antiquities of the Exchequer*.

[1] So called from the pells or sheepskins (Lat. *pellis*, skin) on which the records were written. The clerk of the pells was originally the private clerk of the treasurer. His duty was to keep separate records of all monies entering and leaving the exchequer. These records were kept on two rolls, the *pellis introitus*, or pells receipt roll, and the *pellis exitus*, or pells issue roll. The office gradually became a sinecure, its duties being discharged by deputy. Previously to 1783 the salary of the office was derived from fees and percentages, but in that year parliament settled the salary at £1500 a year. The office was abolished in 1834.

TALMA, FRANÇOIS JOSEPH (1763–1826), French actor, was born in Paris on the 15th of January 1763. His father, a dentist there, and afterwards in London, gave him a good English education, and he returned to Paris, where for a year and a half he practised dentistry. His predilection for the stage was cultivated in private theatricals, and on the 21st of November 1787 he made his *début* at the Comédie Française as Seide in Voltaire's *Mahomet*. His efforts from the first won approval, but for a considerable time he only obtained secondary parts. It was as the *jeune premier* that he first came prominently into notice, and he attained only gradually to his unrivalled position as the exponent of strong and concentrated passion. Talma was among the earliest advocates of realism in scenery and costume, being aided by his friend the painter David. His first essay in this direction took the form of appearing in the small rôle of Proculus in Voltaire's *Brutus*, with a toga and Roman head-dress, much to the surprise of an audience accustomed to 18th century costume on the stage, and heedless whether or not it suited the part played. Talma possessed in perfection the physical gifts fitting him to excel in the highest tragedy, an admirably proportioned figure, a striking countenance, and a voice of great beauty and power, which, after he had conquered a certain thickness of utterance, enabled him to acquire a matchless elocution. At first somewhat stilted and monotonous in his manner, he became by perfection of art a model of simplicity. Talma married Julie Carreau, a rich and talented lady in whose salon were to be met the principal Girondists. The actor was an intimate friend of Napoleon, who delighted in his society, and even, on his return from Elba, forgave him for performing before Louis XVIII. In 1808 the emperor bad taken him to Erfurt and made him play the *Mort de César* to a company of crowned heads. Five years later he took him also to Dresden. Talma was also a friend of Joseph Chénier, Danton, Camille Desmoulins and other revolutionists. It was in Chénier's anti-monarchical *Charles IX.*, produced on the 4th of November 1789, that a prophetic couplet on the destruction of the Bastille made the house burst into a salvo of applause, led by Mirabeau. This play was responsible for the political dissensions in the Comédie Française which resulted in the establishment, under Talma, of a new theatre known for a time as the Théâtre de la République, on the site of the present Théâtre Français. Here he won his greatest triumphs. Further development in costume and make-up was shown in his stage portrait of Jean Jacques Rousseau (1790), pronounced a wonderful likeness in *Le journaliste des ombres*. In 1801 he divorced his wife, and in 1802 married Charlotte Vanhove, an actress of the Comédie Française. He made his last appearance on the 11th of June 1826 as Charles VI. in Delaville's tragedy, and he died in Paris on the 19th of October of that year.

Talma was the author of *Mémoires de Lekain, précédés de réflexions sur cet acteur et sur l'art théâtral*, contributed to the *Collection des mémoires sur l'art dramatique*, and published separately (1856) as *Réflexions de Talma sur Lekain et l'art théâtral*.

See *Mémoires de F. J. Talma, écrits par lui-même, et recueillis et mis en ordre sur les papiers de sa famille*, by Alex. Dumas (1850).

TALMAGE, THOMAS DE WITT (1832–1902), American Presbyterian preacher, born at Bound Brook, New Jersey, on the 7th of January 1832. He was educated at the University of the City of New York (now New York University) and at the Reformed Dutch Theological Seminary at New Brunswick, N.J., from which he was graduated in 1856. Immediately afterwards he became pastor of a Reformed church at Belleville, N.J. In 1859 he removed to Syracuse, N.Y.; in 1862 to Philadelphia, where he was pastor of the Second Reformed Dutch Church; and in 1869 to the Central Presbyterian Church in Brooklyn, where a large building known as the Tabernacle was erected for him in 1870. In 1872 this building was burned down. A larger one, holding 5000 persons, was built for him in 1873, but even this could not contain the crowds attracted by his eloquence and sensationalism. In 1889 this church also was burned to the ground, only to be succeeded by another and larger one, which in its turn was burned in 1894. Shortly afterwards he removed to Washington, where from 1895 to 1899 he was the associate pastor, with Dr Byron Sunderland (d. 1901), of the First Presbyterian Church. During the last years of his life Dr Talmage ceased to preach, and devoted himself to editing, writing and lecturing. At different periods he was editor of the *Christian at Work* (1873–76), New York; the *Advance* (1877–79), Chicago; *Frank Leslie's Sunday Magazine* (1879–89), New York; and the *Christian Herald* (1890–1902), New York. For years his sermons were published regularly in more than 3000 journals, reaching, it is said, 25,000,000 readers. His books also have had large circulations; among them are *The Almond Tree in Blossom* (1870); *Every Day Religion* (1875); *The Brooklyn Tabernacle* (1884); *From Manger to Throne* (1895); and *The Pathway of Life* (1895). His eloquence, while sensational, was real and striking, and his fluency and the picturesqueness of his language and imagery were remarkable. He died at Washington on the 12th of April 1902.

TALMUD, the great Rabbinical thesaurus which grew up during the first four or six centuries of the Christian Era, and, with the Old Testament, became the "Bible" of the Jews, and the chief subject of their subsequent literary activity.

1. *Contents*.—The Talmūd (Hebrew "teaching, learning") consists of the *Mishnāh* (Heb. "[oral] repetition, teaching"), a systematic collection of religious-legal decisions developing the laws of the Old Testament, and the *Gĕmārā* (Aramaic "completion, decision," or perhaps also "teaching"), supplementary material, legal and otherwise.[1] The whole was in two great recensions, Palestinian and Babylonian. Other material related to the Mishnāh is preserved in the *Tōsephtā* (Aram. "addition") and the *Midrāshīm*, and since all these, together with the *Targūmīm*, represent the orthodox Rabbinical literature connecting the Old Testament with medieval and modern Judaism, the reader should also consult the articles JEWS (parts ii. and iii.), MIDRASH, TARGUM, and for more detailed and critical treatment the references given to the *Jewish Encyclopedia*.

[1] Mishnah stands in contrast to *Miqrā* ("reading, scripture"); its Aram. equivalent is *Mathnīthā*, from *tĕnā*, "to repeat," whence the appellation *Tannā*, "teacher" (§ 3 below). These and the terms Gemara, Talmud, &c., are more fully explained in H. L. Strack's invaluable *Einleitung in den Talmud* (Leipzig, 1908), pp. 2 sqq.

The Mishnah is a more or less careful arrangement of the extant Oral Law (see § 2). It forms the foundation of the Gemara, and is divided into six *Sĕdārīm* or Orders, each containing a number of *Massektōth* ("weavings," cf. the etymology of "text") or Tractates. These are subdivided into *Pĕrāqīm* ("sections") or chapters, and these again into paragraphs or sentences.

I. *Zĕra'īm* ("seeds"), the first Order, on agriculture, is introduced by (1) *Bĕrākōth* ("blessings"), on daily and other prayers and blessings. (2) *Pē'āh* ("corner"), deals with Lev. xix. 9 seq., xxiii. 22; Deut. xxiv. 19–22, and the rights of the poor. (3) *Dĕmai*, or rather *Dammai* ("doubtful"), on doubtful cases relating to the tithing of fruit offerings. (4) *Kil'ayim* ("of two sorts"), on forbidden mixtures (Lev. xix. 19; Deut. xxii. 9–11). (5) *Shĕbī'īth* ("seventh"), on the sabbatical year (Ex. xxiii. 11; Lev. xxv. 1–8; Deut. xv. 1 sqq.). (6) *Tĕrūmōth* ("heave offerings"), on the laws in Num. xviii. 8 sqq., 25 seq.; Deut. xviii. 4. (7) *Ma'asrōth* ("tithes") or *Ma'asēr Rī'shōn* ("first tithe"), with reference to the Levites, Num. xviii. 21–24. (8) *Ma'asēr Shēnī* ("second tithe"), with reference to the tithe eaten at Jerusalem, Deut. xiv. 22–26. (9) *Ḥallāh* ("cake"), on Num. xv. 18–21. (10) *'Orlāh* ("foreskin" [of trees]), on Lev. xix. 23–25. (11) *Bikkūrīm* ("first-fruits"), on Ex. xxiii. 19; Deut. xxvi. 1 sqq. The fourth chapter of this treatise, printed in most editions, is properly a Baraitha.

II. *Mō'ēd* ("festival"). (1) *Shabbāth*, on the Sabbath as a day of rest, Ex. xx. 10, xxiii. 12; Deut. v. 14, &c. (useful edition by Strack, 1890). (2) *'Ērūbīn* ("mixtures" or amalgamations), on legitimate methods of avoiding inconvenient restrictions on the Sabbath. (3) *Pĕsāḥīm* ("passovers"—sacrifices and meals), on Ex. xii., xiii. 6–8, xxiii. 15; Lev. xxiii. 5 sqq.; Num. xxviii. 16 sqq.; Deut. xvi. 1 sqq., &c. (4) *Shĕqālīm* ("shekels"), on the poll tax (Ex. xxx. 12 sqq.; Neh. x. 33). (5) *Yōmā* (Aram. "the day"), or *Kippūrīm* ("atonement"), or *Y. ha-k.* ("the day of atonement"), on Lev. xvi., xxiii. 26–32 (useful edition by H. L. Strack, Leipzig, 1904). (6) *Sukkāh* or *Sukkōth* ("booth[s]"), on Lev. xxiii. 34 sqq.; Num. xxix. 12 sqq.; Deut. xvi. 13–16. (7) *Bēṣāh* ("egg," the opening word) or *Yōm tōb* ("good [*i.e.* feast] day"), general rules for feast-days. (8) *Rōsh ha-Shānāh* ("New Year festival"), on the services, the calendar, and more particularly on the first of the Seventh Month (cf. Num. x. 10, xxviii. 11 sqq., &c.). (9) *Ta'anīth* or *Ta'aniyyōth*, *i.e.* "fast[s]," special observances relating thereunto; in particular to public fasts appointed in time of drought. (10) *Mĕgillāh*, "roll" (of Esther), the reading of it at Purim, &c. (11) *Mō'ēd qāṭōn* ("the small M," to distinguish it from the name of this order), or *Mashkīn* (the first word), regulations for the intermediate festivals at Passover and Tabernacles. (12) *Ḥăgīgāh* ("festival"), on the three principal festivals, Deut. xvi. 16, the duty of pilgrims and the defilements to be avoided (transl. from Bab. Talm. by A. W. Streane, Camb., 1891).

III. *Nāshīm* ("women"). (1) *Yĕbāmōth* ("sisters-in-law"), on the levirate, &c. (2) *Kĕthūbōth* ("marriage contracts"), rights and duties of husband and wife. (3) *Nĕdārīm* ("vows"), on Num. xxx. (4) *Nāzīr* ("Nazirite"), on Num. vi. (5) *Giṭṭīn* ("documents"), on divorce and separation. (6) *Sōṭāh* ("the faithless woman"), on Num. v. 11–31. (7) *Qiddūshīn* ("sanctifications" of marriage), on the contraction of legal marriage.

IV. *Nĕzīqīn* ("damages"), also known as *Yĕshū'ōth* ("deeds of help"). (1) *Bābā qammā* (Aram. "the first gate"), on injuries and compensation; civil law. (2) *B. Mĕṣī ā* (Aram. "the middle gate"), on sales, leases, lost property. (3) *B. Bathrā* (Aram. "the last gate"), on real estate, succession, &c. (4) *Sanhedrīn* (συνέδριον), on procedure and criminal law. (5) *Makkōth*, "blows," on the number to be inflicted (Deut. xxv. 1–3) and for what offence, &c. (6) *Shĕbū'ōth* ("oaths"), on Lev. v. 4 sqq. (7) *'Ēduyyōth*, "testimonies," viz. of later teachers regarding their predecessors, on the schools of Hillel and Shammai, 'Aqiba, &c., important for the problem of the literary growth of the Mishnah. (8) *'Ăbōdāh Zārāh* ("idolatrous worship"), regulations in reference to heathen idolatry (useful edition with Germ. transl. by Strack, 1909; and including that of the Gemara by F. C. Ewald, Nuremberg, 1856). (9) *'Abōth* or *Pirqē* A. ("sayings of the fathers"), a famous collection of maxims; the sixth chapter on "the possession of the law" does not properly belong to the Mishnah (ed. with transl. by C. Taylor, Camb. 1897, and in German by H. L. Strack, 1901). (10) *Hōrāyōth* ("decisions"), on judicial and other errors (Lev. iv. 1 sqq.).

V. *Qŏdāshīm* ("holy things"). (1) *Zĕbāḥīm* ("sacrifices"), or *shĕḥīṭath qŏdāshīm* ("the slaughter of holy things"), on the sacrificial laws, &c. (2) *Mĕnāḥōth* ("meat-offerings"), on Lev. ii. 5, 11–13, vi. 7–16, xiv. 10–20, &c. (3) *Ḥullīn* or *Shĕḥīṭath H.* ("[the slaughter of] common things"), on non-sacrificial meat. (4) *Bĕkōrōth* ("first-born"), on firstlings (Ex. xiii. 12 seq.; Lev. xxvii. 26 seq.; Num. viii. 16–18, xviii. 15–17; Deut. xv. 19 sqq.). (5) *'Arākīn* ("valuations" for ransom, &c.), on Lev. xxv. 15–28, 29 sqq., xxvii. 2 sqq., 28 seq. (6) *Tĕmūrāh* ("exchange" of dedicated animals), cf. Lev. xxvii. 10, 33. (7) *Kĕrīthōth* ("cutting off"), on excommunication, &c. (8) *Mĕ'īlāh* ("trespass"), on Lev. v. 15 sqq.; Num. v. 6–8. (9) *Tāmīd*, on the "continual or perpetual (daily burnt offering)," Ex. xxix. 38–42; Num. xxviii. 2–8. (10) *Middōth* (" measures "), an important tractate on the temple (measurements, gates, halls, &c.). (11) *Qinnīm* (" nests "), on sacrifices of doves by the poor (cf. Lev. i. 14–17, v. 1 sqq., xii. 8).

VI. *Ṭohŏrōth* or *Ṭĕh.*, " purifications," a euphemism for things which are ritually or ceremonially " unclean." (1) *Kēlīm* (" vessels "), their uncleanness (cf. Lev. xi. 32 sqq.; Num. xix. 14 sqq., xxxi. 20 sqq.). (2) *Ohālōth* (" tents "), on defilement through a corpse (Num. xix. 14–20), &c. (3) *Nĕgā'īm* (" plagues," *i.e.* leprosy), on Lev. xiii. seq. (4) *Pārāh* (the [red] " heifer "), on Num. xix. (5) *Ṭĕhārōth* (euphemism for impurities), on minor defilements. (6) *Miqwā'ōth* (ritual baths), bathing for the defiled (cf. Lev. xiv. 8, xv. 5 sqq.; Num. xxxi. 23; also Mark vii. 4). (7) *Niddāh* (female " impurity "), on Lev. xv. 19–33. (8) *Makshīrīn* (" predisposing "), or *Mashqīn* (" liquids "), on defilement caused by wet unclean things (cf. Lev. xi. 34, 37 seq.). (9) *Zābīm* (" those with a discharge "), on Lev. xv. (10) *Tĕbūl Yōm* (" immersed for [or on] the day "), on those who have taken a ritual bath and must wait until sunset before becoming ritually pure (see Lev. xv. 5, xxii. 6 seq.; Num. xix. 19). (11) *Yādāyīm*, " hands," their purification (cf. Matt. xv. 2, 20; Mark vii. 2–4, &c.). (12) *Ūqṣīn* (" stems "), on the relation between fruit and the stems and stalks as regards defilement, &c.

To Order IV. the Babylonian recension of the Talmud adds seven treatises, which are of later origin and are regarded as more or less extra-canonical. (1) *Ābōth dĕ Rabbi Nathan*, an expansion of IV. 9, attributed to a second-century Rabbi, but post-Talmudic (ed. S. Schechter, 1887). (2) *Sōphĕrīm* (" scribes "), on the writing of the scrolls of the Pentateuch, grammatical (Massoretic) rules, and (a later addition) on the liturgy (ed. J. Müller, Leipzig, 1878). (3) *Ēbel Rabbāthi* (" great weeping "), or, euphemistically, *Sĕmāḥōth* (" joys "), on mourning customs and rules. (4) *Kallāh* (" betrothed, bride "), on chastity in marriage, &c. *Dĕrek Ēreṣ* (5) *Rabbah*, and (6) *Zūṭā*, a " large " and a " small " treatise on various rules of " conduct " and social life. (7) *Pĕreq ha-Shālōm*, a " chapter on peace " (peacefulness). In addition to these seven, other small Talmudic treatises are also reckoned (edited by R. Kirchheim, Frankfort-on-Main, 1850). These deal with (1) the writing of the rolls of the Law; (2) *Mĕzūzāh* (Deut. vi. 9, xi. 20); (3) *Tĕphillīn* (prayers, phylacteries); (4) the fringes (Num. xv. 38); (5) slaves; (6) the Samaritans (see J. A. Montgomery, *The Samaritans*, pp. 196 sqq.); and (7) proselytes.

The Mishnah itself contains 63 tractates, or, since IV. 1–3 originally formed one (called *Nĕzīqīn*) and IV. 4, 5 were united, 60. The number is also given as 70 (cf. 2 Esd. xiv. 44–46), perhaps by including the seven smaller treatises appended to IV. There are 523 chapters (or 525, see I. 11, IV. 9).

2. *The Origin of the Mishnah.*—A careful distinction was drawn between the Written Law, the Mosaic Tōrāh, and the rest of the Scriptures (תּוֹרָה שֶׁבִּכְתָב), and the Oral Law, or Tōrāh by Mouth (תּוֹרה שֶׁבְּעַל פֶּה). The origin of the latter, which has become codified in the Mishnah, has often been discussed. It was supposed that it had been handed down by Ezra; that it was indebted to Joshua, David or Solomon; that it was as old as Moses, to whom it had been communicated orally or in writing, complete or in its essence. The traditional view is well illustrated in the words ascribed to R. Simeon Lakish, 3rd century A.D.:[1] " What is that which is written, ' I will give thee the tables of stone, and the Law and the Commandment, which I have written, that thou mayest teach them (Ex. xxiv. 12) '? ' Tables,' these are the Ten Words (the Decalogue); the ' Law ' is the Scripture; ' and the commandment,' that is the Mishnah: ' which I have written,' these are the Prophets and Writings (*i.e.* The Hagiographa), ' to teach them,' that is the Gemara—thus instructing us that all these were given to Moses from Sinai." Literary and historical criticism places the discussion on another basis when it treats the Mosaic Tōrāh *in its present form* as a post-exilic compilation (about 5th century B.C.) from sources differing in date, origin and history. There is no *a priori* reason why other legal enactments should not have been current when the compilation was first made; the Pentateuchal legislation is incomplete, and covers only a small part of the affairs of life in which legal decisions might be needed. There must have been a large body of usage to which Jewish society subscribed; customary usage is one of the most binding of laws even among modern Oriental communities where laws in writing are unknown, and one of the most interesting features is the persistence in the East of closely-related forms and principles of custom from the oldest times to the present day. Laws must be adjusted from time to time to meet changing needs, and new necessities naturally arose in the Greek and Roman period for which the older codes and usages made no provision. Much in the same way as Roman law was derived from the Twelve Tables, the Jewish written laws were used as the authority for subsequent modifications, and the continuity of the religious-legal system was secured by a skilful treatment of old precedents.[2] In the article MIDRASH it will be seen that new teaching could justify itself by a re-interpretation of the old writings, and that the traditions of former authoritative figures could become the framework of a teaching considerably later than their age. It is probable that this process was largely an unconscious one; and even if conscious, the analogy of the conventional " legal fiction " and the usual anxiety to avoid the appearance of novelty is enough to show that it is not to be condemned. By the help of a tradition —a " haggadic " or " halakic " Midrash (*q.v.* § 1)—contemporary custom or ideals could appear to have ancient precedents, or by means of an exegetical process they could be directly connected with old models. In the Old Testament many laws in the Mosaic legislation are certainly post-Mosaic and the value of not a few narratives lies, not in their historical or biographical information, but in their treatment of law, ritual, custom, belief, &c. Later developments are exemplified in the pseudepigraphical literature, notably in the Book of Jubilees, and when we reach the Mishnah and Talmud, we have only the first of a new series of stages which, it may be said, culminate in the 16th-century *Shulḥan 'Ārūk*, the great compendium of the then existing written and oral law. Thus, the problem of the origin or antiquity of the unwritten Oral Law, a living and fluid thing, lies outside the scope of criticism; of greater utility is the study of the particular forms the laws have taken in the written sources which from time to time embody the ever-changing legacy of the past.

The course of development between the recognition of the supremacy of the Pentateuch and the actual writing down of the Mishnah and Gemara can be traced only in broad lines. It is known that a great mass of oral tradition was current, and there are a number of early references to written collections, especially of haggadah. On the other hand, certain references indicate that there was a strong opposition to writing down the Oral Law. It is possible, therefore, that written works were in circulation among the learned, and that these contained varying interpretations which were likely to injure efforts to maintain a uniform Judaism. Philo speaks of μυρία ἄγραφα ἔθη καὶ νόμιμα (ed. Mangey, ii. 629), and the oral esoteric traditions of the Pharisees are attested by Josephus (xiii. 10, 6, cf. 16, 2); cf. in the New Testament, Matt. xv. 1–9, Mark vii. 8, &c.; and the δευτερώσεις " repetitions " (cf. the term Mishnah) of the Christian Fathers. For the *written* collections, see Strack, *op. cit.*, pp. 10 sqq.; J. Theodor, *Jew. Ency.*, viii. 552; J. Z. Lauterbach, *ib.*, p. 614; W. Bacher, *ib.*, xii. 19; S. Schechter, *Hastings' Dict. Bible*, v. 62; and art. MIDRASH, § 5, in this work. The theory of an esoteric tradition is distinctly represented in 2 Esdras xiv., where Moses receives words which were not to be published, and Ezra re-writes seventy books which were to be delivered to the wise men of his people. Also the Book of Jubilees knows of secret written traditions containing regulations regarding sacrifices, &c., and Jacob hands over " all his books and the books of his fathers to Levi his son that he might preserve them and renew them for his children (*i.e.* the priestly caste) unto this day " (xlv. 16).

3. *Growth of the Mishnah and Gemara.*—According to the traditional view the canon of the Old Testament closed with the work of Ezra. He was followed by the *Sōphĕrīm*, " scribes " (or the Men of the great Synagogue), to the Maccabaean age, and these again by the " Pairs " (*zūgōth*, Gr. ζυγόν), the reputed heads of the Sanhedrin, down to the Herodian age (150–30 B.C.). The last culminate in Hillel (*q.v.*) and Shammai, the founders of two great rival schools, and to this famous pair the work

[1] For the sake of convenience Ben (" son ") and Rabbi are, as usual, abbreviated to b. and R. For the quotation which follows, see Oesterley and Box, *The Religion and Worship of the Synagogue* (London, 1907) p. 51; and, on the subject, S. Schechter, *Studies in Judaism* (London, 1896), ch. vii.—" the history of Jewish tradition "; E. Weber, *Jüdische Theologie* (Leipzig, 1897), pp. 91 seq. and 130 sqq.; Strack, *op. cit.*, p. 8 seq.; W. Bousset, *Relig. d. Judentums* (Berlin, 1906), pp. 176 sqq., and *Jew. Ency.*, iv. 423 sqq.; see also G. B. Gray's art. " Law Literature " in the *Ency. Bib.*

[2] See W. R. Smith, *Old Test. in the Jewish Church*, p. 51 seq., 160.

of collecting *hălākōth* ("legal decisions") has been ascribed. The ensuing period of the *Tannā'īm*, "teachers" (about A.D. 10–220), is that of the growth of the Mishnah.[1] Among the best known representatives of the schools are Rabban (a title given to Hillel's descendants) Gamaliel, the Phil-Hellene and teacher of the apostle Paul (Acts xxii. 3) and his son Simeon (Josephus, *Life*, § 38 seq., *Wars*, iv. 3, 9), and Rabban Joḥanan b. Zakkai, founder of the seat of learning at Jamnia (Jabneh). A little later (about 90–130 A.D.) are the famous Gamaliel II., Eliezer b. Hyrqanos (at Lydda), and Ishmael b. Elisha, the last of whom founded the school at Usha and is renowned for his development of the rules of exegesis framed by Hillel. With Rabbi Aqība (*q.v.*) and the synods of Jamnia (about 90 and 118 A.D.) a definite epoch in Judaism begins. At Jamnia, under the presidency of Gamaliel II. and Eleazar b. Azariah, a collection of traditional *halakoth* was formed in the tractate *'Eduyyōth* (larger than and not to be identified with IV., 7 above). Here, too, was discussed the canonicity of the Song of Songs and of Ecclesiastes, and it is probable that here Aqība and his colleagues fixed the official text of the canonical books. Aqība had an important share in the early development of the Mishnah (Strack, pp. 19, 89); and, in the collecting of material, he was followed notably by the school of Ishmael (about 130–160 A.D.), which has left its mark upon the early halakic Midrashim (see MIDRASH, § 5, 1–3). The more interesting names include R. Meir, a well-known haggadist, R. Simeon b. Yoḥai, R. Jose b. Ḥalaphta and R. Jehudah b. 'El'ai. But, as collections of decisions were made by prominent teachers from time to time, confusion was caused by their differences as regards both contents and teaching (*Sotah*, 22*a*; *Shabb.* 138*b*). Consequently, towards the close of the second century a thoroughly comprehensive effort was made to reduce the *halakoth* to order. Judah, grandson of Gamaliel II., known as the Prince or Patriarch (*nāsī'*), as *Rabbēnū* ("our teacher"), or simply as "Rabbi" *par excellence*, was the editor. He gathered together the material, using Meir's collection as a basis, and although he did not write the Mishnah as it now is, he brought it into essentially its present shape. His methods were not free from arbitrariness; he would attribute to "the wise" the opinion of a single authority which he regarded as correct; he would ignore conflicting opinions or those of scholars which they themselves had afterwards retracted, and he did not scruple to cite his own decisions.[2]

The period of the *'Ămōrā'īm*, "speakers, interpreters," (about 220–500 A.D.), witnessed the growth of the Gemara, when the now "canonical" Mishnah formed the basis for further amplification and for the collecting of old and new material which bore upon it. In Palestine learning flourished at Caesarea, Sepphoris, Tiberias and Usha; Babylonia had famous schools at Nehardea (from the 2nd century A.D.), Sura, Pumbeditha and elsewhere.[3] Of their teachers (who were called Rabbi and Rab respectively) several hundreds are known. R. Ḥiyya was redactor of the *Siphrā* on Leviticus (MIDRASH, § 5, 2); to him and to R. Hoshaiah the compilation of the *Tōsephtā* is also ascribed. Abbā Arīka or Rab, the nephew of the first mentioned, founded the school of Sura (219 A.D.). Rab and Shemuel (Samuel) "the astronomer" (died 254 A.D.) were pupils of "Rabbi" (*i.e.* Judah, above), and were famed for their knowledge of law; so numerous were their points of difference that the Talmud will emphasize certain decisions by the statement that the two were agreed. The Gemara is much indebted to this pair and to Joḥanan b. Nappāḥā (199–279). The latter, founder of the great school of Tiberias, has indeed been venerated, on the authority of Maimonides, as the editor of the Palestinian Talmud; but the presence of later material and of later names, *e.g.* Manī b. Jona and Jose b. Abin (Abun), refute this view. The Babylonian Rabbah b. Naḥmani (d. *c.* 330) had a dialectical ability which won him the title "uprooter of mountains." His controversies with R. Joseph b. Ḥiyya (known for his learning as "Sinai"), and those between their disciples Abayi and Rābā are responsible for many of the minute discussions in the Babylonian Gemara. Meanwhile the persecutions of Constantine and Constantius brought about the decay of the Palestinian schools, and, probably in the 5th century, their recension of the Talmud was essentially complete. In Babylonia, however, learning still flourished, and with Rab Ashi (352–427) the arranging of the present framework of the Gemara may have been taken in hand. Under Rabba Tosĕpha'a (died 470) and Rabina, *i.e.* Rab Abina (died 499), heads of the academy of Sura, the Babylonian recension became practically complete.

Finally, the *Sabōrā'ē*, "explainers, opiners" (about 500–540), made some additions of their own in the way of explanations and new decisions. They may be looked upon as the last editors of the now unwieldy thesaurus; less probable is the view, often maintained since Rashi (11th century), that it was first written down in their age.[4]

4. *The Two Talmuds.*—The Palestinian recension of the Mishnah and Gemara is called "the Talmud of the Land of Israel," or "T. of the West"; a popular but misleading name is "the Jerusalem Talmud." It is an extremely uneven compilation. "What was reduced to writing does not give us a work carried out after a preconcerted plan, but rather represents a series of jottings answering to the needs of the various individual writers, and largely intended to strengthen the memory" (Schechter). Political troubles and the unhappy condition of the Jews probably furnish the explanation; hence also the abundance of Palestinian haggadic literature in the Midrashim, whose "words of blessing and consolation" appealed more to their feelings than did the legal writings. The Pal. Talmud did not attain the eminence of the sister recension, and survives in a very incomplete form, although it was perhaps once fuller. It now extends only to Orders I.–IV., with the omission of IV. 7 and 9, and with the addition of part of VI. 7.[5] The Babylonian Talmud (or Tal. Babli) contains the Gemara to $36\frac{1}{2}$ tractates, but the material is relatively very full, and it is about three times as large as the Pal., although the Gemara there extends to 39 tractates. In the latter the Gemara follows each paragraph of the Mishnah; in the former, references are usually made to the leaves (the two pages of which are called *a* and *b*), the enumeration of the *editio princeps* being retained in subsequent editions. The Mishnah is written in a late literary form of Hebrew; but the Gemara is in Aramaic (except the *Baraithas*), that of the Bab. T. being an Eastern Aram. dialect (akin to Mandaitic), that of the Pal. T. being Western Aram. (akin to Biblical Aram. and the Targums). Greek was well understood in cultured Palestine; hence the latter recension uses many Greek terms which it does not explain; whereas in the Bab. T. they are much less common, and are sometimes punningly interpreted.[6] The Pal. Tal. is the more concise, but it is remarkable for the numerous repetitions of the same passages; these are useful for the criticism of the text, and for the light they throw upon the incompleteness of the work of compilation. The Bab. Tal., on the other hand, is diffuse and freer in its composition, and it is characterized by the exuberance of Halakah, which is usually rather subtle and far-fetched. Both Talmuds offer a good field for research (see below). Especially interesting are the *Baraithas* which are preserved in the Gemara in *Hebrew*; they are "external" decisions not included in the more authoritative

[1] On the various teachers, especially the Haggadists, see W. Bacher, *Agada der Babylon. Amoräer* (Strassburg, 1879), *A. d. Tannaiten* (1884, new edition begun in 1903), *A. d. Pal. Amoräer* (1892).

[2] See the criticisms in *Jew. Ency.*, viii. 612, and J. Bassfreund, *Monatsschrift f. d. Gesch. u. Wissens. d. Judentums*, 1907, pp. 427 sqq. On the earlier stages, see *Jew. Ency.*, viii. 610, and Hastings' *Dict. Bible*, v. 61, col. 2, with the references.

[3] On these schools, see art. JEWS, § 42 seq.; and *Jew. Ency.*, i. 145–148.

[4] See Strack, p. 16 seq. The view has little in its favour, although memory played a more important part then than now. For early mnemonic aids to the Mishnah, see Strack, p. 68, *Jew. Ency.*, xii. 19.

[5] The Mishnah was first critically edited by W. H. Lowe (Cambridge, 1883).

[6] The Greek words are treated by S. Krauss and I. Löw, *Griech. u. Lat. Lehnwörter* (Berlin, 1898–9). For the Persian elements in the Bab. T., see *Jew. Ency.*, vii. 313.

Mishnah, but they differ from and are sometimes older than the Mishnic material, with which they sometimes conflict (so in particular as regards the rejected decisions of the school of Shammai). They usually begin: "our Masters taught," "it is taught," or "he taught," the verb *tĕnā* (cf. *Tannā'īm*, "teachers") being employed (see further *Jew. Ency.*, ii. 513 seq.). Parallel to the Mishnah is the *Tōsephtā*, an independent compilation associated with R. Nehemiah (a contemporary of Meir and Simeon b. Yoḥai), Ḥiyya b. Abba and others; it is arranged according to the Mishnic orders and tractates, but lacks IV. 9 and V. 9–11. The halakoth are fuller and sometimes older than the corresponding decisions in the Mishnah, and the treatment is generally more haggadic.[1] The method of making the discussions part of an interpretation of the Old Testament (halakic Midrash), as exemplified in the *Tōsephtā*, is apparently older than the abstract and independent decisions of the Mishnah—which presuppose an acquaintance with the Pentateuchal basis—and, like the employment of narrative or historical Midrash (*e.g.* in the Pentateuch, Chronicles and Jubilees), was more suitable for popular exposition than for the academies. For other halakic literature which goes back to the period of the Tannā'īm, see the *Mekiltā*, *Siphrā* and *Siphrē*, art. MIDRASH, § 5, 1–3.

The Palestinian Talmud, although used by the Qaraites in their controversies, fell into neglect, and the Babylonian recension became, what it has since been, the authoritative guide. With the *Gĕōnīm*, the heads of Sura and Pumbeditha (about 589–1038), we enter upon another stage. The "canonical" Mishnah and Gemara were now the objects of study, and the scattered Jews appealed to the central bodies of Judaism in Babylonia for infofmation and guidance. The Geonim in their "Responses" or "Questions and Answers" supplied authoritative interpretations of the Old Testament or of the Talmud, and regulated the application of the teaching of the past to the changed conditions under which their brethren now lived. The legal, religious and other decisions formulated in the pontifical communications of one generation usually became the venerated teaching of the next, and a new class of literature thus sprang into existence. (See GAON.) Meanwhile, as the Babylonian schools decayed, Talmudic learning was assiduously pursued outside its oriental home, and some Babylonian Talmudists apparently reached the West. However, the fortunes of the Talmud in a hostile world now become part of the history of the Jews, and the many interesting vicissitudes cannot be recapitulated here. (See JEWS, §§ 44 sqq.) To the use of the Pal. Talmud by the Qaraites in their controversies with the Rabbis we owe the preservation of this recension, incomplete though it is. To the intolerance of Christians are no doubt due the rarity of old MSS., and the impure state of the text of both Talmuds. At the same time, the polemics had useful results since the literary controversy in the 16th century (when Johann Reuchlin took the part of the Jews) led to the *editio princeps* of the Babylonian Talmud (Vienna, 1520–23). A change shows itself in the second edition (Basel, 1578–81), when the *'Abōdāh Zārāh* (above, § 1. IV. 8) was omitted, and passages which offended the Christians were cancelled or modified.[2]

Owing to the nature of its contents the Talmud stood sorely in need of aids and guides, and a vast amount of labour (of varying value) has been devoted to it by Jewish scholars. Of the many commentaries the first place must be given to that of R. Solomon Izhaki of Troyes (see RASHI); his knowledge of contemporary tradition and his valuable notes make it a new starting point in the interpretation of the Talmud. To Rashi's disciples are due the *Tōsāphōth* "additions," which, with the commentary of "*the* Commentator," as he was styled, are often reproduced in printed editions of the Talmud. This school (France and Germany, 12th to 13th century) developed a casuistical and over-ingenious interpretation—in contrast to the Spanish Talmudists who aimed at simplification and codification—and it drew upon it the saying of Naḥmanides (13th cent.): "They try to force an elephant through the eye of a needle." Important also are the introduction to and commentary upon the Mishnah by Maimonides (*q.v.*), and the commentary of Rabbenu Obadiah di Bertinoro (died 1510). Both have often been printed; they were translated by Surenhusius (Amsterdam, 1698–1703). See *Jew. Ency.*, xii. 27–30.

Systematic abstracts of the legal parts of the Talmud were made by Isaac Alfazi (or "Riph," 1013–1103), and by Maimonides (*Mishneh Torah*, otherwise called *Sepher ha-Yād* or *Yād ha-Ḥăzākāh*). The latter prepared a great summary of all Jewish religious and civil law, the standard work upon which Christian theologians from the 16th century onwards based their studies—and also their criticisms—of *early* Rabbinism. Jacob b. Asher b. Yeḥiel in his *Ṭūrīm* ("rows") presented a well-arranged collection of those laws which had not become obsolete together with the addition of new ones. Most important of all, however, is Joseph Caro's *Shulḥān 'Ārūk* ("prepared table"), which came in the age of printing (1565), leapt into popularity, and has been, in its turn, the subject of many commentaries and hand-books. This great work systematized Talmudic law in all its developments, ancient and modern, written and oral (I. Abrahams, *Jew. Lit.*, London, 1906, p. 147 seq.; see also *Jew. Ency.*, iii., 584 sqq.). The lengthy history of the written and oral law thus reached its last stage in a work which grew out of the Talmud but had its roots in a more distant past. It was at the dawn of a period when the ancient codes which had been continuously reinterpreted or readjusted were to be re-examined under the influence of newer ideas and methods of study.[3]

The haggadic portions of the Talmud were collected: (*a*) from the Bab. recension, in the *Haggadoth ha-Talmud* (Constantinople, 1511) and in Jacob ibn Ḥabib's *'En* (eye, well of) Jacob (Salonika, 1516); and (*b*) from the Pal., by Samuel Yapheh (Venice, 1589), and in the Yalkūt Shimeoni (see MIDRASH, § 5, 9). These are superseded by the recent translations made by A. Wünsche (Jer. T., Zürich, 1880; Bab. T., Leipzig, 1886–9).

The standard lexicon was the *'Ārūk(h)* of Nathan b. Yeḥiel of Rome (*c.* 1100) which underlies all subsequent works, notably the great *Aruch Completum* of A. Kohut (Vienna, 1878–1892; supplement, New York, 1892); see further *Jew. Ency.*, iv. 580 seq. Modern dictionaries of the older Rabbinical writings have been made by J. Levy (Leipzig, 1876), M. Jastrow (London and New York, 1886), G. Dalman (Frankfort-on-Main, 1901). More technical is W. Bacher's *Exeget. Terminologie d. jüd. Traditions-lit.* (Leipzig, 1905).

The grammatical aids are modern. For Mishnic Hebrew, see A. Geiger (Breslau, 1845), Strack and Siegfried (Leipzig, 1884), and M. H. Segal's essay on the relation between Mishnic and Biblical Hebrew (*Jew. Quart. Rev.*, xx. 647–737); for Western Aramaic, especially G. Dalman, *Jüd. Pal. Aram.* (Leipzig, 1905); for Eastern Aram., S. D. Luzzatto (Eng. trans. by Goldammer, 1877), C. Levias (Cincinnati, 1900), M. L. Margolis (Munich, 1910), and also T. Nöldeke's *Mandäische Gramm.* (Halle, 1875).

The text of the Talmud has been badly preserved; much useful critical work has been done by R. Rabbinovicz, *Variae Lectiones* (Munich, 1876–86) for the Bab. T., and by B. Ratner, *Ahavath Zion* (in Heb., Wilna, 1901–2) for the Jer. T. As regards translations (a subject critically handled by E. Bischoff, Frankfort-on-Main, 1899) and texts, few are satisfactory; some have already been mentioned in § 1; for a full list see Strack's *Einleitung*, pp. 144–155. One may, however, mention the translations in English by D. A. de Sola and M. J. Raphall (18 Mishnic tractates; London 1843); J. Barclay (also a selection of 18; London, 1878), and the (abbreviated) edition of the Bab. Talm. with text and translation by M. L. Rodkinson (New York, 1869 sqq.). The Bab. text with a German translation has been edited by L. Goldschmidt (Berlin, 1897 sqq.). The Palest. Talm. has been translated into French by M. Schwab (Paris, 1871 sqq.).

5. *Features of Interest and Value.*—Although the Midrashim do not hold the authoritative position which the Talmud enjoys, the two groups cannot be kept apart in any consideration of the interesting or valuable features of the old Rabbinical writings. Viewed as a whole they have the characteristics of other Palestinian literature, the merits and defects of other oriental works. As regards the Talmud, neither the Mishnah nor the subsequent Gemara aimed at presenting a digested corpus of law. It is really a large collection of opinions and views, a remarkably heterogeneous mixture of contents, for which the history of its growth is no doubt largely responsible. It appals the reader with its irregularity of treatment, its variations of style, and its abrupt transitions from the spiritual to the crude and trivial, and from superstition to the purest insight. Like the Koran it is often concise to obscurity and cannot be translated literally;

[1] Lat. transl. of Orders I.–III., V., by Ugolinus, *Thes.*, xvii.–xx., recent ed. by M. S. Zuckermandel (Pasewalk, 1880); see *Jew. Ency.*, xii. 207 sqq.

[2] On the censorship and burning of the Talmud, see *Jew. Ency.*, iii. 642 sqq., xii. 22; Strack, 71 seq., 78 sqq.

[3] It is interesting to compare the development of Jewish law with that of the Mahommedan, Roman and English systems, the points of resemblance and difference being extremely suggestive for other studies. On the Jewish codifiers generally, see S. Daiches in L. Simon's *Aspects of Heb. Genius* (London, 1910), pp. 87 sqq.

it presupposes a knowledge which made commentaries a necessity even, as we have seen, to the Jews themselves. The opening of Order II. 6, for example, would be unintelligible without a knowledge of the law in Levit. xxiii. 42: "A booth (the interior of which is) about 20 cubits high is disallowed. R. Judah allows it. One which is not ten hands high, one which has not three walls, or which has more sun than shade is disallowed. 'An old booth?' (marks of quotation and interrogation must be supplied). The school of Shammai disallows it; but the school of Hillel allows it," &c. In the Gemara, the decisions of the Mishnah are not only discussed, explained or developed, but all kinds of additional matter are suggested by them. Thus, in the Bab. Gem. to III. 5, the reference in the Mishnah to the Zealots (Σικάριοι) is the occasion for a long romantic account of the wars preceding the destruction of the Second Temple. In IV. 3 the incidental prohibition of the cutting up of a roll of Scripture leads to a most valuable discussion of the arrangement of the Canon of the Old Testament, and other details including some account of the character and date of Job. There are numerous haggadic interpolations, some of considerable interest. Prose mingles with poetry, wit with wisdom, the good with the bad, and as one thing goes on to suggest another, it makes the Talmud a somewhat rambling compilation. It is scarcely a law-book or a work of divinity; it is almost an encyclopaedia in its scope, a store-house reproducing the knowledge and the thought, both unconscious and speculative, of the first few centuries of the Christian era.

A good idea of its heterogeneity is afforded by the English translations of Talmudic and other commentaries by P. I. Hershon (London, 1880–5). For miscellaneous collections of excerpts, see H. Polano (in the Chandos Classics); Chenery, *Legends from the Midrash*; I. Myers, *Gems from the Talmud*; S. Rapoport, *Tales and Maxims from the Midrash*; E. R. Montague, *Tales from the Talmud*. A valuable general introduction to the Rabbinical literature (with numerous excerpts) is given by J. Winter and A. Wünsche, *Gesch. d. Jüd.-Hellen. u. Talm. Litteratur* (Trier, 1894). The literature has not been fully explored for its contribution to the various branches of antiquarian research. On the animal fables, most of them found also in Indian and in classical collections, see J. Jacobs, *Fables of Aesop* (London, 1889); for myth, superstition and folk-lore, see D. Joel, *Aberglaube* (Breslau, 1881), and M. Grünbaum, *Semit. Sagenkunde* (Leiden, 1893), *Ges. Aufsätze* (Berlin, 1901); for mathematics, see B. Zuckermann (Breslau, 1878); for medicine, J. Bergel (Leipzig, 1885), &c. For these subjects, and for law, zoology, geography, &c. &c., see the full and classified bibliographies in M. L. Rodkinson, *Hist. of Talmud* (New York, 1903), vol. ii. ch. viii., and Strack's *Einleitung*, pp. 164–175.

Ordinary estimates of the Talmud are often influenced by the attitude of Christianity to Judaism and Jewish legalism, and by the preponderating interest which has been taken in the religious-legal side of the Rabbinical writings. The canonization of oral tradition in the Mishnah brought the advantages and the disadvantages of a legal religion, and controversialists have usually seen only one side. The excessive legalism which pervades the Talmud was the scholarship of the age, and the Talmud suffers to a certain extent because accepted opinions and isolated views are commingled. To those who have no patience with the minutiae of legislation, the prolix discussions are as irksome as the arguments appear arbitrary.[1] But the Talmudical discussions were often merely specialist and technical —they were academical and ecclesiastical debates which did not always touch every-day life; sometimes they were for the purpose of reconciling earlier conflicting views, or they even seem to be mere exhibitions of dialectic skill (cf., perhaps, Mk. xii. 18–23). It may be supposed that this predilection for casuistry stimulated that spirit which impelled Jewish scholars of the middle ages to study or translate the learning of the Greeks.[2] Once again it was—from a modern point of view—old-fashioned scholarship; yet one may now recognize that in the development of European science and philosophy it played a necessary part, and one can now realize that again the benefit was for common humanity rather than for the Jews alone. It may strike one as characteristically Jewish that extravagant and truly oriental encomiums were passed upon such legalists and Talmudists as Isaac Alfazi, Rashi or Maimonides; none the less the medieval Jews were able to produce and appreciate excellent literature of the most varied description. In any case, the Talmud must be judged, like other authoritative religious literature, by its place in history and by its survival. From age to age groups of laws were codified and expanded—the Priestly law of the Old Testament, the Mishnah, the complete Talmud, the subsequent codifications of Alfazi, Maimonides, and finally Joseph Caro. Thus, the Talmud occupies an intermediate place between the older sources and its later developments. At each step disintegration was arrested, but not Jewish genius; and the domination of the Law in Judaism did not as a matter of fact have the petrifying results which might have been anticipated. The explanation may be found partly in the intense feeling of solidarity uniting the Deity with his worshippers and his worshippers among themselves. No distinction was drawn between secular and religious duties, between ceremonial, ethical or spiritual requirements. Modern distinctions of moral and ceremonial being unknown, ancient systems must be judged in the light of those modes of thought which could not view religion apart from life. The Talmud discusses and formulates rules upon points which other religions leave to the individual; it inculcates both ceremonial and spiritual ideas, and often sets up most lofty ethical standards. The bonds, rigorous and strange as they often appear to others, were a sacrament enshrined in the imagination of the lowliest follower of the Talmud. Some of the keenest legalists (*e.g.* the Babylonian Rab) are famous for their ethical teaching, and for their share in popular exposition; one of the best ethical systems of medieval Judaism (by Baḥya ibn Pekuda) is founded upon the Talmud; the last exponent of Rabbinical legalism, Joseph Caro, was at the same time a mystic and a pietist; and the combination of the poetical with the legal temperament is frequent. The Talmud outlived the reactionary tendencies of the Qaraites (*q.v.*) and of the Kabbalah (*q.v.*), and fortunately, since these movements, important though they undoubtedly were for the evolution of thought, had not within them the power to be of lasting benefit to the rank and file of the community. Finally, no religion has been without exhibitions of fanaticism and excess on the part of its followers, and if the Old Testament itself was the authority for witch-burning among Christians, it is no longer profitable to ask whether the Talmud was responsible for offences committed by or alleged against those whose lives were regulated by it. On the other hand, Judaism has never been without its heroes, martyrs or saints, and the fact that it still lives is sufficient to prove that the mechanical legalism of the Talmud has not hindered the growth of Jewish religion.

Apart from the general interest of the literature for history and of its contents for various departments of research, the exegetical methods of the Talmud are especially instructive. There were rules of interpretation, and they give expression to one dominant idea: there is an infinite potentiality in the words of the Old Testament, none is fortuitous or meaningless or capable of only a single interpretation, they were said for all time, "for our sake also" and "for our learning" (cf. Paul, in Romans iv. 24, xv. 4). This was not conducive to *critical* inquiry; questions of the historical background of the biblical passage or of the trustworthiness of the text scarcely found a place. The interpretation itself is markedly subjective; by the side of much that is legitimate exegesis, there is much that appears arbitrary in the extreme. The endeavour was made to interpret, not necessarily according to the letter, but according to individual conceptions of the spirit and underlying motive. Thus, the same evidence could give rise to widely differing conflicting interpretations, which may not be directly deducible from or justified by the Scripture. Hence the value

[1] The whole subject of Jewish legalism should be compared with Islam, where again law and religion are one; as regards the legal aspect, see the extremely suggestive and instructive study, "The Relations of Law and Religion, the Mosque el-Azhar," by J. Bryce, *Studies in History and Jurisprudence* (1901), ii. No. xiii.

[2] Some of the most influential of the Greek works in the middle ages had passed through Syriac, Arabic and Hebrew translations before they appeared in their more familiar Latin dress!

of the teaching, whether halakic or haggadic, rests upon its intrinsic worth, and not upon the exegetical principles which were the tools common to the age. Moreover, it was also considered necessary that teaching should be authenticated, as it were, by its association with older authority whose standing guaranteed its genuineness. For this reason anonymous writings were attributed to famous names, and traditions were judged (as in Islam), not so much upon their merits, as by the chain of authorities which traced them back to their sources.

To supplement what has already been pointed out in the article MIDRASH, it may be noticed that the familiar penalty of the "forty stripes save one" (2 Cor. xi. 24; Josephus, *Ant.*, iv. 8, 23) is discussed in the Mishnah (*Makkoth*, iv. 5), and is subsequently explained by an extremely artificial interpretation of Deut. xxv. 2–3 (as though "to the number 40"). But the penalty is obviously older than, and entirely independent of, the arbitrary explanation by which it is supported. Again, the rending of clothes on the occasion of a charge of blasphemy (Matt. xxvi. 65) is actually connected with Joseph b. Qorha of the 2nd century A.D. (*Sanhed.*, vii. 5), although elsewhere this halakah is anonymous. Here the effort was made to substantiate a practice, but the tradition was not unanimous; and it often happens that the Talmud preserves different traditions regarding the same teaching, different versions of it, or it is ascribed to different authorities (see *Jew. Ency.*, xii. p. 15, col. 2). The fact that certain teaching is associated with a name may have no real significance for its antiquity, even as a law ascribed to the age of Moses—the recognized law-giver—may prove to be of much earlier or of much later inception. This feature naturally complicates all questions affecting origin and originality, and cannot be ignored in any study of the Talmud in its bearing upon the New Testament.[1] Similar or related forms of interpretation and teaching are found in the Talmud, in Hellenistic Judaism, in the New Testament, in early Church Fathers and in Syriac writers. As regards the New Testament itself, the points of similarity are many and often important. It has been asserted that "the writings of recent Jewish critics have tended on the whole to confirm the Gospel picture of external Jewish life, and where there is discrepancy these critics tend to prove that the blame lies not with the New Testament originals, but with their interpreters." The Talmud also makes "credible details which many Christian expositors have been rather inclined to dispute. Most remarkable of all has been the cumulative strength of the arguments adduced by Jewish writers favourable to the authenticity of the discourses in the Fourth Gospel . . ."[2] The points of contact between the phraseology in the Gospel of John and the early Midrashim are especially interesting.[3] The popularity of the parable as a form of didactic teaching finds many examples in the Rabbinical writings, and some have noteworthy parallels in the New testament.[4] It is known that there were theological controversies between Jews and Christians, and in the Midrash *Bereshith Rabbah* (MIDRASH, § 5, 5) is a passage (translated in *Jew. Ency.*, viii. 558) directed against the Christian view which found support for the doctrine of the Trinity in Gen. i. 26. But it is uncertain how far the doctrines of Judaism were influenced by Christianity, and it is even disputed whether the Talmud and Midrashim may be used to estimate Jewish thought of the 1st or 2nd century A.D. Much valuable work has been done by modern Jewish scholars on the "higher criticism" of these writings, which, it must be remembered, range over several centuries, but it still remains difficult to date their contents. Moreover, in endeavouring to sketch the theology of early Judaism it has been easy to find in the heterogeneous and conflicting ideas a system which agreed with preconceived views, and to reject as late or exceptional whatever told against them. In considering the evidence it is a delicate task to avoid confusing its meaning for its age with that which has appeared the only natural or appropriate one to subsequent interpreters (whether Jewish or Christian) who have been necessarily influenced by their environment and by contemporary thought. At all events, if these writings have many old elements and may be used to illustrate the background of the New Testament, they illustrate not only the excessive legalism and ritualism against which early Christianity contended, but also the more spiritual and ethical side of Judaism. Upon this latter phase the pseudepigraphical and apocalyptical writings have shed much unexpected light in linking the Old Testament with both Christian and Rabbinical theology. The various problems which arise are still under discussion, and are of great importance for the study of Palestinian thought at the age of the parting of the ways. They touch, on the one hand, the absolute originality of Christianity and its attitude to Jewish legalism, and, on the other, the true place of the *pseudepigrapha* in Jewish thought and the antiquity of the Judaism which dominates the Talmud. They do not, however, exclude the possibility that by the side of the scholasticism of the early Jewish academical circles was the more popular thought which, forming a link between Jews and Christians, ultimately fell into neglect as Judaism and Christianity formulated their theologies.

On the close relation between the thought of the age, see B. Ritter, *Philo u. d. Halacha* (Leipzig, 1879); M. Grünwald in Königsberger's *Monatsblätter* (Berlin, 1890); N. I. Weinstein, *Zur Genesis d. Agada* (Frankfort-on-Main, 1901); W. Bousset, *Relig. d. Judentums*, pp. 50 sqq.; R. Graffin's ed. of Aphraates (*q.v.*) (Paris, 1894), p. xlix. seq.; S. Funk on the haggadic elements in Aphraates (Vienna, 1891); and art. MIDRASH, § 4. In this respect the pseudepigraphic lit. is frequently of the greatest interest; thus Mark. iv. 24 finds a close parallel in "the Testament of Zebulun," viii. 3 (R. H. Charles, *Test. of xii. Patriarchs*, p. 117), and does not differ essentially from the saying ascribed to Gamaliel II. (*Shabb.* 51*b*) and others. A close parallel to Matt. vii. 3 is ascribed to R. Tarpon, latter half of 1st century A.D. (*Arak.* 16*b*: "If one says, take the mote from thy eye, he answers, take the beam from thy eye"); it seems to have been a popular saying (see *Baba Bathra*, 15*b*). See further, for the Talmud and Midrashim in relation to the New Testament generally, the literature in Strack, pp. 165 sqq.; also A. Wünsche, *Neue Beiträge z. Erläut. d. Evangelien* (Göttingen, 1878); C. H. Toy, *Judaism and Christianity* (London, 1890; with Schechter's essay in his *Studies* [1896], pp. 283–305); H. Laible, *Jesus Christus im Talmud* (Berlin, 1891); R. T. Herford, *Christianity in Talmud and Midrash* (London, 1903; with W. Bacher's review in *Jew. Quart. Rev.*, xvii. 171–183); Bousset, *op. cit.*; Oesterley and Box, *op. cit.* (with C. G. Montefiore's review in *Jew. Quart. Rev.*, 1908, pp. 347–357); I. Abrahams in Swete's *Camb. Bibl. Essays* (1909), pp. 163–192; C. G. Montefiore, *Synoptic Gospels* (1909); H. L. Strack, *Jesus, die Häretiker u. die Christen* (1910).

Results of criticism.

The Talmud itself is still the authoritative and practical guide of the great mass of the Jews, and is too closely connected with contemporary and earlier Palestinian history to be neglected by Christians. With the progress of modern research the value of this and of the other old Rabbinical writings is being re-estimated, and criticism has forced a modification of many old views.[5] Thus, an early reference to the *title* of a work does not prove that it is that which is now current; this applies, for example, to the tractate ʿ*Ēduyyōth* (see *Jew. Ency.*, viii. 611), and to the Midrash *Siphrē*, which frequently differs from that as known to the Talmud (*ib.*, xi. 331). It has been found that a tradition, however

[1] There are many details in the Talmud which cannot be dated; if some are obviously contemporary, others find parallels in Ancient Babylonia, for example in the code of Hammurabi. See L. N. Dembitz, *Jew. Quart. Rev.*, xix. 109–126, and the literature on the code (see BABYLONIAN LAW). Numerous miscellaneous examples of the intimate relationship between the Rabbinical and older oriental material will be found in H. Pick, *Assyrisches u. Talmudisches* (Berlin, 1903); A. Jeremias, *Bab. im N. Test.* (Leipzig, 1905), *Alte Test. im Lichte d. Alten Orients* (*ib.*, 1906); E. Bischoff, *Bab. astrales im Weltbilde d. Thalmud u. Midrasch* (*ib.*, 1907).

[2] I. Abrahams, on "Rabbinic Aids to Exegesis," in Swete's *Camb. Bibl. Essays* (1909), p. 181.

[3] See the essay of Schlatter, *Sprache u. Heimat d. vierten Evangelisten* (1902).

[4] See P. Fiebig, *Alt-jüd. Gleichnisse u. d. Gleichnisse Jesu* (Leipzig, 1904); Lauterbach, *Jew. Ency.*, ix. 512 sqq.; Oesterley and Box, p. 96 seq.

[5] The "higher criticism" of these writings affords many useful hints and suggestions for that of other composite works, *e.g.* the Old Testament. It may be noticed also that the references to the Old Testament sometimes represent a slightly divergent text; see V. A. Aptowitzer, *Schriftwort in d. Rabb. Lit.* (1906); I. Abrahams, *Camb. Bibl. Essays*, pp. 172 sqq.

tenacious or circumstantial, is not necessarily genuine, and that too in spite of the chain of authorities by which its antiquity or genuineness appeared to be confirmed. Implicit reliance can no longer be necessarily placed upon the reputed authorship or editorship of a work; yet, although many of the views of medieval Jews in this respect prove to be erroneous (*e.g.* on the authorship of the Zōhar; see KABBALAH), they may sometimes preserve the recollection of a fact which only needs restatement (*e.g.* R. Johanan as the editor of the Pal. Talmud).

Finally, the Talmud comes at the end of a very lengthy development of Palestinian thought (see PALESTINE: *History*). It is in the direct line of descent from the Old Testament—intervening literature having been lost—the essence of which it makes its own. Forced by the events of history, this legacy of the past was subjected to successive processes and adapted to the needs of successive generations and of widely different historical and social conditions. Legal compendiums and systems of philosophy served their age and gave place to later developments; and the elasticity of interpretation which characterizes it enabled it to outlive Karaites and Kabbalists. It also escaped the classicism of the Renaissance with its insistence upon the test—*either* fact *or* fiction. As an oriental work among an oriental people the moral and spiritual influence of the Talmud has rested upon its connexion with a history which appealed to the imagination and the feelings, upon its heterogeneity of contents suitable for all moods and minds, and upon the unifying and regulative effects of its legalism. The relationship of Talmudism to the Old Testament has been likened to that of Christian theology to the Gospels; the comparison, whether fitting or not, may at least enable one to understand the varying attitudes of Jewish thinkers to their ancient sources. With closer contact to the un-oriental West and with the inevitable tendencies of modern western scholarship the Talmud has entered upon a new period, one which, though it may be said to date from the time of Moses Mendelssohn (see JEWS, § 48), has reached a more distinctive stage at the present day. In the weakening of that authority which had been ascribed almost unanimously to the Talmud, and invariably to the Old Testament, a new and greater strain has been laid upon Judaism to reinterpret its spirit once more to answer the diverse wants of its adherents. This is part of that larger and pressing psychological problem of adjusting the "authority" ascribed to past writings to that of the collective human experience; it does not confront Judaism alone, and it must suffice to refer to the writings of "Reformed Judaism"; see, *e.g.* C. G. Montefiore, *Liberal Judaism* (London, 1903); *Truth in Religion* (1906); I. Abrahams, *Judaism* (1907), and the essays of S. Schechter.

Reformed Judaism.

BIBLIOGRAPHY.—E. Deutsch's article on the Talmud in the *Quarterly Review*, Oct. 1867 (reprinted in his *Literary Remains*), is noteworthy for the great interest it aroused. For other introductions, see S. Schiller-Szinessy, articles "Midrash," "Mishnah," and "Talmud," in *Ency. Brit.*, 9th ed.; J. Z. Lauterbach, "Mishnah," and W. Bacher, "Talmud" in the *Jew. Ency.*; S. Schechter, "Talmud," in Hastings' *Dict. Bib.*, vol. v.; and also S. Funk, *Entstehung des Talmuds* (Leipzig, 1910). More comprehensive are the handbooks of M. Mielziner, *Introd. to the Talmud* (Cincinnati, 1894), M. L. Rodkinson, *History of the Talmud* (New York, 1903), and especially H. L. Strack, *Einleitung in den Talmud* (Leipzig, 1908, very concise, but replete with bibliographical and other information). The works already cited in this article or in the art. MIDRASH, cover the most important departments of the Rabbinical literature, and may be supplemented from the critical Jewish journals, *e.g.* the *Jewish Quarterly Review*, *Revue des Études Juives* (Paris), and especially the *Monatsschrift f. Gesch. u. Wissenschaft des Judentums* (Breslau).

The writer desires to express his indebtedness to Mr Israel Abrahams for bibliographical and other suggestions. (S. A. C.)

TALUKDAR (Hind. from *talūk*, district, and *dār*, holding), the name of (1) an official in the state of Hyderabad, India, equivalent to magistrate and collector, and (2) a landholder with peculiar tenures in various parts of India, particularly in Oude (see UNITED PROVINCES).

TALUS (Lat. for the "ankle-bone"), in architecture, the slope of an embankment wall, which is thicker at the bottom than at the top, to resist the pressure of the earth behind it.

TAM, JACOB BEN MEÏR (1100–1171), a grandson of Rashi (*q.v.*), was the most famous French glossator (*tosafist*) on the text of the Talmud. In 1147 he was attacked and injured by a disorderly band who had attached themselves to the Crusaders. He escaped to the neighbouring Troyes, where about 1160 was held the first of the Jewish Synods, for which the Rhinelands became celebrated. At this meeting it was laid down that disputes between Jew and Jew were not to be carried to a Christian court, but were to be settled by fraternal arbitration. New conditions of life had arisen owing to the closer terms on which Jews and Christians lived, and Jacob Tam was foremost in settling the terms which were to govern the relations, from the Jewish side. Many others of his practical ordinances (*Takkanoth*), connected with marriage and divorce, trade and proselytism, as well as with synagogue ritual, had abiding influence, and bear invariably the stamp of enlightened independence within the limits of recognized authoritative tradition and law. Of his legal work the most important was collected in his *Sefer ha-yashar*. He was also a poet and grammarian.

See Gross, *Gallia Judaica* (index); M. Schloessinger in *Jewish Encyclopedia*, vii. 36–39. (I. A.)

TAMAQUA, a borough of Schuylkill county, Pennsylvania, U.S.A., on the Tamaqua (Little Schuylkill) river, about 20 m. above its junction with the Schuylkill, about 17 m. E.N.E. of Pottsville, and about 98 m. N. of Philadelphia. Pop. (1890) 6054; (1900) 7267, (625 foreign-born); (1910) 9462. Tamaqua is served by the Central railroad of New Jersey, by the Philadelphia and Reading railway and by an electric line connecting with Mauch Chunk, Pottsville, and other places. Tamaqua is in a rich anthracite coal district, and coal-mining is its chief industry. Among manufactures are foundry and machine-shop products, powder, stoves, furniture, hosiery, &c. The borough owns the water-works. The first settlement here was made in 1799 and anthracite coal was discovered in 1817. In 1829 Tamaqua was laid out and received its present name, an Indian word meaning "running water." It was incorporated as a borough in 1833. Between 1869 and 1875 the Molly Maguires were active here.

TAMARIND. This name is popularly applied to the pods of a leguminous tree, which are hard externally, but within filled with an acid juicy pulp containing sugar and various acids, such as citric and tartaric, in combination with potash. The acid pulp is used as a laxative and a refrigerant, the pods being largely imported both from the East and the West Indies. The tree is now widely distributed in tropical countries, but it is generally considered that its native country is in eastern tropical Africa, from Abyssinia southward to the Zambezi. The name (meaning in Arabic "Indian date") shows that it entered medieval commerce from India, where it is used, not only for its pulp, but for its seeds, which are astringent, its leaves, which furnish a yellow or a red dye, and its timber. The tree (*Tamarindus indica*) attains a height of 70 to 80 ft., and bears elegant pinnate foliage and purplish or orange veined flowers arranged in terminal racemes. The flower-tube bears at its summit four sepals, but only three petals and three perfect stamens, with indications of six others. The stamens, with the stalked ovary, are curved away from the petals at their base, but are directed towards them at their apices. The anthers and the stigmas are thus brought into such a position as to obstruct the passage of an insect attracted by the brilliantly-coloured petal, the inference of course being that insect visits are necessary for transference of pollen and the fertilization of the flower.

TAMARISK. The genus *Tamarix* gives its name to a small group of shrubs or low trees constituting the tamarisk family Tamaricaceae. The species of tamarisk and of the very closely allied genus *Myricaria* grow in salt-deserts, by the sea-shore, or in other more or less sterile localities in warm, temperate, subtropical, and tropical regions of the eastern hemisphere. Their long slender branches bear very numerous small appressed leaves, in which the evaporating surface is reduced to a minimum. The flowers are minute and numerous, in long clusters at the ends of the branches or from the trunk. Each has 4–5 free sepals, and as many petals springing with the 4–10 stamens from a fleshy disk. In *Tamarix* the stamens are free, while in *Myricaria* they are united into one parcel. The free ovary is one-celled, with basal placentas, and surmounted by 3–5 styles. The fruit is capsular, and contains numerous seeds, each usually with a long tuft of hairs at one end. The great value of these shrubs or trees lies in their ability to withstand the effects of drought and a saline soil, in consequence of which they grow where little else can flourish. On this account the common tamarisk, *T. gallica*, is planted on sea-coasts, and affords shelter where none other could be provided. Some species produce galls, valued for their tannin, while the astringent bark of others has occasionally been used for medicinal purposes. The ashes of the plant, when grown near the sea, are said to contain soda. For tamarisk manna, see MANNA.

TAMATAVE (called by the natives *Tòamàsina*), the chief seaport of Madagascar, situated nearly on the centre of the eastern coast in 18° 10′ S., 49° 32′ E. It owes its importance to the existence of a coral reef, which forms a spacious and fairly commodious harbour, entered by two openings. The town is built on a sandy peninsula which projects at right angles from the general coast-line. On this are crowded together a considerable number of houses, with good shops and merchants' offices in the main thoroughfares. Tamatave is the seat of several foreign consuls, as well as of numerous French officials, and is the chief port for the capital and the interior. Imports consist principally of piece-goods, farinaceous foods, and iron and steel goods, and exports of gold dust, raffia, hides, caoutchouc and live animals. Communication with Europe is maintained by steamers of the Messageries Maritimes and the Havraise companies, and also with Mauritius, and from thence to Ceylon, by the British Union-Castle line. Of the whole foreign trade of Madagascar, 46 per cent. is through Tamatave. Owing to the character of the soil and the formerly crowded native population, the town has often been attacked by epidemics: the plague broke out in 1898, and again in 1900; but since the draining of the neighbouring marshes, there has been improvement. Since 1895 the native population has been removed from the town and settled in a new village to the north-west. A telegraph, 180 miles in length, connects Tamatave with the capital. There is also a service, partly by railway and partly by steamer, along the coast lagoons, connecting the port with Antanànarìvo. Pop. about 4600.

TAMAULIPAS, a northern Gulf-coast state of Mexico, bounded N. by Texas, U.S.A., E. by the Gulf of Mexico, S.E. by Vera Cruz, S. by San Luis Potosi, W. by Nuevo Leon, and N.W. by Coahuila. Area 32,128 sq. m. Pop. (1900) 218,948. The central and southern parts of the state are mountainous, but there are extensive fertile plains in the N. sloping gently N.E. toward the Rio Grande, and the coastal zone is sandy, much broken by lagoons and uninhabited. Except in the N. this coastal zone is only 5 to 7 m. wide, but the foothills region back of this is usually well wooded and fertile, and the low alluvial river valleys penetrate deeply into the sierras. There are four navigable rivers in the state—the Rio Grande del Norte, or Rio Bravo, which forms the boundary line with the United States, the Conchas or Presas, the Soto da Marina, and the Tamesi. The Panuco forms the southern boundary for a short distance. A peculiar feature of the hydrography of Tamaulipas is the series of coastal lagoons formed by the building of new beaches across the indentations of the coast. The largest of these is the Laguna de la Madre, 125 m. long, which receives the waters of the Rio Conchas, and is separated in places from the Gulf by only a narrow ridge of sand dunes. The climate is hot, humid and malarial on the coast, but is pleasant on the more elevated lands of the interior. On the plains bordering the Rio Grande frosts are frequent. The rainfall is abundant, especially on the mountain slopes of the south. The principal industry is agriculture. Sugar, cereals, tobacco, cotton and coffee are produced, and probably fruit may be raised successfully. Stock-raising receives some attention and hides and cattle are exported. The preparation of ixtle fibre for export is becoming an important industry. Copper is mined and extensive deposits of petroleum and asphalt are being exploited. Railway communication is provided by the Mexican National which crosses the northern end of the state, the Belgian line from Monterrey to Tampico, and a branch of the Mexican Central from San Luis Potosi to Tampico.

The capital of Tamaulipas is Ciudad Victoria (pop. in 1900, 10,086), a small sierra town on the Monterrey and Tampico railway about 120 m. from Tampico. Its public buildings are good and it has the improvements of a modern town. It has a fine climate, a good trade, and is a summer resort for residents of the coast. The city is near the Rio Santander, and was once called Nuevo Santander. Among other towns in the state may be mentioned: Matamoros (*q.v.*), on the Rio Grande; Tampico (*q.v.*), on the Panuco, the principal port of the state; Tula (6935 in 1900); Jaumave (about 10,000 in 1900, chiefly Indians), 38 m. S.W. of Ciudad Victoria, in the heart of a prominent ixtle-producing region; Mier (7114 in 1895), on the Rio Grande, 95 m. E.N.E. of Monterrey; San Carlos (6871 in 1895), 57 m. N.E. of the capital; Camargo (6815 in 1895), on the San Juan near the Rio Grande, once the old Spanish mission of San Augustin Laredo; and Reynosa (6137 in 1895), 54 m. W.N.W. of Matamoros.

TAMAYO Y BAUS, MANUEL (1829–1898), Spanish dramatist, was born at Madrid on the 15th of September 1829. He came of a family connected with the theatre, his mother being the eminent actress Joaquina Baus. It is interesting to note that she appeared as Geneviève de Brabant in an arrangement from the French made by Tamayo when he was in his twelfth year. Through the influence of his uncle, Antonio Gil y Zárate, minister of education, Tamayo's independence was secured by his nomination to a post in a government office. The earliest of his printed pieces, *Juana de Arco* (1847), is an arrangement from Schiller, and *Una Aventura de Richelieu*, which the author has not cared to preserve, is said to be an imitation of Alexandre Duval. The general idea of his *Angela* (1852) was derived from Schiller's *Kabale und Liebe*, but the atmosphere is Spanish, the situations are original, and the phrasing is Tamayo's own. His first great success was *Virginia* (1853), a dramatic essay in Alfieri's manner, remarkable for its ingenuity and noble diction. In 1854 Tamayo was expelled from his post by the new Liberal government, but was restored before long by Cándido Nocedal, a minister who had been struck by the young man's talent. He collaborated with Aureliano Fernández-Guerra y Orbe in writing *La Ricahembra* (1854), a historical drama which recalls the vigour of Lope de Vega. *La Locura de Amor* (1855), in which Juana *la loca*, the passionate, love-sick daughter of Isabel the Catholic, figures as the chief personage, established Tamayo's reputation as Spain's leading playwright. *Hija y Madre* (1855) is a failure, and *La Bola de Nieve* (1856) is notable solely for its excellent workmanship. It is unfortunate that Tamayo's straitened means forced him to put original work aside and to adapt pieces from the French. Examples of this sort are fairly numerous. *Lo Positivo* (1862), imitated from Adrien-Augustin-Léon Laya's *Duc Job*, is well-nigh forgotten, though the Spanish version is a dexterous piece of stagecraft and contains some elements of original value. *Del dicho al hecho* (1864) is from *La Pierre de touche* of Jules Sandeau and Émile Augier, and a pleasing proverb, *Más vale Maña que Fuerza* (1866) is a great improvement upon Mme Caroline Berton's *Diplomatie du Ménage*. The revolution of 1868, which cost Tamayo his post at the San Isidro Library, is indirectly responsible for *No hay mal que por bien no venga* (1868), a clever arrangement of *Le Feu au Couvent*, by Henri Murger's friend, Théodore Barrière. During these seven years Tamayo produced only one original piece, *Lances de Honor* (1863), which turned upon the immorality of duelling, and led to a warm discussion among the public. Written in prose, the piece is inspired by a breath of medieval piety which had not been felt in the Spanish theatre since the 17th century. This renascence of an old-world motive has induced many critics to consider *Lances de Honor* as Tamayo's best work, but that distinction should be accorded rather to *Un Drama nuevo* (1867), a play in which the author has ventured to place Shakespeare and Yorick upon the scene. *Los Hombres de bien* (1870) was

Tamayo's final contribution to the Spanish stage. His last years were spent in recasting his *Virginia*, and the result of his efforts may be read in the posthumous edition of his *Obras* (Madrid, 1898–99). In 1858 Tamayo was elected a member of the Spanish Academy, to which he afterwards became permanent secretary; and in 1884 the Conservative minister, Alejandro Pidal y Mon, appointed him director of the National Library. He died on the 20th of June 1898. (J. F.-K.)

TAMBOUR (Fr. for "drum"), the term in architecture given to the inverted bell of a Corinthian capital round which were carved the acanthus leaves decorating it: applied also to the wall of a circular structure, whether on the ground or raised aloft on pendentives and carrying a dome; and to the drum of a column which is built in several courses.

TAMBOURINE (Fr. *tambour de Basque*; Ger. *baskische Trommel*, *Tambourin*, or *Schellen-trommel*), a popular instrument of percussion of indefinite musical pitch, used for marking the rhythm in dance or bacchanalian music. The tambourine consists of a flat wooden or metal ring, over one end of which is stretched a parchment or vellum head; in the circumference of the ring are fixed nine or ten metal disks or small bells which jingle as the tambourine is struck by the hand, or merely waved through the air. A tremolo effect is obtained by stroking the head with the finger-tips. In a 14th-century MS. (Brit. Mus. Sloane 3983, fol. 13) a tambourine of modern appearance with a snare bears the inscription "Tympanum." The tambourine is of the highest antiquity, and was known at different times under the names of *timbrel* or *tabret*, *tympanon* or *tympanum*, and *symphonia*. (K. S.)

TAMBOV, one of the largest and most fertile governments of central Russia, extending from N. to S. between the basins of the Oka and the Don, and having the governments of Vladimir and Nizhniy-Novgorod on the N., Penza and Saratov on the E., Voronezh on the S., and Orel, Tula and Ryazan on the W. It has an area of 25,703 sq. m., and consists of an undulating plain intersected by deep ravines and broad valleys, ranging 450 to 800 ft. above sea-level. Cretaceous and Jurassic deposits, thickly covered with boulder-clay and loess, are widely spread over its surface, concealing the underlying Devonian and Carboniferous strata. These last crop out in the deeper ravines, and seams of coal have been noticed at several places. Iron ore (in the north-west), limestone, clay and gypsum are obtained, and traces of petroleum have been discovered. The mineral waters of Lipetsk, similar to those of Franzensbad in their alkaline elements, and chalybeate like those of Pyrmont and Spa, are well known in Russia. The Oka touches the north-west corner of the government, but its tributaries, the Moksha and the Tsna, are important channels of traffic. The Don also merely touches Tambov, and of its affluents none except the Voronezh and the Khoper and the Vorona, a tributary of the Khoper, are at all navigable. As a whole, it is only in the north that Tambov is well drained; in the south, which is exposed to the dry south-east winds, the want of moisture is much felt, especially in the district of Borisoglyebsk. The climate is continental, and, although the average temperature at Tambov is 42° F., the winter is comparatively cold (January, 13°; July, 68°). The rivers remain frozen for four months and a half. Forests occupy about 7½ per cent. of the total area, and occur chiefly in the west; in the south-east wood is scarce, and straw is used for fuel. The soil is fertile throughout; in the north it is clayey and sometimes sandy, but the rest of the government is covered with a sheet, 2 to 3 feet thick, of black earth, of such richness that in Borisoglyebsk cornfields which have not been manured for eighty years still yield good crops.

The estimated population in 1906 was 3,205,200. The government is divided into twelve districts, the chief towns of which are Tambov, Borisoglyebsk, Yelatma, Kirsanov, Kozlov, Lebedyan, Lipetsk, Morshansk, Shatsk, Spask, Temnikov and Usman. The inhabitants are Great Russians in the centre, but there is a notable admixture of Mordvinians and Meshcheryaks in the west and north-west, as also of Tatars. The Mordvinians are rapidly becoming Russified. Nonconformity has a relatively strong hold in the government. Notwithstanding a high birth-rate (45 in the thousand), the annual increase of population is but slow (0·5 per cent. annually). The prevailing occupation is agriculture, modern machinery being used on the steppe farms. More than two-thirds of the area is arable, and of this proportion 53 per cent. belongs to the peasant communities, 36 per cent. to private individuals, and 11 per cent. to the crown. The principal crops are rye, wheat, oats, barley and potatoes. Grain is exported to a considerable extent from the south, although the yield is deficient in the north. Hemp and linseed are also cultivated, and the production of tobacco is yearly increasing. Beetroot is extensively grown for sugar. Live-stock breeding, though less extensively carried on than formerly, is still important. Excellent breeds of horses are met with, not only on the larger estates, but also in the hands of the wealthier peasants, those of the Bityug river being most esteemed. Manufacturers are represented chiefly by distilleries, tallow-melting works, sugar factories, flour-mills and woollen-cloth mills. Commerce is brisk, owing to the large grain export—Kozlov, Morshansk, Tambov and Borisoglyebsk being the chief centres for this traffic, and Lebedyan for the trade in horses and cattle. This government is backward educationally. A distinctive feature is its large villages of crown peasants.

The region now included in the north of the government was settled by Russians during the earliest centuries of the principality of Moscow, but until the end of the 17th century the fertile tracts in the south remained too insecure for settlers. In the following century a few immigrants began to come in from the steppe, and landowners who had received large grants of land from the tsars began to bring their serfs from central Russia. (P. A. K.; J. T. Be.)

TAMBOV, a town of Russia, capital of the government of the same name, 300 m. by rail S.E. from Moscow, on the Tsna river, and on the railway to Saratov. Pop. (1884) 34,000; (1900) 49,208. The town is almost entirely built of wood, with broad unpaved streets, lined with low houses surrounded by gardens; but it is an archiepiscopal see of the Orthodox Greek Church. Woollens, tobacco, oil and various other commodities are manufactured. The trade in grain, and in cattle purchased in the south and sent to Moscow, is far less important than that of Morshansk and Kozlov.

TAMBURELLO (called in Piedmont *Tabasso*), a court game popular in Italy, particularly in the northern provinces. It is a modification of the ancient game of *Pallone* (*q.v.*), bearing the same general relation to it as Squash does to Racquets. A full-sized Tamburello Court, which need not be as true and even as that for Pallone, is 90 to 100 yards long and half as wide, divided laterally through the middle by a line (*cordino*) into two equal spaces, the *battuta* and the *rimessa*. Three players regularly form a side, each carrying in one hand an implement called *tamburello*, resembling a tambourine (whence the name), which is a round frame of wood upon which is tightly stretched a cover of horse-hide. A rubber ball about the size of a lawn-tennis ball is used. One of the players opens the service (*battuta*), which is made from a small square called the *trampolino*, situated at one corner of the *battuta* but outside the court. The service must be over the middle line. The ball must then be hit from side to side over the line, the side failing to return it or sending it out of court losing a point. The game is scored like lawn-tennis, four points constituting a game, counting 15+15+10+10. Tamburello, a less expensive game than Pallone, is popular with the lower classes, who use it as a medium for betting.

TAMILS. The word *Tamil* (properly *Tamiḻ*) has been identified with Draviḍa, the Sanskrit generic appellation for the south Indian peoples and their languages; and the various stages through which the word has passed—Dramiḍa, Dramila, Damila—have been finally discussed by Bishop Caldwell in his *Comparative Grammar of the Dravidian Languages* (2d ed., 1875, p. 10 seq.). The identification was first suggested by Dr Graul (*Reise nach Ostindien*, vol. iii., 1854, p. 349), and then adverted to by Dr G. U. Pope (*Tamil Handbook*, 1859, Introduction) and Dr Gundert (*Malayâḻma Dictionary*, 1872, *s.v.*). Dr Pope, however, believed Tamiḷ to be a corruption of *tenmoli*, southern speech, in contradistinction to *vaḍugu*, the northern, *i.e.*, Telugu language. As in the case of the Kafir, Turkish, Tagala and other typical languages, the term Tamulic or Tamulian has occasionally been employed as the designation of the whole class of Dravidian peoples and languages, of which it is only the most prominent member. The present article deals with Tamil in its restricted sense only. The Tamils proper are smaller and of weaker build than Europeans, though graceful in shape. Their physical appearance is described as follows:—a pointed and frequently hooked pyramidal nose, with conspicuous nares, more long than round; a marked sinking in of the orbital line, producing a strongly defined orbital ridge; hair and eyes black; the latter, varying from small to middle-sized, have a peculiar sparkle and a look of calculation; mouth large, lips thick, lower jaw not heavy; forehead well-formed, but receding, inclining to flattish, and seldom high; beard considerable, and often strong; colour of skin very dark, frequently approaching to black (*Manual of the Administration of the Madras Presidency*, Madras, 1885, vol. i., Introd., p. 36; see also Caldwell, *Comparative Grammar of the Dravidian Languages*, 1875, pp. 558–79). The Tamils have many good qualities—frugality, patience, endurance, politeness—and they are credited with astounding memories; their worst vices are said to be lying and lasciviousness. Of all the South-Indian tribes they are the least sedentary and the most enterprising. Wherever money is to be earned, there will Tamils be found, either as merchants or in the lower capacity of domestic servants and labourers. The tea and coffee districts of Ceylon are peopled by about 950,000; Tamils serve as coolies in the Mauritius and the West Indies; in Burma, the Straits, and Siam the so-called Klings are all Tamils (Graul, *Reise nach Ostindien*, Leipzig, 1855, vol. iv. pp. 113–212).

Language.—The area over which Tamil is spoken extends from a few miles north of the city of Madras to the extreme south of the eastern side of the peninsula, throughout the country below the Eastern Ghats, from Pulicat to Cape Comorin, and from the Ghats to the Bay of Bengal, including also the southern portion of Travancore on the western side of the Ghats and the northern part of Ceylon. According to the census of 1901, the total number of Tamil-speaking people in all India was 16,525,500. To these should be added about 160,000 in the French possessions. But as of all the Dravidian languages the Tamil shows the greatest tendency to spread, its area becomes ever larger, encroaching on that of the contiguous languages. Tamil is a sister of Malayâḷam, Telugu, Kanarese, Tulu; and, as it is the oldest, richest, and most highly organized of the Dravidian languages, it may be looked upon as typical of the family to which it belongs. The one nearest akin to it is Malayâḷam, which originally appears to have been simply a dialect of Tamil, but differs from it now both in pronunciation and in idiom, in the retention of old Tamil forms obsolete in the modern language, and in having discarded all personal terminations in the verb, the person being always indicated by the pronoun (F. W. Ellis, *Dissertation on the Malayâḷam Language*, p. 2; Gundert, *Malayâḷma Dictionary*, Introd.; Caldwell, *Comparative Gr.*, Introd., p. 23; Burnell, *Specimens of South Indian Dialects*, No. 2, p. 13). Also, the proportion of Sanskrit words in Malayâḷam is greater, while in Tamil it is less, than in any other Dravidian tongue. This divergence between the two languages cannot be traced farther back than about the 10th century; for, as it appears from the Cochin and Travancore inscriptions, previous to that period both languages were still substantially identical; whereas in the *Râmacharitam*, the oldest poem in Malayâḷam, composed probably in the 13th century, at any rate long before the arrival of the Portuguese and the introduction of the modern character, we see that language already formed. The modern Tamil characters originated "in a Brahmanical adaptation of the old Grantha letters corresponding to the so-called Vaṭṭeḷuttu," or round-hand, an alphabet once in vogue throughout the whole of the Pâṇḍyan kingdom, as well as in the South Malabar and Coimbatore districts, and still sparsely used for drawing up conveyances and other legal instruments (F. W. Ellis, *Dissertation*, p. 3). It is also used by the Moplahs in Tellicherry. The origin of the Vaṭṭeḷuttu itself is still a controverted question. Dr Burnell, the greatest authority on the subject, stated his reasons for tracing that character through the Pahlavi to a Semitic source (*Elements of South Indian Palaeography*, 2nd ed., 1878, pp. 47–52, and plates xvii. and xxxii.). In the 8th century the Vaṭṭeḷuttu existed side by side and together with the Grantha, an ancient alphabet still used throughout the Tamil country in writing Sanskrit. During the four or five centuries after the conquest of Madura by the Cholas in the 11th it was gradually superseded in the Tamil country by the modern Tamil, while in Malabar it continued in general use down to the end of the 17th century. But the earliest works of Tamil literature, such as the *Tolkâppiyam* and the *Kuṛaḷ*, were still written in it. The modern Tamil characters, which have but little changed for the last 500 years, differ from all the other modern Dravidian alphabets both in shape and in their phonetic value. Their angular form is said to be due to the widespread practice of writing with the style resting on the *end* of the left thumb-nail, while the other alphabets are written with the style resting on the left side of the thumb.

The Tamil alphabet is sufficiently well adapted for the expression of the twelve vowels of the language (*a, â, i, î, u, û, e, ê, o, ô, ei, au*), —the occasional sounds of *ö* and *ü*, both short and long, being covered by the signs for *e, ê, i, î*; but it is utterly inadequate for the proper expression of the consonants, inasmuch as the one character *k* has to do duty also for *kh, g, gh*, and similarly each of the other surd consonants *ch, ṭ, t, p* represents also the remaining three letters of its respective class. The letter *k* has, besides, occasionally the sound of *h*, and *ch* that of *s*. Each of the five consonants *k, ch, ṭ, t, p* has its own nasal. In addition to the four semivowels, the Tamil possesses a cerebral *ṛ* and *ḷ*, and has, in common with the Malayâḷam, retained a liquid *ḻ*, once peculiar to all the Dravidian languages, the sound of which is so difficult to fix graphically, and varies so much in different districts, that it has been rendered in a dozen different ways (*Manual of the Administration of the Madras Presidency*, vol. ii. pp. 20 seq.). Fr. Müller is probably correct in approximating it to that of the Bohemian *ř*. There is, lastly, a peculiar *n*, differing in function but not in pronunciation from the dental *n*. The three sibilants and *ḥ* of Sanskrit have no place in the Tamil alphabet; but *ch* often does duty as a sibilant in writing foreign words, and the four corresponding letters as well as *j* and *ksh* of the Grantha alphabet are now frequently called to aid. It is obvious that many of the Sanskrit words imported into Tamil at various periods (Caldwell, *loc. cit.*, Introd., pp. 86 seq.) have, in consequence of the incongruity of the Sanskrit and Tamil notation of their respective phonetic systems, assumed disguises under which the original is scarcely recognizable: examples are *ulagu* (loka), *uruvam* (rûpa), *arukken* (arka), *aṛputam* (adbhutam), *naṭchattiram* (nakshatram), *iruḍi* (rishi), *tîrkam* (dîrgha), *arasen* (râjan). Besides the Sanskrit ingredients, which appear but sparsely in the old poetry, Tamil has borrowed from Hindustani, Arabic, and Persian a large number of revenue, political, and judicial terms, and more recently a good many English words have crept in, such as *tiraṭṭi*, treaty, *paṭlar*, butler, *âkṭ*, act, *kulôb*, club, *kavarnar*, governor, *pinalkôdu*, penal code, *sîkku*, sick, *mejastiraṭṭu*, magistrate. But, as compared with its literary sister languages, it has preserved its Dravidian character singularly free from foreign influence. Of Tamil words which have found a permanent home in English may be mentioned curry, (*kaṛi*), mulligatawny (*milagu*, pepper, and *taṇṇîr*, cool water), cheroot (*suruṭṭu*), pariah (*paṛeiyan*).

The laws of euphony (avoiding of hiatus, softening of initial consonants, contact of final with initial consonants) are far more complicated in Tamil than in Sanskrit. But, while they were rigidly adhered to in the old poetical language (Sen-Tamil, or "Perfect" Tamil), there is a growing tendency to neglect them in the language of the present day (Koḍun-Tamil). It is true the Tamil rules totally differ from the prevailing Sanskrit; still the probability is in favour of a Sanskrit influence, inasmuch as they appear to follow Sanskrit models. Thus, *iruḷ nîkkinân* becomes *iruṇîkkinân*; *pon pâttiram, poṛpâttiram*; *vîṭṭil kaṇḍên, vuṭṭiṛ kaṇḍên*; *vâlsirumei, vâṭsirumei*; *palan tandân, palanṛândan*. Nouns are divided into high-caste or personal and low-caste or impersonal,—the former comprising words for rational beings, the latter all the rest. Only in high-caste nouns a distinction between masculine and feminine is observed in the singular; both have a common plural, which is indicated by change of a final *n* (feminine *ḷ*) into *r*; but the neuter plural termination *kaḷ* (*gaḷ*) may be super-added in every case. Certain nouns change their base termination before receiving the case affixes, the latter being the same both for singular and plural. They are for the acc. *ei*, instr. *âl*, social *ôḍu* (*oḍu, uḍan*), dat. *ku*, loc. *il* (*iḍattil, in*), abl. *ilirundu* (*ininṛu*), gen. *uḍeiya* (*adu*). There is, besides, a general oblique affix *in*, which is not only frequently used for the genitive, but may be inserted before any of the above affixes, to some of which the emphatic particle *ê* may also be superadded. In the old poetry there is a still greater variety of affixes, while there is an option of dispensing with all. Adjectives, when attributive, precede the noun and are unchangeable; when predicative they follow it and receive verbal affixes. The pronouns of the 1st person are sing. *nân* (*yân*), inflexional base *en*, plural *nâm* (*yâm*), infl. *nam*, including, *nângaḷ*, infl. *engaḷ*, excluding the person addressed; of the 2nd person *nî*, infl. *un* (*nin*, *nun*), plural *nîr* (*nîyir*, *nîvir*), *nîngaḷ*, infl. *um*, *ungaḷ* (*num*). To each of those forms, inclusive also of the reflexive pronouns *tân*, *tâm*, *tângal*, a place is assigned in the scale of honorific pronouns. As in the demonstrative pronouns the forms beginning with *i* indicate nearness, those with *a* distance, and (in the old poetry) those with *u* what is between the two, so the same forms beginning with *e* (or *yâ*, as in *yâr*, *âr*, who?) express the interrogative. The verb consists of three elements—the root (generally reducible to one syllable), the tense characteristic, and the personal affix. There are three original moods, the indicative, imperative, and infinitive (the 2nd singular imperative is generally identical with the root), as well as three original tenses, the present, past, and future. The personal affixes are—sing. (1) *-ên*; (2) *-ây*, honorific *-îr*; (3) masc. *-ân*, fem. *-âḷ*, honor. *-âr*, neuter *-adu*; plural (1) *-ôm* (*-âm*, *-êm*); (2) *-îrkaḷ*; (3) masc. fem. *-ârkaḷ*, neut. *-ana*. These affixes serve for all verbs and for each of the three tenses, except that, in the future, *-adu* and *-ana* are replaced by *-um* (*kkum*). It is only in the formation of the tenses that verbs differ, intransitive verbs generally indicating the present by *-kiṟ-* (*-kinṟ-*), the past by *-d-*, *-nd-*, or *-in-*, and the future by *-v-* (*-b-*), and transitive verbs by the corresponding infixes, *-kkiṟ-* (*-kkinṟ-*), *-tt-* (*-nd-*), and *-pp-*; but there are numerous exceptions and seemingly anomalous formations. Other tenses and moods are expressed with the aid of special affixes or auxiliary verbs. Causal verbs are formed by various infixes (*-ppi-*, *-vi-*, *-ttu-*), and the passive by the auxiliary *paḍu*, to fall, or by *uṇ*, to eat, with a noun. The following four peculiarities are characteristic of Tamil:—first, the tenseless negative form of the verb, expressed by the infix *a*, which is elided before dissimilar vowels; second, the predicative employment of two negative particles *illei* and *alla*, the one denying the existence or presence, the other denying the quality or essence; third, the use of two sets of participles,—one, called adjective or relative participle, which supplies the place of a relative clause, the language possessing no relative pronouns, and an ordinary adverbial participle or gerund; and, fourth, the practice of giving adjectives a verbal form by means of personal affixes, which form may again be treated as a noun by attaching to it the declensional terminations, thus: *periya*, great; *periyôm*, we are great; *periyômukku*, to us who are great. The old poetry abounds in verbal forms now obsolete. Adjectives, adverbs and abstract nouns are derived from verbs by certain affixes. All post-positions were originally either nouns or verbal forms. *Oratio indirecta* is unknown in Tamil, as it is in all the other Indian languages, the gerund *enṟu* being used, like *iti* in Sanskrit, to indicate quotation. The structure of sentences is an exact counterpart of the structure of words, inasmuch as that which qualifies always precedes that which is qualified. Thus the attributive precedes the substantive, the substantive precedes the preposition, the adverb precedes the verb, the secondary clause the primary one, and the verb closes the sentence. The sentence, "Having called the woman who had killed the child, he asked why she had committed such infanticide," runs in Tamil as follows:—

Kuḷandeiyei kkonṟupottavaḷei aḷeippittu nî ên ippaḍi
The child her who had killed having caused to be called, "Thou why thus
ppaṭṭa sisu-v-atti seydây ênṟu kettân.
made child-murder didst?" having said he asked.

Much as the similarity of the structure of the Tamil and its sister languages to that of the Ugro-Tartar class may have proved suggestive of the assumption of a family affinity between the two classes, such an affinity, if it exist, must be held to be at least very distant, inasmuch as the assumption receives but the faintest shade of support from an intercomparison of the radical and least variable portion of the respective languages.

Literature.—The early existence, in southern India, of peoples, localities, animals and products the names of which, as mentioned in the Old Testament and in Greek and Roman writers, have been identified with corresponding Dravidian terms, goes far to prove the high antiquity, if not of the Tamil language, at least of some form of Dravidian speech (Caldwell, *loc. cit.*, Introd., pp. 81–106; *Madras District Manual*, i., Introd., pp. 134 seq.). But practically the earliest extant records of the Tamil language do not ascend higher than the middle of the 8th century of the Christian era, the grant in possession of the Israelites at Cochin being assigned by the late Dr Burnell to about 750 A.D., a period when Malayâḷam did not exist yet as a separate language. There is every probability that about the same time a number of Tamil works sprung up, which are mentioned by a writer in the 11th century as representing the old literature (Burnell, *loc. cit.*, p. 127, note). The earlier of these may have been Saiva books; the more prominent of the others were decidedly Jain. Though traces of a north Indian influence are palpable in all of them that have come down to us (see, *e.g.*, F. W. Ellis's notes to the *Kuṟaḷ*), we can at the same time perceive, as we must certainly appreciate, the desire of the authors to oppose the influence of Brahmanical writings, and create a literature that should rival Sanskrit books and appeal to the sentiments of the people at large. But the refinement of the poetical language, as adapted to the genius of Tamil, has been carried to greater excess than in Sanskrit; and this artificial character of the so-called Sen-Tamil is evident from a comparison with the old inscriptions, which are a reflex of the language of the people, and clearly show that Tamil has not undergone any essential change (Burnell, *loc*, *cit.*, p. 142).

The rules of Sen-Tamil appear to have been fixed at a very early date. The *Tolkâppiyam*, the oldest extant Tamil grammar, is assigned by Dr Burnell (*On the Aindra School of Sanskrit Grammarians*, pp. 8, 55) to the 8th century (best edition by C. Y. Tâmodaram Pillei, Madras, 1885). The *Vîrasôḷiyam*, another grammar, is of the 11th century. Both have been superseded by the *Nannûl*, of the 15th century, which has exercised the skill of numerous commentators, and continues to be the leading native authority (English editions in Pope's *Third Tamil Grammar*, and an abridgment by Lazarus, 1884). The period of the prevalence of the Jains in the Pâṇḍya kingdom, from the 9th or 10th to the 13th century, is justly termed the Augustan age of Tamil literature. To its earlier days is assigned the *Nâlaḍiyâr*, an ethical poem on the three objects of existence, which is supposed to have preceded the *Kuṟaḷ* of Tiruvaḷḷuvan, the finest poetical production in the whole range of Tamil composition. Tradition, in keeping with the spirit of antagonism to Brahmanical influence, says that its author was a pariah. It consists of 1330 stanzas on virtue, wealth and pleasure. It has often been edited, translated and commented upon; see the introduction to the excellent edition published by the Rev. Dr Pope, in which also a comprehensive account of the peculiarities of Sen-Tamil will be found. To the Avvei, or Matron, a reputed sister of Tiruvaḷḷuvan, but probably of a later date, two shorter moral poems, called *Attisûḍi* and *Konṟeivêyndan*, are ascribed, which are still read in all Tamil schools. *Chintâmaṇi*, an epic of upwards of 3000 stanzas, which celebrates the exploits of a king Jîvakan, also belongs to that early Jain period, and so does the *Divâkaram*, the oldest dictionary of classical Tamil. The former is one of the finest poems in the language; but no more than the first and part of the third of its thirteen books have been edited and translated. Kamban's *Râmâyaṇam* (about 1100 A.D.) is the only other Tamil epic which comes up to the *Chintâmaṇi* in poetical beauty. The most brilliant of the poetical productions which appeared in the period of the Saiva revival (13th and 14th centuries) are two collections of hymns addressed to Siva, the one called *Tiruvâsakam*, by Mâṇikka-Vâsakan, and a later and larger one called *Têvâram*, by Sambandhan and two other devotees, Sundaran and Appan. Both these collections have been printed, the former in one, the latter in five volumes. They are rivalled both in religious fervour and in poetical merit by a contemporaneous collection of Vaishṇava hymns, the *Nâlâyira-prabandham* (also printed at Madras). The third section of it, called *Tiruvâymoḷi*, or "Words of the Sacred Mouth," has been published in Telugu characters, with ample commentaries, in ten quartos (Madras, 1875–76). After a period of literary torpor, which lasted nearly two centuries, King Vallabha Deva, better known by his assumed name Ativîrarâma Pâṇḍyan (second half of the 16th century), endeavoured to revive the love of poetry by compositions of his own, the most celebrated of which are the *Neiḍadam*, a somewhat extravagant imitation of Srî Harsha's Sanskrit *Naishadham*, and the *Veṟṟivêrkei*, a collection of sententious maxims. Though he had numerous followers, who made this revival the most prolific in the whole history of Tamil literature, none of the compositions of any kind, mainly translations and bombastic imitations of Sanskrit models, have attained to any fame. An exceptional place, however, is occupied by certain Tamil sectarians called *śittar* (*i.e. siddhas* or sages), whose mystical poems, especially those contained in the *Sivavâkyam*, are said to be of singular beauty. Two poems of high merit, composed at the end of the 17th century, also deserve favourable notice—the *Nîtineriviḷakkam*, an ethical treatise by Kumâragurupara Desikan, and the *Prabhulingalîlei*, a translation from the Kanarese of a famous text-book of the Vîra-Saiva sect. See the analysis in W. Taylor's *Catalogue*, vol. ii. pp. 837–47.

The modern period, which may be said to date from the beginning of the last century, is ushered in by two great poets, one native and the other foreign. Tâyumânavan, a philosopher of the pantheistic school, composed 1453 stanzas (*pâdal*) which have a high reputation for sublimity both of sentiment and style; and the Italian Jesuit Joseph Beschi (d. 1742), under the name Vîramâmuni, elaborated, on the model of the *Chintâmaṇi*, a religious epic *Têmbâvaṇi*, which.

though marred by blemishes of taste, is classed by native critics among the best productions of their literature. It treats of the history of St Joseph, and has been printed at Pondicherry in three volumes, with a full analysis. English influence has here, as in Bengal and elsewhere in India, greatly tended to create a healthier tone in literature both as to style and sentiment. As one of the best Tamil translations of English books in respect of diction and idiom may be mentioned the *Bâlavyâpârikal*, or "Little Merchants," published by the Vernacular Text Society, Madras. P. Percival's collection of *Tamil Proverbs* (3rd ed., 1875) should also be mentioned. The copper-plate grants, commonly called *ŝâsanams*, and stone inscriptions in Tamil, many of which have been copied and translated (*Archaeological Survey of Southern India*, vol. iv.; R. Sewell, *Lists of the Antiquarian Remains in the Presidency of Madras*, vols. i., ii.), are the only authentic historical records. (See also Sir Walter Elliot's contribution to the *International Numismata Orientalia*, vol. iii. pt. 2.) As early as the time of the Chinese traveller Hsüan Tsang, books were written in southern India on talipot leaves, and Albiruni mentions this custom as quite prevalent in his time (1031). It has not died out even at the present day, though paper imported from Portugal has, during the last three centuries, occasionally been used. Madras is now the largest depository of Tamil palm-leaf MSS., which have been described in Wilson's *Catalogue of the Mackenzie Collection* (Calcutta, 1828, 2 vols.), W. Taylor's *Catalogue* (Madras, 1857, 3 vols.), and Condaswamy Iyer's *Catalogue* (vol. i., Madras, 1861). The art of printing, however, which was introduced in southern India at an early date, while it has tended to the preservation of many valuable productions of the ancient literature, has also been the means of perpetuating and circulating a deal of literary rubbish and lasciviousness which would much better have remained in the obscurity of manuscript. Dr Burnell has a note in his *Elements of South Indian Paleography* (2nd ed., p. 44), from which it appears that in 1578 Tamil types were cut by Father João de Faria, and that a hundred years later a Tamil and Portuguese dictionary was published at Ambalakkâḍu. At present the number of Tamil books (inclusive of newspapers) printed annually far exceeds that of all the other Dravidian vernaculars put together. The earliest Tamil version of the New Testament was commenced by the Dutch in Ceylon in 1688; Fabricius's translation appeared at Tranquebar in 1715. Since then many new translations of the whole Bible have been printed, and some of them have passed through several editions. The German missionary B. Ziegenbalg was the first to make the study of Tamil possible in Europe by the publication of his *Grammatica Damulica*, which appeared at Halle in 1716. Some time later the Jesuit father Beschi devoted much time and labour to the composition of grammars both of the vulgar and the poetical dialect. The former is treated in his *Grammatica Latino-Tamulica*, which was written in 1728, but was not printed till eleven years later (Tranquebar, 1739). It was twice reprinted, and two English translations have been published (1831, 1848). His *Sen-Tamil Grammar*, accessible since 1822 in an English translation by Dr Babington, was printed from his own MS. (*Clavis humaniorum literarum sublimioris Tamulici idiomatis*) at Tranquebar in 1876. This work is especially valuable, as the greater portion of it consists of a learned and exhaustive treatise on Tamil prosody and rhetoric. (See, on his other works, Graul's *Reise*, vol. iv. p. 327.) There are also grammars by Anderson, Rhenius, Graul (in vol. ii. of his *Bibliotheca Tamulica*, Leipzig, 1855), Lazarus (Madras, 1878), Pope (4th edition in three parts, London, 1883–85), and *Grammaire Française-Tamoule*, by the Abbé Dupuis (Pondicherry, 1863). The last two are by far the best. The India Office library possesses a MS. dictionary and grammar "par le Rév. Père Dominique" (Pondicherry, 1843), and a copy of a MS. Tamil-Latin dictionary by the celebrated missionary Schwarz, in which 9000 words are explained. About the like number of words are given in the dictionary of Fabricius and Breithaupt (Madras, 1779 and 1809). Rottler's dictionary, the publication of which was commenced in 1834, is a far more ambitious work. But neither it nor Winslow's (1862) come up to the standard of Tamil scholarship; the *Dictionnaire Tamoul-Français*, which appeared at Pondicherry in 2 vols. (1855–62), is superior to both, just as the *Dictionarium Latino-Gallico-Tamulicum* (*ibid.*, 1846) excels the various English-Tamil dictionaries which have been published at Madras.

Murdoch, *Classified Catalogue of Tamil Printed Books*, Madras, 1865; C. E. Gover, *Folk-Songs of Southern India*, Madras, 1871; Bishop Caldwell's *Comparative Grammar of the Dravidian Languages*, 2nd ed., London, 1875; Graul's *Reise nach Ostindien*, vols. iv. and v.; the quarterly *Lists of Books* registered in the Madras Presidency; [Dr. Maclean's] *Manual of the Administration of the Madras Presidency*, vols. i. and ii., Madras, 1885, folio; F. Müller, *Grundriss der Sprachwissenschaft*, Vienna, 1884, iii. i. 162–246; G. U. Pope, *First Lessons in Tamil*, 7th ed., Oxford, 1904, and *The Nāladiyār*, Oxford, 1893; and J. Vinson, *Manuel de la Langue Tamoule*, Paris, 1903. (R. R.)

TAMLUK, an ancient town of British India, in the Midnapore district of Bengal, on the river Rupnarayan. Pop. (1901) 8805. Under the name of Tamralipta was the capital of the Peacock dynasty, and a seaport at which the Chinese Buddhist pilgrims embarked. It is now 60 m. from the sea, and the ruins of the old city lie deep beneath river silt. It contains the palace of a local raja, and some temples of peculiar construction.

TAMMANY HALL, a political organization in New York City, U.S.A., claiming to be the regular representative of the Democratic party in that city. It takes its name from a sachem or chief of the Delaware Indians, Tamanend or Tammany, the name itself meaning "the Affable." Before the War of Independence there were Whig societies called "Sons of St Tammany" and "Sons of Liberty," with rituals in which Indian words were used to suggest the American character of the lodges. On the 12th of May 1789 William Mooney (d. 1832), an upholsterer, of Irish birth, who had probably been a member of an earlier Tammany society, founded in New York City the "Society of St Tammany" or "Columbian Order" as a patriotic, benevolent and non-political organization, with the intent to counteract the influence of what was believed to be the aristocratic Order of the Cincinnati. A few short-lived societies of a similar kind were founded in other states. In 1805 the New York Society was incorporated as a benevolent society, in 1811 it built its first wigwam, or hall, in Frankfort Street near the City Hall, and in 1867 it moved to its present hall in Fourteenth Street. The society was a secret organization, divided into tribes, with sachems (the most important being the Grand Sachem) as the chief officials, a sagamore, or master of ceremonies, and a winskinskie, or door-keeper, and with a ritual of supposedly Indian character. This "Tammany Society" is not itself the well-known political organization, but rents its hall to the Tammany Hall General Committee, the "Tammany Hall" of political notoriety; the leading members, however, of the "Society" and of the "Hall" are identical, and the "Society" controls the meeting-place of the "Hall," so that the difference between the two is little more than nominal. Almost from the beginning Tammany has been actively engaged in politics, being part of, and during the greater period of its existence actually representing in New York City, the Democratic party, though always subordinating the interests of the party as a whole to its own selfish interests. It has had local rivals at different times, but these, though successful for a while, have not lived long; on the other hand, the Hall has not generally been regarded with favour by the Democratic party throughout the country at large.

Soon after its founding, Tammany came under the influence of Aaron Burr. In 1800 it worked for the election of Jefferson as President. It bitterly opposed De Witt Clinton for many years and was hostile to his large Irish constituency; but, after it secured in 1822 the constitutional amendments providing for manhood suffrage and for the abolition of imprisonment of debtors, and especially after 1827 when Tammany first tried to reduce the five-year period of residence necessary for naturalization, the foreign-born element gradually came into control of the "Society" and of the "Hall." About 1842 Irish "gangs," which used physical violence at election time, became a source of Tammany strength. It reached its height of power about 1870, under the leadership of William Marcy Tweed (1823–78), who used his popularity as a volunteer fireman to advance himself in Tammany and who was the first "boss" of the organization, which had formerly been controlled by committees. In the mayoralty and the other administrative offices and in the common council of the city, in the chief executive office of the state, in the state legislature, and even in some of the judges' seats, Tweed had placed (or had secured the election of) accomplices or tools, or else controlled votes by purchase. In April 1870 Tweed secured the passage of a city charter which put the control of the city into the hands of the mayor, the comptroller, and the commissioners of parks and public works. A system of official plunder then began that has had few parrallels in modern times. How much was actually stolen can never be known; but the bonded debt of the city, which was $36,000,000 at the beginning of 1869, was $97,000,000 in September 1871, an increase of $61,000,000 in two years and eight months; and within the same period a floating debt of $20,000,000 was incurred, making a total of $81,000,000. For this vast sum the city had little to show. The method of plunder was the presentation of excessive bills for work done, especially in connexion with the new court-house then being erected. The bills were ostensibly paid in full, but in reality only in part, the rest being retained by Tweed, and divided amongst his followers in proportion to their importance. The total cost of the court-house to the city was about $13,000,000—many times the actual cost of construction. The amount paid in these two years for the city printing and stationery was nearly $3,000,000. The end came through a petty quarrel over the division of the spoils. One of the plunderers, dissatisfied with the office he had received, gave to the *New York Times* a copy of certain swollen accounts which showed conclusively the stealing that had been going on. When Tweed was interviewed about the frauds his only reply was, "What are you going to do about it?" The better classes, however, were now thoroughly aroused, and with Samuel J. Tilden, afterwards governor of the state, at their head, and with the assistance of the *Times* and of *Harper's Weekly*, in the latter of which the powerful cartoons of Thomas Nast appeared, completely overthrew the ring and rescued the city. Tweed was tried and convicted, but was afterwards released on a technicality of law; he was re-arrested, but managed to escape and fled to Spain; he was identified and was brought back to gaol, where he died. The rest of the gang fared little better. Within a few years and under a new leader, John Kelly, Tammany was again in control of the city. Kelly was succeeded by Richard Croker, whose reign as "boss" continued until 1901. Since 1881 Tammany has been in virtual control of the city government about one-half the time, a Tammany and a reform mayor often alternating. There were elaborate investigations of Tammany's control of the city by committees of the legislature in 1890, 1894, and 1899. The most conspicuous overthrows of Tammany since the days of Tweed were in 1894, in 1901, when practically the whole reform ticket from mayor to alderman was elected, and in 1909, when the mayor (not a member of Tammany) was the only Tammany nominee on the general ticket elected. The grosser forms of corruption that prevailed under Tweed did not as a rule prevail in later years. Instead, the money raised by and for the Hall and its leaders has come from the blackmailing of corporations, which find it easier to buy peace than to fight for their rights; from corporations which desire concessions from the city, or which do not wish to be interfered with in encroachments on public rights; from liquor-dealers, whose licences are more or less at the mercy of an unscrupulous party in power; from other dealers, especially in the poorer parts of the city, whose business can be hampered by the police; from office-holders and candidates for office; and, lastly, indirectly through corrupt police officials, from the criminal classes and gambling establishments in return for non-intervention on the part of the police. The power of Tammany Hall is the natural result of the well-regulated machine which it has built up throughout the city, directed by an omnipotent "boss." Each of the "assembly districts" into which the city is divided sends a certain number of representatives to the General Committee of Tammany Hall. Each district also has a "boss" or leader and a committee, and these leaders form the Executive Committee of the Hall. There is also a "captain" for each of the voting precincts, over 1000 in number, into which the city is divided. The patronage of the city filters down from the real "boss" of the Hall to the local precinct leader, the latter often having one or more small municipal offices at his disposal; he also handles the election money spent in his precinct. The party headquarters in the different assembly districts are largely in the nature of social clubs, and it is in considerable degree through social means that the control of the Hall over the poorer classes is maintained. The headquarters are generally over or near a saloon, and the saloon-keepers throughout Manhattan belong as a rule to the Hall—in fact, are its most effective allies or members. It should be remembered too that the Hall is not subject to divided counsels, but is ruled by one man, a "boss" who has risen to his position by sheer force of ability, and in whose hands rest the finances of the Hall, for which he is accountable to no one. When the "Greater New York" was incorporated the power of Tammany seemed likely to grow less because it was confined to the old city (Boroughs of Manhattan and the Bronx), and the Democratic organizations in the other boroughs were hostile to it. The power of the organization in the state and in the nation is due to its frequent combination with the Republican organization, which controls the state almost as completely as Tammany does the city.

See Gustavus Myers, *The History of Tammany Hall* (New York, 1901). (F. H. H.)

TAMMERFORS (Finnish *Tampere*), the chief industrial city of Finland, capital of the province of Tavastehus, on the rapids connecting Lakes Näsi-järvi and Pyhä-järvi, 125 m. by rail N.W. of Helsingfors. Pop. (1904) 40,261. Tammerfors is an important centre for the manufacture of cotton, linen, and woollen goods, leather and paper. The town owes its existence as a manufacturing centre to the tsar Alexander I.

TAMPA, a city and the county seat of Hillsboro county, Florida, U.S.A., in the western part of the state, at the head of Hillsborough Bay (the E. branch of Tampa Bay), at the mouth of the Hillsborough river. Pop. (1880) 720; (1890) 5532; (1900) 15,839, of whom 5085 were foreign-born and 4382 were negroes; (1910, U.S. census) 37,782. It is served by the Tampa Northern, the Atlantic Coast Line and the Seaboard Air Line railways, and by lines of steamers to the West Indies and to the Gulf and Atlantic ports of the United States. The larger vessels enter at Port Tampa (pop. in 1905, 1049), 9 m. from the city, on the W. side of the peninsula separating Hillsborough Bay from Old Tampa Bay, the W. branch of Tampa Bay. In order to reach water sufficiently deep for the steamers, the railway tracks have been carried by earth filling about seven-eighths of a mile into the bay. The United States government has greatly improved the harbour, and in 1899 adopted a project (modified in 1905) for constructing a channel 26 ft. deep and 300 ft. wide (500 ft. across the bar) from Port Tampa to the Gulf of Mexico; in July 1909 80 per cent. of this work had been completed. In 1905–1908 the channel of Hillsborough Bay was made 20 ft. deep at mean low water and 150 ft. wide from the lower bay to the mouth of Hillsborough river, with a turning basin at the inner end 450 ft. wide and 1050 ft. long. Tampa Bay has permanent sea-coast defences. Tampa is the principal gateway for trade and travel between the United States and the West Indies. Owing to its delightful climate and its attractive situation it has become a favourite health resort. Many visitors are attracted by the fishing (especially for tarpon) and shooting in the vicinity, water-fowl being plentiful in the Bay, and deer, quail and wild turkeys being found in the vicinity inland. There are large prehistoric shell-mounds at Indian Hill, about 20 m. S.E. Tampa is an important shipping point for naval stores and phosphate rock, for vegetables, citrus fruit and pineapples, raised in the vicinity, and for lumber, cattle and fuller's earth. The Florida Citrus Exchange has its headquarters here. After the Spanish-American War (1898) a large trade with the West Indies developed. Cattle and pine lumber are sent to Cuba, and Havana tobacco and fine grades of Cuban timber are imported. There is a large trade with Honduras also. The imports increased from $755,316 in 1897 and $490,093 in 1898 (an extremely unfavourable year owing to the Spanish-American War) to $4,179,464 in 1909; the exports from $820,792 in 1897 and $521,792 in 1898 to $1,344,786 in 1899 and $4,492,498 in 1909; a part of the custom-house clearings of Key West are actually shipped from Tampa. In 1905 the value of the factory product was $11,264,123, an increase of 59 per cent. since 1900. The principal product is cigars; most of the tobacco used is imported from Cuba, and the manufacturing is done chiefly by Cubans who live in a district known as Ybor City. It is said that more clear Havana cigars are manufactured in Tampa than in Havana. Other manufactures are boilers, foundry products, lumber and fertilizers; and there are two shipyards.

Tampa Bay was the landing-place of the expeditions of the Spanish explorers, Pamfilo de Narvaez and Hernando de Soto. (See FLORIDA.) In January 1824 the United States government established here a fort, Fort Brooke, which was an important base of supplies during the second Seminole War, and around it a settlement gradually developed. The fort was abandoned in 1860, and its site is now a public park. During the early part of the Civil War a small Confederate force was in possession, but in November 1862 it was driven out by United States gunboats. Tampa grew rapidly after the completion of the first railway thither in 1884, and in 1886 it was chartered as a city and became a port of entry. During the Spanish-American War United States troops were encamped in De Soto Park in Tampa, and Port Tampa was the point of embarkation for the United States army that invaded Cuba.

TAMPICO, a city and port of Mexico, in the state of Tamaulipas, on the N. bank of the Panuco river, about 6 m. from the Gulf of Mexico. Pop. (1906) 17,569, including the neighbouring settlements connected with the port works. The climate is hot, humid and unhealthy, and the city has suffered frequently from epidemics of yellow fever. A modern sewer system and waterworks, constructed in 1903–1906, have improved its sanitary condition and will in time reduce its heavy death-rate—about 78 per 1000 in 1903, when an epidemic of yellow fever caused 327 deaths, and the births numbered 512 against 1335 deaths. The eastern and poorer part of the town stands on low ground only 2 or 3 ft. above the river, and is subject to inundations. The western part rises about 150 ft., consists largely of private residences, and is provided with water and good drainage. The business section is well built, largely of stone and brick, and its streets are well paved and provided with gas and electric light. The neighbourhood is swampy and malarial. Tampico has two important railway connexions: the Monterrey and Gulf line running N.N.W. to Ciudad, Victoria and Monterrey, and a branch of the Mexican Central running westward to San Luis Potosi. There is also a line of river boats on the Panuco running up to the mouth of the Tamazunchale about 135 m., and another running to Tamiahua on the lagoon of that name by way of the Tuxpam canal, about 77 m. Industries include an electric light and power plant, factories for making ice, clothing, and fruit conserves, saw-mill, oil refinery, and a shipyard for small river boats. The modern port works, which have made Tampico accessible to a larger class of steamers, include two stone jetties at the mouth of the Panuco, which have increased the depth of water on the bar to 23 ft. at low water and 26 ft. at high water; seven wharves on the N. bank of the river to accommodate fourteen steamers at a time; steel sheds with railway tracks, and railway connexions at the wharves. The depth of water at the wharves varies from 18 to 25 ft. The exports include silver bullion (from San Luis Potosi, Aguascalientes, Torreon and Monterrey), ixtle fibre, sugar, hides, live cattle, cotton-seed cake, deer skins, honey, fustic, sarsaparilla, coffee, rubber, broom-root, copper ores and asphalt.

TAMWORTH, a municipality of Inglis county, New South Wales, Australia, on the Peel and Cockburn rivers, 285 m. by rail N. of Sydney. Pop. (1901) 5799. It is an attractive town in a pleasant situation, with fine broad streets lined with shady trees, and was the first town in Australia to be lighted by electricity. Tamworth is the centre of several goldfields, at one of which, Bingera, diamonds are found. It is also the market of a pastoral and agricultural district. Brewing, malting, steam, saw and flour milling, coach building and the manufacture of boots and galvanized iron are its principal industries.

TAMWORTH, a market town and municipal borough of England, in the Lichfield parliamentary division of Staffordshire and the Tamworth division of Warwickshire, on the river Tame, a southern tributary of the Trent. Pop. (1901) 7271. It is 110 m. N.E. from London by the London and North-Western railway, and is also served by the west and north line of the Midland railway (Bristol-Birmingham-Derby). The castle, situated on a height above the Anker near its junction with the Tame, is chiefly of the Jacobean period, but is enclosed by massive ancient walls. Here was a residence of the Mercian kings, and, after being bestowed on the Marmions by William the Conqueror, the castle remained for many years an important fortress. Formerly the town was surrounded by a ditch called the King's Dyke, of which some trace remains. The church of St Editha, originally founded in the 8th century, was rebuilt, after being burned by the Danes, by Edgar, who made it collegiate, but the existing Decorated building, was erected after a fire in 1345. The free grammar school, refounded by Edward IV., was rebuilt in 1677, and again in 1867. The charities include Guy's almshouses, endowed in 1678 by Thomas Guy, founder of Guy's Hospital, London. On the commons or moors burgesses have rights of pasture. Coal, fireclay and blue and red brick clay are dug in the neighbourhood; and there are also market gardens. In the town are a clothing factory, paper-mills, and manufactures of small wares. The town is governed by a mayor, 4 aldermen, and 12 councillors. Area, 285 acres.

Tamworth (*Tamwurda*, *Thamworth*, *Tomworth*) is situated near the Roman Watling Street. It was burned by the Danes and restored in 913 by Aethelflead, lady of the Mercians, who built the fort which was the origin of the later castle. The town was again destroyed by the Danes in 943. There is no description of Tamworth in Domesday, but its burgesses are incidentally mentioned several times. In Anglo-Saxon and Norman times it possessed a mint, and it is called a borough in the Pipe Rolls of Henry II., but it was not then in a flourishing condition. Tamworth was incorporated by Elizabeth in 1560 by letters patent, which state that it is an "ancient mercate town," and suggest that the charters have been lost or burned. The governing charter in 1835 was that of Charles II., incorporating it under the title of the bailiffs and commonalty of the borough of Tamworth in the counties of Stafford and Warwick. Edward III. granted two fairs, still kept up in 1792, to be held respectively on St George's day and the day of the Translation of St Edward; another ancient fair, in honour of St Swithin, or perhaps originally of St Editha, is still held (July 26). Tamworth sent two members to parliament from 1562 to 1885, when its representation was merged in that of the county.

TANA, a river of British East Africa, which gives its name to the Tanaland province of that protectorate. It has a course, following the main windings only, of over 500 m. Its sources are along the watershed close to the eastern wall of the eastern rift-valley, and it enters the Indian Ocean in 2° 40′ S., about 110 m. N. by E. of Mombasa. One series of its numerous headstreams traverses the Kikuyu plateau north of the Athi, while others flow down the southern and eastern slopes of Kenya. The main stream, from about 37° E. 1° S., where it runs close to the upper waters of the Athi, flows in a wide curve N.E., nearly reaching the equator. About 39° E. it turns S., and from this point is not known to receive any tributary of importance. Its course is very tortuous, the current rapid, and the channel much obstructed by snags. Its width varies, as a general rule, between 100 and 200 yds. The banks are usually low, in part forested and inundated at high water, but away from the river the country appears to consist of dry plains covered with mimosa scrub. Adjoining the lower Tana are many backwaters, which seem to show that the course has been subject to great changes. In 2° 20′ S. the river again turns east, but during the last 10 m. it flows south-west, parallel to the coast, entering the sea across a dangerous bar. The Tana has been navigated in a steam-launch for some 300 m. from the mouth. North of the Tana is the Ozi, a small river connected with the Tana by the Belazoni canal.

TANAGER, a word adapted from the quasi-Latin *Tanagra* of Linnaeus, which again is an adaptation, perhaps with a classical allusion, of *Tangara*, used by M. J. Brisson and G. L. L. Buffon, and said by G. de L. Marcgrave (*Hist. Rer. Nat. Brasiliae*, p. 214) to be the Brazilian name of certain birds found in that country. From them it has since been extended to a great many others mostly belonging to the southern portion of the New World, now recognized by ornithologists as forming a distinct family *Tanagridae* of the *Oscines* division of Passerine birds allied to the *Fringillidae* (see FINCH); and distinguished from them chiefly by their feebler conformation and more exposed nostrils. They are confined to the New World, and are specially characteristic of the tropical forests of Central and South America.

The tanagers have been examined systematically by P. L. Sclater, and in the British Museum *Catalogue* (xi. pp. 49–307) he admits the existence of 375 species, which he arranges in 59 genera, forming six subfamilies, *Procniatinae*, *Euphoniinae*, *Tanagrinae*, *Lamprotinae*, *Phoenicophilinae*, and *Pitylinae*. These are of very unequal extent, for, while the first of them consists of but a single species, *Procnias tersa*—the position of which may be for several reasons still open to doubt—the third includes more than 200. Nearly all are birds of small size, the largest barely exceeding a song-thrush. Most of them are remarkable for their gaudy colouring, and this is especially the case in those forming the genus called by Sclater, as by most other authors, *Calliste*, a term inadmissible through preoccupation, to which the name of *Tanagra* of right seems to belong, while that which he names *Tanagra* should probably be known as *Thraupis*. The whole family is almost confined to the Neotropical region, and there are several forms peculiar to the Antilles; but not a tenth of the species reach even southern Mexico, and not a dozen appear in the northern part of that country. Of the genus *Pyranga*, which has the most northern range of all, three if not four species are common summer immigrants to some part or other of the United States, and two of them, *P. rubra* and *P. aestiva*, known as the scarlet tanager and the summer redbird, reach Canada and Bermuda. *P. aestiva* has a western representative, *P. cooperi*, which by some authors is not recognized as a distinct species. The males of all these are clad in glowing red, *P. rubra* having, however, the wings and tail black. The remaining species, *P. ludoviciana*, the males of which are mostly yellow and black, with the head only red, does not appear eastward of the Missouri plains, and has not so northerly a range. Another species, *P. hepatica*, has shown itself within the limits of the United States. In all these the females are plainly attired; but generally among the Tanagers, however bright may be their coloration, both sexes are nearly alike in plumage. Little has been recorded of the habits of the species of Central or South America, but those of the north have been as closely observed as the rather retiring nature of the birds renders possible, and it is known that insects, especially in the larval condition, and berries afford the greater part of their food. They have a pleasing song, and build a shallow nest, in which the eggs, generally three in number and of a greenish-blue marked with brown and purple, are laid. A few species are regularly but sparingly imported into Europe alive, and do well as cage birds.

On the whole the *Tanagridae* may perhaps be considered to hold the same relation to the *Fringillidae* as the *Icteridae* do to the *Sturnidae* and the *Mniotiltidae* to the *Sylviinae* or *Turdinae*, in each case the purely New-World Family being the "feebler" type.

(A. N.)

TANAQUIL, the Etruscan name of the wife of Tarquinius Priscus, or of one of his sons. After her immigration to Rome she is said to have received the name Gaia Caecilia. She was famous for her shrewdness and prophetic gifts, which enabled her to foretell the future greatness of her husband and of Servius Tullius. There was a statue of her as Gaia Caecilia in the temple of Sancus, which possessed magical powers. She was celebrated as a spinner of wool, and was supposed to exercise influence over Roman brides. Tanaquil and Gaia Caecilia are, however, really distinct personalities. The anecdotes told of Gaia Caecilia are aetiological myths intended to explain certain usages at Roman marriages.

See Livy, i. 34, 41; Pliny, *Nat. Hist.*, viii. 74, xxxvi. 70; Schwegler, *Römische Geschichte*, bk. xv. 8.

TANAUAN, a town of the province of Batangas, Luzon, Philippine Islands, about 38 m. S.S.E. of Manila. Pop. (1903) 18,263. Tanauan is situated on a rolling upland plain. It formerly produced much sugar, but its inhabitants are now engaged chiefly in the cultivation of rice, Indian corn and fruit. Oranges and hogs are sent from Tanauan to the Manila market. The language is Tagalog.

TANCRED (d. 1112), nephew of Bohemund and a grandson of Robert Guiscard on the female side, was the son of a certain *Marchisus*, in whom some have seen a marquis, and some an Arab (Makrizi). He took the Cross with Bohemund in 1096, and marched with him to Constantinople. Here he refused to take an oath to Alexius, escaping across the Bosphorus in the disguise of a peasant; but after the capture of Nicaea he consented to follow the example of the other princes, and became the man of Alexius. At Heraclea, in the centre of Asia Minor, he left the main body of the Crusaders, and struck into Cilicia, closely followed by Baldwin of Lorraine. He may have been intending, in this expedition, to prepare a basis for Bohemund's eastern principality; in any case, he made himself master of Tarsus, and when he was evicted from it by the superior forces of Baldwin, he pushed further onwards, and took the towns of Adana and Mamistra. He joined the main army before Antioch, and took a great part in the siege. When, in the spring of 1098, two castles were erected by the crusaders, it was Tancred who undertook the defence of the more exposed castle, which lay by St George's Gate, on the west of the city. In the beginning of 1099 he was serving in the ranks of Raymund's army, whether to observe his movements in the interests of Bohemund, or only (as is more probable) to be in the front of the fighting and the march to Jerusalem. But he soon left the count, like so many of the other pilgrims (see under RAYMUND); and he joined himself to Godfrey of Lorraine in the final march. In June 1099 he helped Baldwin de Burg (his future rival) in the capture of Bethlehem; and he played his part in the siege of Jerusalem, gaining much booty when the city was captured, and falling into a passion because the security he had given to the fugitives on the roof of Solomon's temple was not observed by the crusaders. After the capture of Jerusalem he went to Naplous, and began to found a principality of his own. He took part in the battle of Ascalon in August; and after it he was invested by Godfrey with Tiberias and the principality of Galilee, to the north of Naplous. In 1100 he attempted, without success, to prevent Baldwin of Lorraine (his old enemy in Cilicia) from acquiring the throne of Jerusalem, possibly having ambitions himself, and in any case fearing the foundation of a strong non-Norman power in Palestine. Failing in this attempt, and being urgently summoned from the North to succeed Bohemund (now a prisoner with Danishmend) in the government of Antioch, he surrendered his smaller possessions to Baldwin, on condition that they should be restored if he returned in a year and three months, and finally left the kingdom of Jerusalem. He acted as regent in Antioch from 1100 to 1103, when Bohemund regained his liberty. During these years he succeeded in regaining the Cilician towns for Antioch (1101), and in recapturing Laodicea (1103); he imprisoned Raymund of Toulouse, and only gave him his liberty on stringent conditions; and he caused the restoration of the deposed patriarch of Jerusalem, Dagobert, if only for a brief season, by refusing to aid Baldwin I. on any other terms. When Bohemund was set free, Tancred had to surrender Antioch to him; but he soon found fresh work for his busy hands. In 1104 he joined with Bohemund and Baldwin de Burg (now count of Edessa in succession to Baldwin of Lorraine) in an expedition against Harran, in which they were heavily defeated, and Baldwin was taken prisoner. Tancred, however, profited doubly by the defeat. He took over the government of Edessa in Baldwin's place; and in 1105 Bohemund surrendered to him the government of Antioch, while he himself went to Europe to seek reinforcements. Ruler of the two northern principalities, Tancred carried on vigorous hostilities against his Mahommedan neighbours, especially Ridwan of Aleppo; and in 1106 he succeeded in capturing Apamea. In 1107, while Bohemund was beginning his last expedition against Alexius, he wrested the whole of Cilicia from the Greeks; and he steadfastly refused, after Bohemund's humiliating treaty at Durazzo in 1108, to agree to any of its stipulations with regard to Antioch and Cilicia. To the hostility of the Mahommedans and the Greeks, Tancred also added that of his own fellow Latins. When Baldwin de Burg regained his liberty in 1108, it was only with difficulty that he was induced to restore Edessa to him, and the two continued unfriendly for some time; while in 1109 he also interfered in the civil war in Tripoli between the nephew and the eldest son of Raymund of Toulouse. But it was against the emirs of Northern Syria that his arms were chiefly directed;

and he became the hammer of the Turks, restlessly attacking the emirs on every side, but especially in Aleppo, and exacting tribute from them all. He died in 1112, leaving the government to his brother-in-law, Roger de Principatu, until such time as Bohemund II. should come to his inheritance.

Bibliography.—Tancred's *Gesta* were recorded by Ralph of Caen, who drew his information from Tancred's own conversation and reminiscences. Kugler has written a work on *Bohemund und Tancred* (Tübingen, 1862); and Tancred's career is also described by Rey, in the *Revue de l'Orient Latin*, iv. 334-340. (E. Br.)

TANCRED (d. 1194), King of Sicily, an illegitimate son of Roger, the eldest son of King Roger II., was crowned in January 1190 in succession to William II. (*q.v.*). He was supported by the chancellor Matthew d'Ajello and the official class, while the rival claims of Roger II.'s daughter Constance and her husband, Henry VI., king of the Romans and emperor, were supported by most of the nobles. Tancred was a good soldier, though his tiny stature earns from Peter of Eboli the nickname "Tancredulus." But he was ill-supported in his task of maintaining the Norman kingdom, faced with general apathy, and threatened by a baronial revolt, and, in addition, Richard Coeur-de-Lion, at Messina, 1190, threatened him with war. Henry, skilfully winning over Pisa, Genoa and the Roman Commune, isolated Tancred and intimidated Celestine III., who, on the 14th of April 1191, crowned him emperor at Rome. He, however, failed to capture Naples in August and retired north, leaving garrisons along the frontiers of the Regno. Tancred now sought to win over the towns by extensive grants of privileges, and at Gravina (June 1192) was recognized by the pope, whose ineffectual support he gained by surrendering the royal legateship over Sicily. In 1192 and 1193 he commanded personally and with success against the Apulian barons, but his death at Palermo (20th of February 1194) a few days after that of Roger, his son and joint-king, made Henry's path clear. His wife Sibilla indeed maintained a regency for her second son William III., but on Henry's final descent, Naples surrendered almost without a blow in May 1194, and the rest of the Regno followed. Sibilla and the loyal Margarito prepared to defend Palermo, but the citizens admitted the emperor on the 20th of November 1194. Tancred's family fell into Henry's hands, and William III. seems to have died in Germany in 1198.

TANDY, JAMES NAPPER (1740-1803), Irish rebel, son of a Dublin ironmonger, was born in Dublin in 1740. He started life as a small tradesman; but turning to politics, he became a member of the corporation of Dublin, and made himself popular by his denunciation of municipal corruption and by his proposal of a boycott of English goods in Ireland, in retaliation for the restrictions imposed by the government on Irish commerce. In April 1780 Tandy was expelled from the Dublin volunteers (see Flood, Henry) for proposing the expulsion of the duke of Leinster, whose moderation had offended the extremists. He was one of the most conspicuous of the small revolutionary party, chiefly of the shopkeeper class, who formed a permanent committee in June 1784 to agitate for reform, and called a convention of delegates from all parts of Ireland, which met in October 1784. Tandy persuaded the corporation of Dublin to condemn by resolution Pitt's amended commercial resolutions in 1785. He became a member of the Whig club founded by Grattan; and he actively co-operated with Theobald Wolfe Tone in founding the Society of the United Irishmen in 1791, of which he became the first secretary. The violence of his opinions, strongly influenced by French revolutionary ideas, now brought Tandy prominently under the notice of the government. In February 1792 an allusion in debate by Toler (afterwards earl of Norbury), the attorney-general, to Tandy's personal ugliness, provoked him into sending a challenge; this was treated by the House of Commons as a breach of privilege, and a Speaker's warrant was issued for his arrest, which however he managed to elude till its validity expired on the prorogation of parliament. Tandy then took proceedings against the lord lieutenant for issuing a proclamation for his arrest; and although the action failed, it increased Tandy's popularity, and his expenses were paid by the Society of the United Irishmen. Sympathy with the French Revolution was at this time rapidly spreading in Ireland. A meeting of some 6000 persons in Belfast voted a congratulatory address to the French nation in July 1791. In the following year Napper Tandy took a leading part in organizing a new military association in Ireland modelled after the French National Guards; they professed republican principles, and on their uniform the cap of liberty instead of the crown surmounted the Irish harp. Tandy also, with the purpose of bringing about a fusion between the Defenders and the United Irishmen, took the oath of the Defenders, a Roman Catholic society whose agrarian and political violence had been increasing for several years; but being threatened with prosecution for this step, and also for libel, he fled to America, where he remained till 1798. In February 1798 he went to Paris, where at this time a number of Irish refugees, the most prominent of whom was Wolfe Tone, were assembled, planning rebellion in Ireland to be supported by a French invasion, and quarrelling among themselves. None of these was more quarrelsome than Napper Tandy, who was exceedingly conceited, and habitually drunken; his vanity was wounded to find himself of less account than Tone in the councils of the conspirators.

Wolfe Tone, who a few months before had patronizingly described him to Talleyrand as "a respectable old man whose patriotism has been known for thirty years," was now disgusted by the lying braggadocio with which Tandy persuaded the French authorities that he was a personage of great wealth and influence in Ireland, at whose appearance 30,000 men would rise in arms. Tandy was not, however, lacking in courage. He accepted the charge of a corvette, the "Anacreon," placed at his disposal by the French government, in which, accompanied by a few leading United Irishmen, and supplied with a small force of men and a considerable quantity of arms and ammunition for distribution in Ireland, he sailed from Dunkirk and arrived at the isle of Aran, off the coast of Donegal, on the 16th of September 1798. The populace showed no disposition to welcome the invaders. Napper Tandy, who was drunk during most of the expedition, took possession of the village of Rutland, where he hoisted an Irish flag and issued a bombastic proclamation; but learning the complete failure of Humbert's expedition, and that Connaught instead of being in open rebellion was perfectly quiet, the futility of the enterprise was apparent to the French if not to Tandy himself; and the latter having been carried on board the "Anacreon" in a state of intoxication, the vessel sailed round the north of Scotland to avoid the English fleet, and reached Bergen in safety, whence Tandy made his way to Hamburg with three or four companions. In compliance with a peremptory demand from the English government, and in spite of a counter-threat from the French Directory, the refugees were surrendered. Tandy remained in prison till April 1801, when he was tried, pleaded guilty, and was sentenced to death; he was, however, reprieved and allowed to go to France. This leniency may have been partly due to doubts as to the legality of the demand for his surrender by the Hamburg authorities; but the government was probably more influenced by Cornwallis's opinion that Tandy was "a fellow of so very contemptible a character that no person in this country (Ireland) seems to care the smallest degree about him." Moreover, Bonaparte vigorously intervened on his behalf, and is even said to have made Tandy's release a condition of signing the treaty of Amiens. Notwithstanding his vices and his lack of all solid capacity, there is no reason to suppose that Napper Tandy was dishonest or insincere; and the manner in which his name was introduced in the well-known ballad, "The Wearing of the Green," proves that he succeeded in impressing the popular imagination of the rebel party in Ireland. In France, where his release was regarded as a French diplomatic victory, he was received, in March 1802, as a person of distinction; and when he died on the 24th of August 1803 his funeral was attended by the military and an immense number of the civil population.

TANEGA-SHIMA, an island lying to the south of Kiushiu, Japan, in 30° 50′ N. and 131° E., 36½ m. long and 7¼ m. broad at its widest part. It is a long low stretch of land, carefully cultivated, and celebrated as the place where Mendez Pinto landed when he found his way to Japan in 1543. Until modern times firearms were colloquially known in Japan as "Tanega-shima," in allusion to the fact that they were introduced by Pinto.

TANEY, ROGER BROOKE (1777–1864), American jurist, was born in Calvert county, Maryland, on the 17th of March 1777, of Roman Catholic parentage. He graduated from Dickinson College, Carlisle, Pennsylvania, in 1795, began the study of law at Annapolis in 1796, and was admitted to the bar in 1799. In 1806 he married Anne Phebe Key, sister of Francis Scott Key. He entered politics as a Federalist, and was a member of the Maryland House of Delegates in 1799–80. His faith in Federalism was weakened by the party's opposition to the War of 1812, and he gradually became associated with the Jacksonian wing of the Republican party. He served in the state Senate in 1816–21, was attorney-general of Maryland in 1827–31; and in July 1831 entered President Jackson's cabinet as attorney-general of the United States. He was the President's chief adviser in the attack on the United States Bank, and was transferred to the treasury department in September 1833 for the special purpose of removing the government deposits. This conduct brought him into conflict with the Senate, which passed a vote of censure, and (in June 1834) refused to confirm his appointment as secretary of the treasury. He returned to his law practice in Baltimore, but on the 28th of December 1835 was nominated Chief-Justice of the United States Supreme Court to succeed John Marshall. After strong opposition the nomination was confirmed, on the 15th of March 1836, by the Senate. Under the guidance of Judges John Jay, Marshall, and Joseph Story, the judiciary from 1790 to 1835 had followed the Federalist loose construction methods of interpreting the constitution. The personnel of the supreme bench was almost entirely changed during President Jackson's administration (1829–37). Five of the seven judges in 1837 were his appointees, and the majority of them were Southerners who had been educated under Democratic influences at a time when the slavery controversy was forcing the party to return to its original strict construction views. In consequence, although the high judicial character of the men appointed and the lawyers' regard for precedent served to keep the court in the path marked out by Marshall and Story, the state sovereignty influence was occasionally manifest, as, for example, in the opinion (written by Taney) in the *Dred Scott* case (1857, 19 Howard, 393) that Congress had no power to abolish slavery in territory acquired after the formation of the national government. During the Civil War, Judge Taney struggled unsuccessfully to protect individual liberty from the encroachments of the military authorities. In the case of *ex parte John Merryman* (1861, Campbell's Reports, 646), he protested against the assumption of power by the President to suspend the privileges of the writ of *habeas corpus* or to confer that power upon a military officer without the authorization of Congress. The delivering of this opinion, on circuit, in Baltimore, in May 1861, was one of the judge's last public acts. He died on the 12th of October 1864.

An authoritative biography is Samuel Tyler's *Memoir of Roger Brooke Taney* (Baltimore, 1872).

TANGA ("the sail"), a seaport of German East Africa, lying opposite the island of Pemba in 5° 6′ S., 39° 7′ E. The town is regularly laid out on elevated ground on the southern shore of Tanga Bay, and has a population of about 6000. Among the public buildings are the administrator's residence, the hospital, the boma (barracks), Protestant and Catholic churches and the government and mission schools. Tanga is the port of the Usambara district, where are many thriving plantations. The harbour is entered by a broad channel five to eight fathoms deep. It is a port of call for the German mail steamers, and the starting-point of a railway to the Usambara highlands.

TANGANYIKA (a name said by V. L. Cameron to signify a "mixing-place"), a vast lake in East-Central Africa, the longest freshwater lake in the world, measuring just over 400 m., with a general breadth varying from 30 to 45 m., and an area of about 12,700 sq. m. It lies at an altitude of about 2600 ft. above the sea, and occupies the southern end of the great central rift-valley, which terminates suddenly at its southern point, the line of depression being represented farther south by the more easterly trough of Lakes Nyasa and Rukwa, from which Tanganyika is separated by the Fipa plateau, composed of old granitoid rocks; though even here traces of old valley-walls are said by Dr Kohlschütter to exist. North of Tanganyika the valley is suddenly interrupted by a line of ancient eruptive ridges, which dam back the waters of Lake Kivu (*q.v.*), but have been recently cut through by the outlet of that lake, the Rusizi, which enters Tanganyika by several mouths at its northern end. The flat plain traversed by the lower Rusizi was evidently once a portion of the lake floor. Tanganyika has been formed by the subsidence of a long narrow tract of country relatively to the surrounding plateaus, which fall to the lake in abrupt cliffs, some thousands of feet high in places. The geological formations thus exposed show that the plateaus are composed of a base of eruptive material, overlaid by enormous deposits of reddish sandstones, conglomerates and quartzites, exposed in parts to a depth of 2000 feet. Besides the plain to the north, a considerable area to the west, near the Lukuga outlet (see below), shows signs of having been once covered by the lake, and it is the opinion of Mr J. E. S. Moore that the sandstone ridges which here bound the trough have been recently elevated, and have been cut through by the Lukuga during the process.

The past history of the lake has long been a disputed question, and Mr Moore's view that it represents an old Jurassic arm of the sea is contested by other writers. This idea originated in the discovery of a jelly-fish, gasteropods, and other organisms of a more or less marine type, and presenting some affinity with forms of Jurassic age. This fauna, to which the term "halolimnic" has been applied, was known to exist from specimens obtained by Mr E. C. Hore and other early travellers, but has been more systematically studied by Mr Moore (during expeditions of 1896 and 1898–99) and Dr W. A. Cunnington (1904–5). Various considerations throw doubt on Mr Moore's theory, especially the almost entire absence of marine fossiliferous beds in the whole of equatorial Africa at a distance from the sea, of any remains of Jurassic faunas which might link the Tanganyika forms with those of undoubted Jurassic age in neighbouring regions. The formation of the existing rift-valley seems in any case to date from Tertiary times only.

Although drinkable, the water of the lake seems at times at least to be very slightly brackish, and it was supposed by some that no outlet existed until, in 1874, Lieutenant Cameron showed that the surplus water was discharged towards the upper Congo by the Lukuga river, about the middle of the west coast. The outlet was further examined in 1876 by Mr (afterwards Sir Henry) Stanley, who found that a bar had formed across the outlet, and it has since been proved that the outflow is intermittent, ceasing almost entirely after a period of scanty rainfall, and becoming again established when the lake-level has been raised by a series of rainy years. About 1880 it was running strongly, but about this time a gradual fall in the lake-level set in, and was continued, with occasional pauses, for some twenty years, the amount being estimated by Wissmann at 2 feet annually. In 1896 Captain H. Ramsay found that a wide level plain, which had before been covered by water, intervened between Ujiji and the lake, but stated that no further sinking had taken place during the two previous years. Near Tembwe Head Mr L. A. Wallace found recent beaches 16 feet above the existing level. The Lukuga was reported blocked by a bar about 1897, but a certain amount of water was found flowing down by Mr Moore in 1899; while in 1901 Mr Codrington found the level 4 or 5 feet higher than in 1900, the outlet having again silted up. A continued rise was also reported in 1907. In any case, the alterations in level appear to be merely periodic, and due to fluctuations in rainfall, and do not point, as some have supposed, to a secular drying up of the lake.

The lake is fed by a number of rivers and small streams which descend from the surrounding highlands. The Mlagarazi (or Malagarasi), perhaps the largest feeder, derives most of its water from the rainy districts east of the strip of high ground which shuts in the lake on the north-east. The main stream, in fact, has a nearly circular course, rising in 4° 40′ S., only some 10 miles from the lake shore and less than 40 miles from its mouth, though its length is at least 220 miles. The other branches of the Mlagarazi, which traverse the somewhat arid granite plateaus between the lake and 33° E., bring comparatively little water to the main stream. In its lower course the river is a rapid stream flowing between steep jungle-clad hills, with one fall of 50 feet, and is of little use for navigation. The various channels of its delta are also obstructed with sand-banks in the dry season. The Rusizi, the next (or perhaps equal) in importance among the feeders of the lake, has already been spoken of. It receives many tributaries from the sides of the rift-valley, and is navigable for canoes. The remaining feeders are of distinctly less importance, the Lofu, which enters in the south-west, being probably the largest.

Tanganyika has never been sounded systematically, but the whole configuration of its valley points to its being generally deep, and this has been confirmed by a few actual measurements. Dr Livingstone obtained a depth of 326 fathoms opposite Mount Kabogo, south of Ujiji. Mr Hore often failed to find bottom with a line of 168 fathoms. The French explorer, Victor Giraud, reported 647 metres (about 350 fathoms) off Mrumbi on the west coast, and Moore depths of 200 fathoms and upwards near the south end. The shores fall rapidly as a rule, and there is a marked scarcity of islands, none occurring of any size or at a distance from the coast line. The lake is subject to occasional storms, especially from the south-south-east and south-west, which leave a heavy swell and impede navigation. The cloud and thunder and lightning effects are spoken of as very impressive, and the scenery of the lake and its shores has been much extolled by travellers.

Vegetation is generally luxuriant, and forest clothes portions of the mountain slopes. The lake lies on the dividing line between the floral regions of East and West Africa, and the oil-palm characteristic of the latter is found on its shores. The largest timber tree is the mvule, which attains vast dimensions, its trunk supplying the natives with the dug-out canoes with which they navigate the lake. The more level parts of the shores have a fertile soil and produce a variety of crops, including rice, maize, manioc, sweet potatoes, sugar-cane, &c., &c. The waters display an abundance of animal life, crocodiles and hippopotami occurring in the bays and river mouths, which are also the haunts of water-fowl of many kinds. Fish are also plentiful. Various sections of the Bantu division of the Negro race dwell around the lake, those on the west and south-west showing the most pronounced Negro type, while the tribes on the east exhibit some intermixture with representatives of the Hamitic stock, and (towards the south) some traces of Zulu influence. The surrounding region has been overrun by Arabs and Swahili from the East African coast.

Though rumours of the existence of the lake had previously reached the east coast, Tanganyika was not visited by any European until, in 1858, the famous expedition of Burton and Speke reached the Arab settlement of Ujiji and partially explored the northern portion. Ujiji became famous some years later as the spot where Dr Livingstone was found by Stanley in 1871, after being lost to sight for some time in the centre of the continent. The southern half of the lake was first circumnavigated by Lieutenant V. L. Cameron in 1874, and the whole lake by Stanley in 1876. The mapping of Tanganyika, which long rested on the surveys of Mr E. C. Hore, published in 1882, received considerable modification, about 1899–1900, from the work of Fergusson, Lemaire, Kohlschütter and others, who showed that while the general outline of the coasts had been drawn fairly correctly, the whole central portion, and to a lesser degree the northern, must be shifted a considerable distance to the west. At Mtowa, in 5° 43′ S., the amount of shifting of the west coast was about 30 miles. At Ujiji, on the east coast, the longitude was given by Kohlschütter as 29° 40′ 2″ E. as compared with 30° 4′ 30″ E. of Cameron, a difference of some 25 miles.

In the partition of Africa among the European Powers, the shores of Tanganyika have been shared by Belgium, Great Britain and Germany, Great Britain holding the southern extremity, Germany the east, and Belgium the west. Stations have been established on the lake by all three Powers, the principal being—German: Bismarckburg in the south and Ujiji in the north; British: Sumbu and Kasakalawe, on Cameron Bay; Belgian: Mtowa or Albertville in 6° S. Missionaries, especially the Catholic "White Fathers," are also active on its shores. A small steamer, the "Good News," was placed on the lake by the London Missionary Society in 1884, but afterwards became the property of the African Lakes Corporation; a larger steamer, the "Hedwig von Wissmann," carrying a quick-firing Krupp gun, was launched in 1900 by a German expedition under Lieutenant Schloifer; and others are owned by the "Tanganyika Concessions" and Katanga companies. The greater part of the trade with Tanganyika is done by the African Lakes Corporation by the Shiré-Nyasa route, but the Germans have opened up overland routes from Dar-es-Salaam.

TANGERMÜNDE, a town of Germany, in the Prussian province of Saxony, on the Elbe, 43 m. N.E. from Magdeburg by rail *via* Stendal. Pop. (1905) 12,829. It contains iron foundries, shipbuilding yards, refineries, and other industrial establishments, and enjoys a considerable river trade in grain and coal. It is ornamented by numerous brick buildings of the 14th and 15th centuries, including the turreted walls, the church of St Stephen (1376), and the late Gothic town hall. The castle, built in the 14th century, was the chief residence of the margraves of Brandenburg.

See Götze, *Geschichte der Burg Tangermünde* (Stendal, 1871).

TANGIER (locally Tanjah), a seaport of Morocco, on the Straits of Gibraltar, about 14 m. E. of Cape Spartel, nestles between two eminences at the N.W. extremity of a spacious bay. The town, which has a population of about 40,000, presents a picturesque appearance from the sea, rising gradually in the form of an amphitheatre, with the citadel, the remainder of the English mole and York Castle to the right: in the central valley is the commercial quarter, while to the left along the beach runs the track to Tetuan. Though rivalry between European Powers led to many public works being delayed, through the action of the public Sanitary Association the streets, which are narrow and crooked, have been re-paved as well as cleaned and partially lighted, and several new roads have been made outside the town. In some of the older streets European shops have replaced the picturesque native cupboards; drinking dens have sprung up at many of the corners, while telephones and electric light have been introduced by private companies, and European machinery is used in many of the corn-mills, &c. The main thoroughfare leads from Báb el Marsa (Gate of the Port) to the Báb el Sok (Gate of the Market-place) known to the English as Port Catherine. The sok presents a lively spectacle, especially upon Thursdays and Sundays.

Tangier is almost destitute of manufactures, and while the trade, about £750,000 a year, is considerable for Morocco, it is confined chiefly to imports, about two-fifths of which come from Great Britain and Gibraltar, and one quarter from France. The exports are chiefly oxen, meat, fowls and eggs for Gibraltar and sometimes for Spain, with occasional shipments of slippers and blankets to Egypt. Most of the trade, both wholesale and retail, is in the hands of the Jews (see further Morocco).

The harbour formed by the Bay of Tangier is an extensive one, the best Morocco possesses, and good in all weathers except during a strong east wind, but vessels of any size have to anchor a mile or so out as the shore to the west is shallow and sandy, and to the east, rocky and shingly. Since 1907 a basin with an outer and inner mole has been built. It does not, however, accommodate large vessels. The climate is temperate and healthy, and good for consumptives.

As the seaport nearest to Europe, Tangier is the town in the empire in which the effects of progress are most marked, and since the end of the 18th century it has been the diplomatic headquarters. The nucleus of a cosmopolitan society thus formed has expanded into a powerful community enjoying privileges and immunities unknown to natives not receiving its protection. The steadily increasing number of visitors has induced the opening of first-class hotels, and necessitated extensive building operations, resulting in the immigration of some thousands of artisans, chiefly Spanish. The number of European inhabitants (1905) was about 9000 (7500 Spaniards); of Jews about 10,000.

The Roman Tingis, which stood in the immediate vicinity of the site of Tangier, was of great antiquity; under Augustus it became a free city, and when Otho placed the western half of Mauretania under a procurator, he called it Mauretania Tingitana after its capital Tingis. It was held by Vandals, Byzantines and Arabs, and when Mulai Idris passed from Tlemçen to Fez in 788, Tangier was "the oldest and most beautiful city" of the Maghrib. After many futile attempts the Portuguese obtained possession of it in 1471, but it passed to Spain in 1580, returning again to the Portuguese in 1656. In 1662 as part of the dowry of Catherine of Braganza on her marriage to Charles II., it came into the possession of the English, and they defended it against Mulai Ismail in 1680, but in 1684 it was decided, on account of expense, to abandon the place to the Moors. El Ufrani writes that "it was besieged so closely that the Christians had to flee on their vessels and escape by sea, leaving the place ruined from bottom to top." It was bombarded in 1844 by the French, then at war with Morocco. In the early years of the 20th century the sharīf Raisūli terrorized the district round Tangier and made captive several Europeans. As one result of the Algeçiras conference of 1906 a regular police force was organized, and the control of the customs passed into European hands (see MOROCCO: § *History*).

See A. Cousin, *Tanger* (Paris, 1902); *Archives Marocaines* (Paris, 1904–6).

TANGYE, SIR RICHARD (1833–1906), British manufacturer, was born at Illogan, near Redruth, Cornwall, on the 24th of November 1833, the son of a small farmer. As a young boy he worked in the fields, but when he was eight years old he was incapacitated from further manual labour by a fracture of the right arm. His father then determined to give him the best education he could afford, and young Tangye was sent to the Friends' School at Sidcot, Somersetshire, where he progressed rapidly and became a pupil-teacher. Tangye was not long contented with this position, and through an advertisement in *The Friend* obtained a clerkship in a small engineering firm in Birmingham, where two of his brothers, skilled mechanics, subsequently joined him. Here Richard Tangye remained four years, obtaining a complete mastery of the details of an engineering business, and introducing the system of a Saturday half-holiday which was subsequently adopted in all English industrial works. In 1856 he started business in a small way in Birmingham as a hardware factor and commission agent. His first customers were the Cornish mine-owners in the Redruth district, and, the business prospering, he was able before long to start manufacturing hardware goods on his own account, his two brothers joining him in the enterprise. The speciality of the brothers Tangye was the manufacture of machinery, and their hydraulic lifting jacks were successfully employed in the launching of the steamship "Great Eastern." In 1858 the firm, who now confined themselves to making machinery, built their own works, and shortly afterwards secured the sole right of manufacturing the newly invented differential pulley-block, thereby materially adding to their business, which came to include every kind of power-machine—hydraulic, steam, gas, oil and electricity. The business was subsequently turned into a limited company, and in 1894 Richard Tangye was knighted. He died on the 14th of October 1906.

TANISTRY (from Gaelic *tana*, lordship), a custom among various Celtic tribes, by which the king or chief of the clan was chosen from among the heads of the septs and elected by them in full assembly. He held office for life and was required by custom to be of full age, in possession of all his faculties and without any remarkable blemish of mind or body. At the same time, and subject to the same conditions, a *tanist* or next heir to the chieftaincy was elected, who if the king died or became disqualified, at once became king. Usually the king's son became tanist, but not because the system of primogeniture was in any way recognized; indeed, the only principle adopted was that the dignity of chieftainship should descend to the eldest and most worthy of the same blood. These epithets, as Hallam says, were not necessarily synonymous, but merely indicated that the preference given to seniority was to be controlled by a due regard to desert (*Constit. Hist.*, vol. iii. c. xviii.). This system of succession left the headship open to the ambitious, and was a frequent source of strife both in families and between the clans. Tanistry was abolished by a legal decision in the reign of James I. and the English land system substituted.

TANJÓRE, a city and district of British India in the Madras presidency. The city is situated on the right bank of the river Cauvery, and is an important junction on the South Indian railway, 218 m. S. of Madras. Pop. (1901) 57,870. As the last capital of the ancient Hindu dynasty of the Cholas, and in all ages one of the chief political, literary and religious centres of the south, the city is full of interesting associations. It was the scene of the earliest labours of Protestant missionaries in India. The modern history of Tanjore begins with its conquest by the Mahrattas in 1674 under Venkaji, the brother of Sivaji the Great. The British first came into contact with Tanjore by their expedition in 1749 with a view to the restoration of a deposed raja. In this they failed, and a subsequent expedition was bought off. The Mahrattas practically held Tanjore until 1799. In October of that year the district was ceded to the East India Company in absolute sovereignty by Raja Sharabhoji, pupil of the missionary Schwarz. The raja retained only the capital and a small tract of country round. He died in 1833 and was succeeded by his son Sivaji, on whose death in 1855 without an heir the house became extinct. The mission at Tanjore was founded in 1778 by the Rev. Christian F. Schwarz or Schwartz (1726–1798). The mission establishments were taken over in 1826 by the Society for the Propagation of the Gospel, which subsequently founded new stations in several parts of the district. Roman Catholic missions date from the first half of the 17th century. St Peter's College, founded by Schwarz as a school, is now a first-grade college affiliated to the university of Madras. His church dates from 1779. Among interesting ancient buildings may be mentioned the palace within the fort, containing an armoury and fine library; and the Brihadiswaraswami temple, of the 11th century, enclosed in two courts, surmounted by a lofty tower and including the exquisitely decorated shrine of Subrahmanya. Though the city has specialities of jewelry, carpets, modelling in pith, &c., there are no large industries.

The DISTRICT OF TANJORE has an area of 3710 sq. m. On account of its fertility it has been called the "Garden of Southern India." It is irrigated by an elaborate system of dams, cuts and canals in connexion with the rivers Cauvery and Coleroon, and the soil is exceedingly productive. The delta of the Cauvery occupies the flat northern part, which is highly cultivated, dotted over with groves of coco-nut trees, and is one of the most densely populated tracts in India. The staple crop is rice, which is grown on 77 per cent. of the cultivated area. Tanjore is a land of temples, many of them being of very early date. The district is traversed by the main line and several branches of the South Indian railway, some of which have been constructed by the district board. The chief seaport is Negapatam, and the principal export is rice to Ceylon. The population in 1901 was 2,245,029.

See *Tanjore District Gazetteer* (Madras, 1906).

TANKARD, a type of drinking vessel. The word was formerly used loosely of many sizes, usually large, of vessels for holding liquids; thus it was applied to such as held two or more gallons and were used to carry water from the conduits in London in the 16th and early 17th centuries. The word is now generally applied to a straight, flat-bottomed drinking vessel of silver, pewter or other metal, or of glass or pottery mounted on metal, with a hinged cover and handle, holding from a pint to a quart of liquor (see DRINKING VESSELS). The derivation is obscure. It appears in O. Fr. as *tanquart* and in O. Du. as *tanckaert*. It may have been, as is suggested, metathesized from Gr. *κάνθαρος*, Lat. *cantharus*, a large vessel or pot. It is used to gloss *amphora* in the *Promptorium Parvulorum* (*c.* 1440). It is not connected with "tank," a cistern or reservoir for water, which was formerly "stank," and is from Port. *tanque*, O. Fr. *estang*, mod. *étang*, pool; Lat. *stagnum*, whence Eng. "stagnant."

TANNA (Aramaic, "teacher"). The root *teni* or *tena* corresponds philologically to the Hebrew *shana*, from which comes the word *Mishnah* (see MIDRASH and TALMUD), the great Rabbinic code which (with certain parts of the Midrash and other Rabbinic books) was the main literary product of the activity of the *tannaim* (plural of *tanna*). The term *tanna* is used in the Talmud of those teachers who flourished in the first two centuries of the Christian era. The *tannaim* from the date of the destruction of the Temple may be grouped: (1) 70–100, representative name Johanan ben Zaqqai (*q.v.*); (2) 100–130, representative name Aqība (*q.v.*); (3) 130–160, representative name Judah the Prince, compiler of the *Mishnah*. The successors of the *tannaim* were called *'amoraim* (see 'AMORA).

See W. Bacher, *Die Agada der Tannaiten*. An alphabetical list of tannaim and 'amoraim is given in the *Jewish Encyclopedia*, xii. 49–54. (I. A.)

TANNAHILL, ROBERT (1774–1810), Scottish song-writer, son of a Paisley silk-weaver, was born on the 3rd of June 1774. He was apprenticed to his father's trade at the age of twelve, and, inspired by the poetry of Robert Burns, he wrote verses as he drove the shuttle to and fro, with shelf and ink-bottle rigged up on his loom-post. He was shy and reserved, of small and delicate physique, and took little part in the social life of the town. The steady routine of his trade was broken only by occasional excursions to Glasgow and the land of Burns, and a year's trial of work at Bolton. He began in 1805 to contribute verses to Glasgow and Paisley periodicals, and published an edition of his poems by subscription in 1807. Three years later, on the 17th of May 1810, the life of the quiet, gentle, diffident and despondent poet was brought by his own act to a tragic end. Tannahill's claims to remembrance rest upon half a dozen songs, full of an exquisite feeling for nature, and so happily set to music that they have retained their popularity. "Loudon's Bonnie Woods and Braes," "Jessie, the Flower o' Dunblane," and "Gloomy Winter's Noo Awa" are the best of them. "Jessie, the Flower o' Dunblane" and "The Farewell" tell the story of the poet's own unhappy love for Janet Tennant.

Tannahill's centenary was celebrated at Paisley in 1874. See edition by D. Semple (1876) for details of his life.

TANNER, HENRY OSSAWA (1859–), American artist, of negro descent, was born at Pittsburg, Pennsylvania, on the 21st of June 1859. He was the son of Benjamin Tucker Tanner (b. 1835), who became bishop of the African Methodist Episcopal Church in 1888, edited the *Christian Recorder*, the organ of his church, from 1867 to 1883, founded, and from 1884 to 1888 edited, the *African Methodist Episcopal Church Review*, and published several pamphlets, poems and hymns, and an *Apology for African Methodism* (1867). The son was a pupil of Thomas Eakins, in Philadelphia, and of J. P. Laurens and Benjamin Constant in Paris. He first exhibited at the Salon in 1895. His "Daniel in the Lions' Den" received an honourable mention at the Salon of 1896. "The Raising of Lazarus," which received a third-class medal in 1897, was purchased by the French government for the permanent collection of the Luxembourg. Other pictures are, "The Annunciation" (Salon, 1898), "Nicodemus Coming to Christ" (1899), "The Jews' Wailing Place," and "Christ in the Temple."

TANNER, THOMAS (1674–1735), English antiquary and prelate, was born at Market Lavington in Wiltshire on the 25th of January 1674, and was educated at Queen's College, Oxford, taking holy orders in 1694. Next year he became chaplain and then fellow of All Souls College, and a few years later private chaplain to John Moore (1646–1714), bishop of Norwich and afterwards of Ely, who appointed him chancellor of the diocese of Norwich. In 1706 he became rector of Thorpe, near Norwich, in 1713 a canon of Ely, in 1724 a canon of Christ Church, Oxford, and in 1732 bishop of St Asaph. He died in Oxford, where he had passed most of his life, on the 14th of December 1735.

Tanner's chief work is his *Notitia Monastica*, a short account of all the religious houses in England and Wales. This was published at Oxford in 1695; it was reprinted with additions by the author's brother, John Tanner, in 1744; and was reprinted again with further additions by James Nasmith (1740–1808) in 1787. He also wrote *Bibliotheca Britannico-Hibernica*, a dictionary of all the authors who flourished in England, Scotland and Ireland before the opening of the 17th century, at which he laboured for forty years. This was not published until 1748, thirteen years after the author's death. The bishop collected materials for a history of Wiltshire and worked for some time on a new edition of the works of John Leland. His valuable collection of books and manuscripts is in the Bodleian library at Oxford.

Another writer of this name was THOMAS TANNER (1630–1682), the author of *The Entrance of Mazzarini* (Oxford, 1657–58). Educated at St Paul's School, London, and at Pembroke Hall, Cambridge, he became a barrister and later a clergyman, being vicar of Colyton, Devon, and afterwards of Winchfield, Hants.

TANNHÄUSER, or TANHUSER, German Minnesinger of the 13th century, who lived for a time at the court of Frederick II., duke of Austria. After Duke Frederick's death he was received at the court of Otto II., duke of Bavaria; but, being of a restless disposition, and having wasted his fortune, he spent much time in wandering about Germany. He also went as a Crusader to the Holy Land. His poems belong to the decadence of the Minnesang, and combine a didactic display of learning with descriptions of peasant-life in a somewhat coarse tone. His adventurous life led him to be identified, in the popular imagination, with the knight Tannhäuser who, after many wanderings, comes to the Venusberg, or Hörselberg, near Eisenach. He enters the cave where the Lady Venus—the Frau Hulda of German folk-lore—holds her court, and abandons himself to a life of sensual pleasure. By and by he is overcome by remorse, and, invoking the aid of the Virgin Mary, he obtains permission to return for a while to the outer world. He then goes as a pilgrim to Rome, and entreats Pope Urban to secure for him the forgiveness of his sins. The pope declares it is as impossible for him to be pardoned as for the staff he has in his hand to blossom. Tannhäuser departs in despair, and returns to the Venusberg. In three days the staff begins to put forth green leaves, and the pope sends messengers in all directions in search of the penitent, but he is never seen again. This legend was at one time widely known in Germany, and as late as 1830 it survived in a popular song at Entlebuch in Switzerland, a version of which was given by Uhland in his *Alte hoch- und niederdeutsche Volkslieder*. Among the attendants of Hulda was the faithful Eckhart, and in the preface to the *Heldenbuch* he is said to sit before the Venusberg, and to warn passers-by of the dangers to which they may be exposed if they linger in the neighbourhood. The legend has been reproduced by several modern German poets, and by R. Wagner in an opera.

For Tannhäuser's lyric poetry, see F. H. von der Hagen's *Minnesinger*, ii. (1838); K. Bartsch, *Deutsche Liederdichter des 12. bis 14. Jahrhunderts* (3rd ed. 1893), No. 47. See also F. Zander, *Die Tannhäusersage und der Minnesinger Tannhäuser* (1858); J. G. T. Grässe, *Die Sage von Tannhäuser* (1846; 2nd ed. 1861); A. Öhlke *Zu Tannhäusers Leben und Dichten* (1890); J. Siebert, *Tannhäuser, Inhalt und Form seiner Gedichte* (1894).

TANNIN, or TANNIC ACID, the generic name for a widely disseminated group of vegetable products, so named from their property of converting raw hide into leather (*q.v.*). They are soluble in water, their solutions having an acid reaction and an astringent taste; the solutions are coloured dark blue or green by ferrous salts, a property utilized in the manufacture of ink (*q.v.*). Their chemistry is little known. Some appear to be glucosides of gallic acid, since they yield this acid and a sugar on hydrolysis, *e.g.* oak tannin; whilst others yield protocatechuic acid and phloroglucin, *e.g.* moringa-tannin; common tannin, however, is a digallic acid.

Common tannin, or tannic acid, $C_{14}H_{10}O_9 \cdot 2H_2O$, occurs to the extent of 50% in gall-nuts, and also in tea, sumach and in other plants. It may be obtained by extracting powdered gall-nuts with a mixture of ether and alcohol, whereupon the tannin is taken up in the lower layer, which on separation and evaporation yields the acid. When pure the acid forms a colourless, amorphous mass, very soluble in water, less so in alcohol, and practically insoluble in ether. Common salt precipitates it from aqueous solutions. It forms a penta-acetate. It may be obtained artificially by heating gallic acid with phosphorus oxychloride or dilute arsenic acid (cf. P. Biginelli, *Gazetta*, 1909, 39, ii. pp. 268 *et seq.*); and conversely on boiling with dilute acids or alkalis it takes up a molecule of water and yields two molecules of gallic acid, $C_7H_6O_5$. It is optically active—a fact taken account of in J. Dekker's formula (*Ber.*, 1906, 39, p. 2497). The chemistry has also been investigated by M. Nierenstein and L. F. Iljin (see papers in the *Ber.*, 1908, *et seq.*).

The tannin of oak, $C_{19}H_{16}O_{10}$, which is found, mixed with gallic acid, ellagic acid and quercite, in oak bark, is a red powder; its aqueous solution is coloured dark blue by ferric chloride, and boiling with dilute sulphuric acid gives oak red or phlobaphene. The tannin of coffee, $C_{30}H_{18}O_{16}$, found in coffee beans, is not precipitated from its solutions by gelatin. Hydrolysis by alkaline solutions gives a sugar and caffeic acid; whilst fusion with potassium hydroxide gives protocatechuic acid. Moringa-tannin or maclurin, $C_{13}H_{10}O_6 \cdot H_2O$, found in *Morus tinctoria*, hydrolyses on fusion with caustic potash to phloroglucin and protocatechuic acid. Catechu-tannin occurs in the extract of *Mimosa catechu*; and kino-tannin is the chief ingredient of kino (*q.v.*).

MEDICINE.—Tannic acid is official in both the British and United States Pharmacopoeias. It is incompatible with mineral acids, alkalis, salts of iron, antimony, lead and silver, alkaloids and gelatin. The British pharmacopoeial preparations are (1) *glycerinum acidi tannici*; (2) *suppositoria acidi tannici*; (3) *trochiscus acidi tannici*. The United States also has a *collodium stypticum* and an ointment. From tannic acid is also made *gallic acid*, which resembles tannic acid but has no astringent taste. When applied to broken skin or exposed surfaces it coagulates the albumen in the discharges, forming a protecting layer or coat. It is moreover an astringent to the tissues, hindering the further discharge of fluid. It is a powerful local haemostatic, but it only checks haemorrhage when brought directly in contact with the bleeding point. It is used in the treatment of haemoptysis in the form of a fine spray, or taken internally it will check gastric haemorrhage. In large doses, however, it greatly disorders the digestion. In the intestine tannic acid controls intestinal bleeding, acting as a powerful astringent and causing constipation; for this reason it has been recommended to check diarrhoea.

Tannic acid is largely used in the treatment of various ulcers, sores and moist eruptions. The glycerin is used in tonsillitis and the lozenges in pharyngitis. For bleeding haemorrhoids tannic acid suppositories are useful, or tannic acid can be dusted on directly. The collodium stypticum is a valuable external remedy. Tannic acid is absorbed as gallic acid into the blood and eliminated as gallic and pyrogallic acids, darkening the urine. Gallic acid does not coagulate albumen when used externally. It has been used internally in haemoptysis and haematuria. Combined with opium it is an efficient remedy in *diabetes insipidus*.

TANN-RATHSAMHAUSEN, LUDWIG SAMSON ARTHUR, FREIHERR VON UND ZU DER (1815–1881), Bavarian general, was born at Darmstadt on the 18th of June 1815, the day of Waterloo. He was descended from the old family of von der Tann, which had representatives in Bavaria, Alsace and the Rhine countries, and assumed his mother's name (she being the daughter of an Alsatian, Freiherr von Rathsamhausen) in 1868 by licence of the king of Bavaria. Ludwig, the first king of Bavaria, stood sponsor for the child, who received his name and in addition that of Arthur, in honour of the duke of Wellington. He received a careful education, and in 1827 became a page at the Bavarian court, where a great future was predicted for him. Entering the artillery in 1833, he was after some years placed on the general staff. He attended the manoeuvres of the Austrian army in Italy under Radetzky (*q.v.*) and, in the spirit of adventure, joined a French military expedition operating in Algiers against the Tunisian frontier. On his return he became a close personal friend of the Crown Prince Maximilian Joseph (afterwards King Maximilian). In 1848 he was made a major, and in that year he distinguished himself greatly as the leader of a Schleswig-Holstein light corps in the Danish war. At the close of the first campaign he was given the order of the Red Eagle by the king of Prussia, and his own sovereign gave him the military order of Max-Joseph without his asking for it, and also made him a lieutenant-colonel. In 1849 he served as chief of staff to the Bavarian contingent at the front, and distinguished himself at the lines of Düppel, after which he visited Haynau's headquarters in the Hungarian war, and returned to Schleswig-Holstein to serve as v. Willisen's chief of staff in the Idstedt campaign. Then came the threat of war between Prussia and Austria, and von der Tann was recalled to Bavaria. But the affair ended with the "surrender of Olmütz," and he saw no further active service until 1866, rising in the usual way of promotion to colonel (1851), major-general (1855), and lieutenant-general (1861). In the earlier years of this period he was the aide-de-camp and constant companion of the king. In the war of 1866 he was chief of the staff to Prince Charles of Bavaria, who commanded the South German contingents. The almost entirely unfortunate issue of the military operations led to his being vehemently attacked in the press, but the unreadiness and unequal efficiency of the troops and the general lack of interest in the war on the part of the soldiers foredoomed the South Germans to failure in any case. He continued to enjoy the favour of the king and received promotion to the rank of general of infantry (1869), but the bitterness of his disappointment of 1866 never left him. He was grey-haired at forty-two, and his health was impaired. In 1869 von der Tann-Rathsamhausen, as he was now called, was appointed commander of the I. Bavarian corps. This corps he commanded in the Franco-German War, and therein he retrieved his place as one of the foremost of German soldiers. His gallantry was conspicuous at Wörth and Sedan. Transferred in the autumn to an independent command on the Loire, he conducted the operations against d'Aurelle de Paladines, at first with marked success, and forced the surrender of Orleans. He had, however, at Coulmiers to give way before a numerically larger French force; but reinforced, he fought several successful engagements under the Grand Duke of Mecklenburg near Orleans. On the termination of the war he was reappointed commander-in-chief of the I. Bavarian corps, a post which he held until his death at Meran on the 26th of April 1881. He had the grand cross of the Bavarian military orders, and the first class of the Iron Cross and the *pour le mérite* from the king of Prussia. In 1878 the emperor named von der Tann chief of a Prussian infantry regiment, decreed him a grant, and named one of the new Strassburg forts after him.

See Life by Lieutenant-colonel Hugo von Helvig in *Mil. Wochenblatt*, Supplement, 1882.

TANSA, a small river in Salsett island, in the Thana district of Bombay, which provides the city of Bombay with its water-supply. It is embanked by one of the largest masonry dams in the world, built in 1892. The embankment is nearly 2 m. long, 118 ft. high, and 110 ft. thick at the base.

TANTA, a town of Lower Egypt, in a central position nearly midway between the two main branches of the Nile, and converging-point of several railways traversing the Delta in all directions. It has a population (1907) of 54,437, is the capital of the rich province of Gharbia, and is noted for its fairs and Moslem festivals, which are held three times a year in honour of Seyyid el-Bedawi, and are sometimes attended by 200,000 pilgrims and traders. There are a large railway station, a very fine mosque (restored), and a palace of the khedive. Seyyid el-Bedawi, who lived in the 13th century A.D., was a native of Fez who, after a pilgrimage to Mecca, settled in Tanta. He is one of the most popular saints in Egypt.

TANTALUM [symbol Ta, atomic weight 181·0 (O=16)], a metallic chemical element, sparingly distributed in nature and then almost invariably associated with columbium. Its history is intermixed with that of columbium. In 1801 C. Hatchett detected a new element, which he named columbium, in a mineral from Massachusetts, and in 1802 A. G. Ekeberg discovered an element, tantalum, in some Swedish yttrium minerals. In 1809 W. H. Wollaston unsuccessfully endeavoured to show that columbium and tantalum were identical. In 1844 H. Rose detected two new elements in the columbites of the Bodenmais, which he named *niobium* and *pelopium; dianium* was discovered by W. X. F. von Kobell in various columbites; and *ilmenium* and *neptunium* were discovered by R. Hermann. The researches of C. W. Blomstrand, and others, especially of Marignac, proved the identity of columbium, dianium and niobium, and that ilmenium was a mixture of columbium and tantalum. It is very probable that neptunium is a similar mixture. Berzelius, who prepared tantalic acid from the mineral tantalite in 1820, obtained an impure metal by heating potassium tantalofluoride with potassium. In 1902 H. Moissan obtained a carbon-bearing metal by fusing the pentoxide with carbon in the electric furnace. The preparation of the pure metal was successfully effected by Werner von Bolton in 1905, who fused the compressed product obtained in the Berzelius process in the electric furnace, air being excluded. An alternative method consisted in passing an electric current through a filament of the tetroxide in a vacuum. The metal is manufactured, for use as filaments in electric lamps, by the action of sodium on sodium tantalofluoride.

The pure metal is silver-white in colour, is very ductile, and becomes remarkably hard when hammered, a diamond drill making little impression upon it. Its tensile strength is higher than that of steel. It melts between 2250° and 2300°, its specific heat is 0·0365, coefficient of expansion 0·0000079, and specific gravity 16·64. When heated in air the metal burns if in the form of thin wire, and is superficially oxidized if more compact. At a red heat it absorbs large volumes of hydrogen and nitrogen, the last traces of which can only be removed by fusion in the electric furnace. These substances, and also carbon, sulphur, selenium and tellurium, render the metal very brittle. Tantalum is not affected by alkaline solutions, but is disintegrated when fused with potash. Hydrofluoric acid is the only acid which attacks it. It alloys with iron, molybdenum and tungsten, but not with silver or mercury.

In its chemical relationships tantalum is associated with vanadium, columbium and didymium in a sub-group of the periodic classification. In general it is pentavalent, but divalent compounds are known.

Tantalum tetroxide, Ta_2O_4, is a porous dark grey mass harder than glass, and is obtained by reducing the pentoxide with magnesium. It is unaffected by any acid or mixture of acids, but burns to the pentoxide when heated.

Tantalum pentoxide, Ta_2O_5, is a white amorphous infusible powder, or it may be crystallized by strongly heating, or by fusing with boron trioxide or microcosmic salt. It is insoluble in all acids. It is obtained from potassium tantalofluoride by heating with sulphuric acid to 400°, boiling out with water, and decomposing the residual compound of the oxide and sulphuric acid by ignition, preferably with the addition of ammonium carbonate.

Tantalic acid, $HTaO_3$, is a gelatinous mass obtained by mixing the chloride with water. It gives rise to salts, termed the tantalates. The normal salts are all insoluble in water; the complex acid, hexatantalic acid, $H_8Ta_6O_{19}$ (which does not exist in the free state), forms soluble salts with the alkaline metals. *Pertantalic acid*, $HTaO_4$, is obtained in the hydrated form as a white precipitate by adding sulphuric acid to potassium pertantalate, $K_3TaO_8 \cdot \frac{1}{2}H_2O$, which is formed when hydrogen peroxide is added to a solution of potassium hexatantalate.

Tantalum pentafluoride, TaF_5, for a long time only known in solution, may be obtained by passing fluorine over an alloy of tantalum and aluminium, and purifying by distillation in a vacuum. It forms colourless, very hygroscopic prisms, which attack glass, slowly at ordinary temperatures, more rapidly when heated (*Ber.*, 1909, 42, p. 492). Its double salts with the alkaline fluorides are very important, and serve for the separation of the metal from columbium and titanium. *Tantalum pentachloride*, $TaCl_5$, is obtained as light yellow needles by heating a mixture of the pentoxide and carbon in a current of chlorine. By heating with sodium amalgam and separating with hydrochloric acid, the dichloride, $TaCl_2 \cdot 2H_2O$, is obtained as emerald green hexagonal crystals. The pentabromide exists, but tantalum and iodine apparently do not combine. Tantalum forms a sulphide, TaS_2, and two nitrides, TaN_2 and Ta_3N_5, have been described.

Marignac determined the atomic weight to be 181, but Henrichsen and N. Sahlbom (*Ber.*, 1906, 39, p. 2600) obtained 179·8 (H = 1) by converting the metal into pentoxide at a dull red heat.

TANTALUS, in Greek legend, son of Zeus (or Tmolus) and Pluto (Wealth), daughter of Himantes, the father of Pelops and Niobe. He was the traditional king of Sipylus in Lydia (or of Phrygia), and was the intimate friend of Zeus and the other gods, to whose table he was admitted. But he abused the divine favour by revealing to mankind the secrets he had learned in heaven (Diod. Sic. iv. 74), or by killing his son Pelops (*q.v.*) and serving him up to the gods at table, in order to test their powers of observation (Ovid, *Metam.* vi. 401). Another story was that he stole nectar and ambrosia from heaven and gave them to men (Pindar, *Ol.* i. 60). According to others, Pandareus stole a golden dog which guarded the temple of Zeus in Crete, and gave it to Tantalus to take care of. But, when Pandareus demanded the dog back, Tantalus denied that he had received it. Therefore Zeus turned Pandareus into a stone, and flung down Tantalus with Mount Sipylus on the top of him (Antoninus Liberalis, 36). The punishment of Tantalus in the lower world was famous. He stood up to his neck in water, which flowed from him when he tried to drink of it; and over his head hung fruits which the wind wafted away whenever he tried to grasp them (*Odyssey*, xi. 582). This myth is the origin of the English word "tantalize," and also of the common name "tantalus" for a set of spirit decanters kept under lock and key. Another story is that a rock hung over his head ready to fall and crush him (Euripides, *Orestes*, 5). The sins of Tantalus were visited upon his descendants, the Pelopidae. Ancient historical reminiscences and natural phenomena, especially volcanic catastrophes, are at the bottom of the legend. The tomb of Tantalus on Mount Sipylus was pointed out in antiquity, and has been in modern times identified by C. F. Texier with the great cairn beneath Old Magnesia; but Sir W. M. Ramsay inclines to a remarkable rock-cut tomb beside Magnesia.

The story of Tantalus is an echo of a semi-Greek kingdom, which had its seat at Sipylus, the oldest and holiest city of Lydia, the remains of which are still visible. There was a tradition in antiquity that the city of Tantalus had been swallowed up in a lake on the mountain; but the legend may, as Ramsay thinks, have been suggested by the vast ravine which yawns beneath the acropolis. According to S. Reinach (*Revue archéologique*, 1903), Tantalus was represented in a picture standing in a lake and clinging to the branches of a tree, which gave rise to the idea that he was endeavouring to pluck its fruit. The punishment of the overhanging rock refers to the dangerous position of the town of Tantalis below the summit of Mount Sipylus.

See Pelops, Phrygia; Sir W. M. Ramsay in *Journal of Hellenic Studies*, iii.; Frazer's *Pausanias*, iii. p. 555, v., p. 392; J. Hylén, *De Tantalo* (Upsala, 1896), who considers the story of the thirst of Tantalus in the underworld to be due to the Orphic interpolator in the Νέκυια of the *Odyssey*, and the Pandareus story to be an innovation of the Alexandrine poets. The essay contains a copious list of authorities and a history of the legend. According to V. Henry (*Revue des Études grecques*, 1892), Tantalus is the sun: the fruits which elude his grasp are the stars suspended on the tree of heaven, which disappear at the rising of the sun; the water into which the sun descends without drinking, is the sea. Tantalus's betrayal of the secrets of the gods refers to the sun unveiling the secrets of heaven; the slaying of Pelops denotes the going-down of the sun, Pelops meaning the "gray one," an epithet of the gloomy sky in which the last rays of the sun are extinguished.

TANTIA TOPI (*c.* 1819–1859), rebel leader during the Indian Mutiny, was a Mahratta Brahman in the service of Nana Sahib. He instigated the massacre of Cawnpore, and commanded at the battle of Bithur, where he was defeated by General Havelock. With the aid of the Gwalior contingent he pressed General Windham hard at Cawnpore on the 27th and 28th of November 1857, but was defeated by Sir Colin Campbell on the 6th of December. Together with the Rani of Jhansi he was besieged by Sir Hugh Rose in the Jhansi fort, but escaped and collected a force of 20,000 men which Sir Hugh defeated without relaxing the siege. This was the decisive action of the campaign in Central India, and Tantia Topi was obliged to seek refuge in the jungles of Rajputana and Bundelkhand, where he was taken by Major Meade, condemned, and executed on the 18th of April 1859. He was the only rebel leader in the Mutiny who showed any conspicuous military talent.

TAOISM, a form of religion in China, the name of which is taken from the ancient treatise called *Tâo Teh King*, supposed to be the work of the sage Lao-tsze (*q.v.*). The later characteristics of Taoism as a form of worship represent a corruption of the earlier doctrines of Lao-tsze, and the infusion of Buddhist and other ideas.

TAORMINA (ancient *Tauromenium*), a town on the E. coast of Sicily, in the province of Messina, from which town it is 30 m. S.S.W. by rail. Pop. (1901) 4110. It has come into great favour as a winter resort, especially with British and German visitors, chiefly on account of its fine situation and beautiful views. It lies on an abrupt hill 650 ft. above the railway station, and was founded by the Carthaginian Himilco in 397 B.C. for a friendly tribe of Sicels, after the destruction, by Dionysius the Elder of Syracuse, of the neighbouring city of Naxos. In 395 Dionysius failed to take it by assault on a winter's night, but in 392 he occupied it and settled his mercenaries there. In 358 the exiles from Naxos, after wandering up and down Sicily, at last found a home there. Its commanding site gave it considerable importance. It was the city at which both Timoleon and Pyrrhus first landed. During the First Punic War it belonged to the kingdom of Hiero, and after his death it enjoyed an exceptionally favoured position with regard to Rome, being like Messana and Netum, a *civitas foederata*. During the first Servile War it was occupied by Eunous and some of his followers, but was at length taken by the consul Publius Rupilius in 132. It was one of the strongholds of Sextus Pompeius, and after defeating him Augustus made it into a *colonia* as a measure of precaution, expelling some of the older inhabitants. In the time of Strabo it was inferior in population, as we should expect, to Messana and Catana; its marble, wine and mullets were highly esteemed. In A.D. 902 it was taken and burnt by the Saracens; it was retaken in 962, and in 1078 fell into the hands of the Normans.

The ancient town seems to have had two citadels; one of these was probably the hill above the town to the W. now crowned by a medieval castle, while the other was the hill upon which the theatre was afterwards constructed (E. A. Freeman, *History of Sicily*, iv. 506). There are some remains of the city walls, belonging to more than one period. It is indeed possible that one fragment of wall belongs to a period, before the foundation of the city, when the Naxians had a fortified port here (Evans in Freeman, *op. cit.*, iv. 109 n. 1). The church of San Pancrazio, just outside the modern town, is built into a temple of the 3rd century B.C., the S. wall of the cella of which is alone preserved. Inscriptions prove that it was dedicated to Serapis. The other ruins belong in the main to the Roman period. The most famous of them is the theatre, largely hewn in the rock, which, though of Greek origin, was entirely reconstructed. The seats are almost entirely gone, but the stage and its adjacent buildings, especially the wall, in two storeys, at the back, are well preserved: some of its marble decorative details were removed for building material in the middle ages, but those that remained have been re-erected. The view from the theatre is of exceptional beauty, Mount Etna being clearly seen from the summit to the base on the S.W., while to the N. the rugged outlines of the coast immediately below, and the mountains of Calabria across the sea to the N.E. make up one of the most famous views in the world. There are also remains of a much smaller theatre (the so-called Odeum), and some large cisterns; a large bath or tank which was apparently open, known as the Naumachia, measures $426\frac{1}{2}$ ft. in length and $39\frac{1}{2}$ in width: only one of its long sides is now visible, and serves as a foundation for several houses in the main street of the modern town. The aqueducts which supplied these cisterns may be traced above the town. There are remains of houses, tombs, &c., of the Roman period, and fine specimens of Romanesque and Gothic architecture in the modern town.

See Rizzo, *Guida di Taormina e dintorni*, Catania, 1902. (T. As.)

TAPACULO, the name[1] given in Chile to a bird of singular appearance—the *Pteroptochus albicollis* of ornithology, and applied in an extended sense to its allied forms, which constitute a small family, *Pteroptochidae*, belonging to the *Clamatores* division of *Passeres*, peculiar to South America. About 20

Tapaculo.

species, disposed by P. L. Sclater (*Ibis*, 1874, pp. 189–206) in 8 genera, are believed to belong to this group.

The species of the Family first made known is *Scytalopus magellanicus*, originally described in 1783 by J. Latham (*Synopsis*, iv. p. 464) as a Warbler. Even in 1836 J. Gould not unnaturally took it for a Wren, when establishing the genus to which it is now referred; but some ten years after Johannes Müller found that *Scytalopus*, together with the true Tapaculo, which was first described by Kittlitz in 1830, possessed anatomical characters that removed them far from any position previously assigned to them, and determined their true place as above given. In the meanwhile a kindred form, *Hylactes*, also first described in 1830, had been shown by T. C. Eyton to have some very exceptional osteological features, and these were found to be also common to *Pteroptochus* and *Scytalopus*. In 1860 J. Cabanis recognized the *Pteroptochidae* as a distinct Family, but made it also include *Menura* (see LYRE-BIRD), and in 1874 P. L. Sclater (*ut supra*) thought that *Atrichia* (see SCRUB-BIRD) might belong here. It was A. Garrod in 1876 and 1877 who finally divested the Family of these aliens, but until examples of some of the other genera have been anatomically examined it may not be safe to say that they all belong to the *Pteroptochidae*.

The true Tapaculo (*P. albicollis*) has a general resemblance in plumage to the females of some of the smaller Shrikes (*Lanius*), and to a cursory observer its skin might pass for that of one; but its shortened wings and powerful feet would on closer inspection at once reveal the difference. In life, however, its appearance must be wholly unlike, for it rarely flies, hops actively on the ground or among bushes, with its tail erect or turned towards its head, and continually utters various and strange notes,—some, says Darwin, are "like the cooing of doves, others like the bubbling of water, and many defy all similes." The "Turco," *Hylactes megapodius*, is larger, with greatly developed feet and claws, but is very similar in colour and habits. Two more species of *Hylactes* are known, and

[1] Of Spanish origin, it is intended as a reproof to the bird for the shameless way in which, by erecting its tail, it exposes its hinder parts. It has been sometimes misspelt "Tapacolo," as by C. Darwin, who gave (*Journal of Researches*, chap. xii.) a brief but entertaining account of the habits of this bird and its relative, *Hylactes megapodius*, called by the Chilenos "El Turco."

one other of *Pteroptochus*, all of which are peculiar to Chile or Patagonia. The species of *Scytalopus* are as small as Wrens, mostly of a dark colour, and inhabit parts of Brazil and Colombia, one of them occurring so far northward as Bogota. (A. N.)

TAPER (probably of Celtic origin, cf. Irish *tapar*, Welsh *tampr*, taper, torch), a small thin candle of tallow or wax (see CANDLE); from its early shape, in which the circumference of the top was smaller than that of the base, the word came to be used in the sense of "slender," particularly of something diminishing in size at one end. In architecture the word is used of the gradual diminishing of a spire or column as it rises. The spire tapers almost to a point, where it is terminated by a finial or vane: the column tapers only to a less diameter at the top, and as a general rule the more ancient the column the greater its diminution or taper; thus in one of the early temples at Selinus in Sicily the upper diameter is about half the lower diameter, while in the Parthenon it is about one-fifth.

TAPESTRY. The Gr. τάπης and Lat. *tapesium*, from which our word "tapestry" is descended, implied a covering to both furniture and floors, as well as curtains or wall hangings, and neither of them really defines the particular way in which such articles were made. The decorations on these Greek and

FIG. 1.—Gobelins high-warp tapestry frame, with weaver (18th century), holding in right hand (*a*) bobbin with weft thread wound round its thick end, and with his left hand taking (*e*) some of the *lisses* or strings with a loop at one end of each of them, through which a warp thread is passed, and thus pulling forward those warp threads in between which he will pass his weft. *mm* is the tapestry he has woven, which has been wound round (*p*) the cylinder. The other letters in this diagram relate to details in the frame which are of subsidiary interest. The description of them would not further elucidate the act of weaving which is here in question.

Roman coverings were effected by painting, printing, embroidery, or a method of weaving with coloured threads; and specimens and other conclusive evidence show that early Egyptians, Babylonians, Chinese, Indians, Greeks and Romans employed some at least of the means above-named.

Process of tapestry-weaving. The purpose of this article is to give some account of those decorated stuffs which are produced by weaving coloured threads on to warp threads in a manner that differs from shuttle-weaving, and at the present day is called tapestry-weaving, such for instance as is practised at the famous Gobelins and Beauvais tapestry manufactories in France. At the Gobelins, the warp threads are stretched in frames standing vertically (high warp or *haute lisse*): at Beauvais in frames placed horizontally with the ground (low warp or *basse lisse*). In the one case the worker sits up to his work, in the other he bends over it. In each he is supplied with the design according to which he weaves, and notwithstanding the varied positions the method of weaving is the same. The thread-supply of each separate colour required in the design is wound upon its appointed peg or bobbin, which is a simpler implement or tool than a loom weaver's shuttle. Fig. 1 shows a Gobelins high-warp tapestry weaver of the 18th century at work. With his left hand he is pulling above his head a few of the looped strings (*lices* or *lisses*) through which the warp threads (*chaine*) pass, so as to bring forward the particular warp threads, in between and around which he has to place the weft threads of the selected colour. In fig. 2 the workman's left hand pulls forward groups of warp threads upon the lower part of which the weaving has been finished; and with a comb-like implement in his right hand he presses down and compacts the weaving. In the story of the competition between Minerva and Arachne (*Metamorphoses*, vi. 55–69), Ovid appears to be describing this very process, and a great number of specimens of 2nd to 5th century Egypto-Roman workmanship corroborate the presumption of its existence in Ovid's time. The absence of evidence to show that loom and shuttle weaving was capable at that period of producing elaborate figured fabrics is remarkable, and supports the probability that the tapestry-weaving process was that

High and low warp frames.

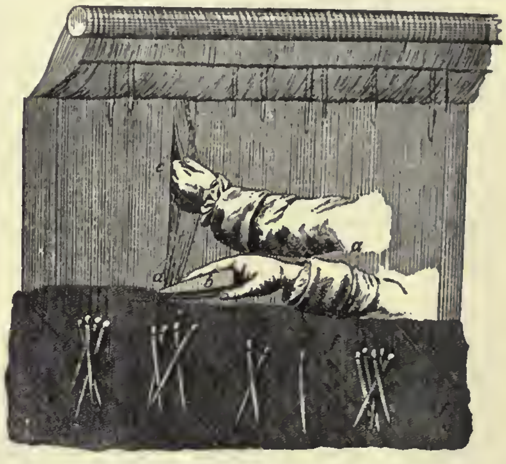

FIG. 2.—Gobelins tapestry-weaving, showing (*a*) the left hand of the weaver pulling forward (*c*) a group of warp threads, into which with (*b*) the comb in his right hand he is compressing at point (*d*) the weft threads which have been passed around and in between the warp threads; (*e*) are various bobbins, hanging at rest, suspended by their weft threads; and (*f*) is the tapestry as woven and compressed.

commonly known and practised for most if not all woven decoration and ornament. It was certainly as freely used for costumes as for hangings, couch and cushion covers and the like (see CARPET). The frames in which the work was done varied according to size from small and easily handled ones to large and substantially constructed frames. As mentioned in the article EMBROIDERY, ornament of tapestry-weaving occurs in a fragment of Egyptian work 1450 B.C., and Greeks in the 3rd or 4th century B.C. also worked in this method, as is demonstrated by specimens, now in the Hermitage at St Petersburg, which were found in the tomb of the Seven Brothers at Temriouck, formerly a Greek settlement in the province of Kouban on the north-eastern shore of the Black Sea.[1] The simplicity of the process is so obvious that it is found to be widely employed in expressing a variety of primitive textile decoration of which pieces from Borneo, Central Asia, Tibet, the Red Indians of America, and the ancient inhabitants of Peru[2] (see fig. 10) are to be seen in museums.

[2] See *Account of Graves at Ancon*, Asher & Co.; see also specimens from Graves at Lima in the Victoria and Albert Museum, London.

As regards the antiquity of the two sorts of frames (the low and high warp) the Beni Hassan wall paintings (1600 B.C.) include diagrams of horizontal (low warp) frames, with weavers squatting on the ground at work on them; while a vertical or high warp frame is represented on a Greek vase of the 5th century B.C. found at Chiusi (fig. 3), and corresponds with frames used in Scandinavian countries.[1] In both these last-named the lower ends of the warp threads are merely weighted, thus presenting

FIG. 3.—Penelope's tapestry-weaving frame, from a Greek vase of the 5th century B.C. The standing figure is that of Telemachus.

some difficulty to the act of weaving, and of subsequently compacting the weft upwards, the warp not being taut and fastened to a beam, according to more ordinary usage, as, for instance, in the high warp frame illustrated in the codex of Rabanus Maurus, 9th century A.D., preserved at Monte Cassino (fig. 4). The words "*de Geneceo*" in this illustration point to a medieval survival of the earlier *gunaikonites* of the Greeks and the *gynaecea* of the Romans, which were the quarters set apart in the house of the well-to-do for the spinning, weaving and embroidery done by women for the household. From such ancient frames to similar *haute* and *basse lisse* frames of the French *tapissiers nostrez* and *tapissiers sarrasinois* governed under edicts (1226–70) of Louis IX., and so on to present-day Gobelins and Beauvais frames, the transition can be easily realized. The texture of all tapestry weavings presents no radical difference in appearance, no matter when or where produced.

Within reasonable limits it is not practicable to sketch in a complete form the history, from the middle ages onwards, of the prosecution of the art by each of the many European towns that have become engaged in tapestry weaving. But the foregoing remarks will suggest, what seems to have been the fact, that a continuity in the knowledge of the art was kept up so that as favourable conditions occurred it would be called into practice.

Roman tapestry-weaving.

Artificers (male and female) such as the Roman *plumarii* wove tapestries with figures of Britons (Virgil, *Georg.*, iii. 25)—"*Purpurea intexti tollant aulaea Britanni,*"—others with scenes from the story of Theseus and Ariadne (Catullus, *Argon.*, xlvi. 267), besides many more for emperors and the wealthy. The demand for such production of the *textrinae* or trade workshops, and of the more private *gynaecea*, as well as the organization of workmen's societies, *collegia opificum*, are evidence of circumstances lasting for some centuries in Rome that were favourable to tapestry-weaving there. Suggestive of Roman designs are the illustrations of part of a curtain or wall hanging (fig. 5), and of a hanging or couch cover (fig. 6); whilst the daintiest quality of tapestry-weaving for the ornamentation of a tunic is displayed in fig. 7. The ornamentation in fig. 5 —a hanging 5 ft. 3 in. by 19¾ in.—consists of a series of horizontal leafy bands or garlands and other devices: between the upper bands on a red ground is a bird on a leafy twig. This is Egypto-Roman work of about the 3rd century A.D. A portion of a linen cloth or couch cover ornamented with tapestry woven in coloured wools and linen thread is shown in fig. 6. At the top there is a fragment of a horizontal border of floral and leaf ornament beneath which, and enclosed by festoons of leaves, are two boys floating in the air and holding ducks; elsewhere are figures of boys running and carrying baskets of fruit, and large and small blossom forms or rosettes. This also is Egypto-Roman work, about the 4th century, and is 4 ft. 5 in. by 4 ft. 1 in. Fig. 7 presents a square (from a small tunic) of very fine warp and weft tapestry-weaving, with a child mounted on a white horse: in the border about him are ducks, fish and (?) peaches. This too is Egypto-Roman work of about the 2nd or 3rd century and is about 4 inches square. The square in fig. 8 is from a tunic or robe and is of tapestry-weaving in bright-coloured wools, with a representation of Hermes holding the caduceus in one hand and a purse in the other. About his head is a nimbus and his name in Greek characters. This again is Egypto-Roman work of about the 1st or 2nd century and is 6½ inches square. The panel of tapestry-weaving in fig. 9 is from a couch or bed covering, and is wrought in purple wools and linen threads. The design recalls the description of the *toralia* or couch-covering alluded to in Petronius Arbiter's account of Trimalchio's banquet, "on which were depicted men in ambush with hunting poles and all the apparatus of the chase." This piece is also of Egypto-Roman work about the 2nd or 3rd century, about 12 in. by 10 in.

The well-known 6th-century Ravenna mosaics of the Emperor Justinian and the Empress Theodora are rich with hangings and costumes decorated presumably with tapestry weavings similar to those just described.

Tapestry-weaving in monasteries, 5th to 9th century.

From the 5th century and for many centuries later, monasteries,[2] nunneries and the like, under ecclesiastical control or influence, became centres of activity in this and cognate arts, stimulated by the patronage of the Church and courts; and in the 8th and 9th centuries the Emperor Charlemagne's body of travelling inspectors, *missi dominici*, appears to have exercised for a time a helpful influence upon such centres throughout France and in parts of Germany. Two centuries later, free, as distinct from bond, handicraftsmen were forming local associations for their industries, and in this movement the weavers took the lead throughout England, Flanders and Brabant, France being a little later.[3]

Gilds of weavers.

The gilds of weavers in London and Oxford were granted charters by Henry I. In the 11th century gilds of wool weavers existed at Cologne and Mainz, and in the following century there was a similar gild at Spires: it is quite probable that some of their weaving would be of tapestry.[4] The fragment in fig. 11 is considered by authorities to be of 12th-century north European work, possibly from some Rhenish place. At one time the whole piece

FIG. 4.—High warp frame from MS. Codex by Rabanus Maurus (9th century).

[4] Eugène Müntz quotes a deed (between 1164 and 1200) witnessed by "Meginwart of Welt in burch," a tapetiarius, as well as another (1177) in which mention is made of Fredericus, *tapifex de familia ecclesiae.*

FIGS. 5–9.—Specimens of Egypto-Roman tapestry weaving of about the 2nd to 5th century A.D. Victoria and Albert Museum.

TAPESTRY

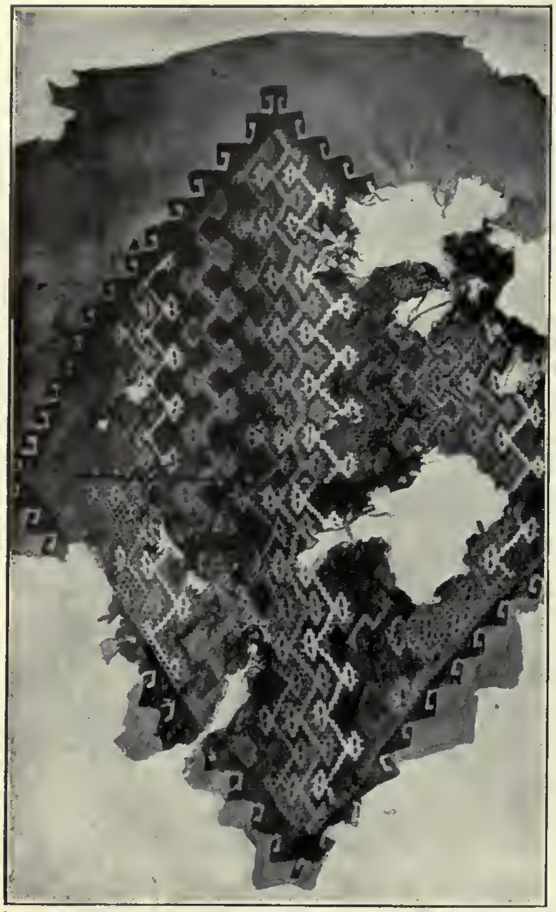

FIG. 10.—Fragment of coarse linen material with a large diamond panel of tapestry weaving in coloured threads—Peruvian-made, before the conquest of Peru by Pizarro. About 3 ft. by 2 ft. 6 in.

FIG. 11.—Portion of wall-hanging from the church of St Gereon, Cologne. North French or German manufacture of the 11th or 12th century. About 2 ft. by 2 ft. 6 in.

FIG. 12.—An antependium, or altar hanging of tapestry woven in coloured wools, with the Adoration of the Magi, probably from a design by Wohlgemuth (1434–1519). The tapestry is reputed to have been executed in a convent at Bamberg; below the folds of the Virgin's cloak, to the right, the "tapissière" has woven a figure of herself at work. German, 15th century. This interesting piece is in the museum at Munich. About 5 ft. 6 in. by 2 ft.

FIG. 13.—One of a series of designs (the Trojan War) by Jean Foucquet (1415–1485) from which tapestry hangings were woven, probably at Arras in the middle of the 15th century.

FIG. 14.—Part of the tapestry (13 ft. high) woven from the design in Fig. 13. Arrival of Queen Penthesilea at the court of King Priam.

FIG. 15.—Part of the tapestry (10 ft. high) woven from the design in Fig. 13. Queen Penthesilea overcoming Diomedes.

FIG. 16.—Long and narrow tapestry (8 ft. 10 in. by 22 in.), German work of the 15th century. Field labours, &c.

FIG. 17.—Part of a wall hanging of tapestry woven (probably at Brussels early in the 16th century) with coloured wools and silks, which is one of a series designed, probably by some member of the school of Roger van der Weyden, to illustrate the Triumphs written by Petrarch. The episode represented is the Triumph of Chastity over Love. Falling from a triumphal car fitted with flaming altars or torches of love, and drawn by four winged white horses, is Cupid, whose left arm is grasped by Chastity mounted on a unicorn and carrying the column symbolizing Strength or Constancy. Foremost in the multitude about the car of Love are Cleopatra and Julius Caesar. In another part of this hanging is the date 1507. The height of this piece is 14 ft. This, with tapestries of the Triumph of Death and Fame, is in the Victoria and Albert Museum: one hanging of the Triumph of Time is at Hampton Court.

belonged to the church of St. Gereon at Cologne; a large bit of it is now in the museum at Lyons; another at Nuremberg; whilst a small part of the border only is in the Victoria and Albert Museum, South Kensington. The pattern consists of repeated roundels within each of which is a chimerical bird and bull (? St. Luke), elsewhere is a small eagle (? St. John). The style of design, strong in oriental and Byzantine character, is frequently found in shuttle-woven silks of the period.

Tapestries from the 13th century onwards. The renaissance of literature in the 12th century, infused with romantic, mystical and religious tendencies, supplied subjects for wall decoration by fresco painting, the practice of which was revived then and came into vogue in Italy and the south, whilst its analogue in the northern and more weather-wearing countries is to be found chiefly in decorative tapestry weavings. Much tapestry is certainly indebted for its cartoons to wall painting, but illustrations in MSS. also furnished subjects from which tapestry was made by the *tapissiers nostrez* and *tapissiers de la haute lisse* in France, Germany and Flanders.[1] The earlier tapestries usually seem to have been narrow and long, *e.g.* the "*toile à broderie*" of Bayeux (see EMBROIDERY) and the 12th-century tapestries of Halberstadt cathedral. Although the making such narrow, long tapestries survived into the 14th and 15th centuries (see fig. 16), larger shapes (see figs. 14 and 15) suitable as curtains and as hangings to cover large wall-spaces became the more frequent. From this time forward the output from many European towns of big pieces, mostly woven with coloured wools, was continuous and considerable. The more sumptuous examples from the 14th to the 17th century were enriched with gleaming silks and metallic threads.[2]

Variety of designs in tapestries. The subjects of the cartoons from which tapestries were woven varied of course with the tastes of the times, the more frequent of the earlier ones being religious (see fig. 12) or illustrative of moralities. Types of romantic, legendary subjects are displayed in figs. 14 and 15 of the Siege of Troy, and fig. 23 of Dido and Aeneas. Historical design occurs in fig. 20, which is one of a set of tapestries woven possibly at the royal factory of Fontainebleau about 1540, to commemorate the fêtes on the occasion of the marriage of Henri II. with Catherine de Medicis; and again in fig. 25, of the "Glorious Defence of Londonderry." Pastoral incidents are shown in fig. 16, and social life episodes and incidents in fig. 22, which was woven at the celebrated Medici factory, Florence, in 1639 by a French weaver—Pierre Fevre—from a design in the style of F. d'Albertino (il Bacchiaca), 16th century, entitled "*L'inverno*" (winter). Less human in interest are tapestries, mostly of the late 15th century, wrought from leafy designs, usually termed "*verdures*," of which several were made at Brussels during the 16th century. Heraldic and floral devices were also frequently used, see fig. 19, from a piece of the late 15th century in Winchester College, and fig. 18, which is at Haddon Hall and was woven early in the 16th century. It is very similar to hangings which are at Bern and are said to have been captured from Charles the Bold at the battle of Granson. Many curiously designed tapestries of German 15th-century origin are to be seen in the museum at Basel—one of them (fig. 21) displays strange beasts, unicorns, stags in the midst of Gothic foliage, and labels with legends. Other tapestries, worked from still later phases of ornamental design, are fantastic with schemes of abstract ornament into which are introduced as subsidiary details figure subjects set in panels and medallions.

The treatment of the compositions in cartoons for tapestry follows that adopted by painters. Thus examples from the 11th to the end of the 15th century are formal in the drawing of the forms introduced into them, and comparatively limited in range of colours, lights and shades, in accordance with the mannerisms of the earlier painters whether illuminators of MSS. or wall and panel painters. It has been argued from this that the designers of such early tapestry work possessed a sense of the limitations imposed by the process and materials. But in their day the relatively small number of dyes available involved conventionality in colour, quite as much as the earlier styles of drawing involved conventionality in form.

Fig. 13 is from an interesting design by Jehan Foucquet (1415–1485): and is one of a set, made by him to illustrate the Trojan War, now in the Louvre. From these drawings tapestries were woven at Arras probably in the middle of the 15th century. One of these hangings in the Victoria and Albert Museum (see figs. 14 and 15) is from Foucquet's design, representing the arrival of Queen Penthesilea and her warrior women at Troy and the part she took in a fight in which she vanquished Diomedes. This episode was introduced by Quintus Calaber (or Smyrnaeus), a 4th-century writer, in his version of the Homeric story. A tapestry from another of Foucquet's designs displaying King Priam in the midst of his court is in the Palais de Justice at Issoire.

Introduction of realism in designs for tapestries. When Raphael, master of a freer and more realistic style in rendering form and colour, produced his cartoons of the Acts of the Apostles for a set of hangings for Pope Leo X., a new condition naturally came into play, and practically became a principal source of the contrast which is observable between the designs of tapestries made before his time and those made after the early part of the 16th century. The provision of a bigger scale of dyes for the wools and silks was stimulated to secure success in weaving these more realistic representations of forms and greater subtleties in colour, as well as the developed effects of perspective: compare, for instance, the treatment in fig. 14 with that in fig. 22. The restraint or limitations of the earlier styles were thus gradually supplanted by the comparative complexities of the later; and it is a point of interest to note that provision for still further inventing and improving dyes and so helping tapestry to assimilate to painting is specially included in the regulations (1667) of the state manufactory of the Gobelins, where under M. Chevreul (director of the dye-works for more than fifty years during the 19th century) 14,400 tones of colour have been used.

Sizes of borders indications of date. A chronological succession of styles may also be traced in the borders enclosing such varieties of design as those just referred to. As a rule borders consisting of a selvage or plain band come first (see fig. 12), followed by those in which labels with block-letter legends (figs. 14 and 15 and fig. 17) are features; after them are narrow borders filled in with closely and well-arranged floral forms (see lower border in fig. 17), to which succeed borders of greater width containing elaborate detail (fig. 20). Such as these date from soon after the beginning of the 16th century, and those rather wider and more extravagant in ornament follow on somewhat later (see figs. 22 and 23). In the 18th century massive rococo proscenium frames, as in fig. 25, are sometimes adopted.

Notable centres of the industry. Of the notable centres where the industry of tapestry-weaving has been in considerable practice, Arras in the 14th and 15th centuries, Brussels in the 15th and 16th, Middelburg and Delft in the late 16th and early 17th centuries,[3] Paris in the 16th and 17th centuries and down to the present time, with Mortlake in the 17th century, probably stand foremost; and from them the services of experienced workmen equipped with frames and implements were requisitioned and secured at most of the short-lived contemporaneous centres in almost all parts of Europe. Several names of tapestry-weavers working during the first half of the 14th century in Arras, Paris, Valenciennes, St. Omer and Reims, for Burgundian, Flemish and French nobles, have been recorded.[4] Throughout that century a few weavers and many tapestries came from Arras into England, where the term "arras" became the generic name for woven wall-hangings. Arras tapestries also went in quantities into Italy where they were called "*Arazzi*," and into Spain where they bore the name "*pannos de raz*." The tapicers of London received their statutes in 1331, and Edward III. caused an inquiry to be held into the *mistera tapiciariorum*.[5] The industry at Arras began to decline soon after 1460, and was succeeded about this date by works at Bruges, Ghent, Tournai, Lille, Oudenarde, but more especially at Brussels, at which last city the industry grew to an importance even greater than it had enjoyed previously at Arras or elsewhere. The regulations of the Brussels corporation of *tapissiers* were framed in 1451. Under them *tapissiers* might draw for one another the stuffs of hangings or of costumes in their figure compositions, trees, animals, boats, grasses, &c., in their "*verdures*," or leafy

---

[1] Guiffrey's *Nicolas Bataille* contains particulars of the loan by Charles V. of France to his brother Louis, duke of Anjou, of an illuminated MS. from which Hennequin or Jean of Bruges, painter in ordinary and *valet de chambre* to the king, made the cartoons used by Nicolas Bataille (*tapissier de Paris*) in weaving two hangings representing the Apocalypse (1377).

[2] "*Tapis de haute lice de fin fil d'arras ouvré à or de Chipre*" (A.D. 1395). One of the largest and most delicately wrought tapestry hangings in which gold and silver threads are freely used is that of the Adoration of the Eternal Father: on the left of this is the story of the Emperor Augustus and the Tiburtine Sibyl: on the right the story of Esther and Ahasuerus. It was bought by Mr Pierpont Morgan.

[3] Only one or two of the tapestries representing the several engagements between the English and Spanish fleets in 1588 which used to hang in the House of Lords (see Pine, *Tapestry of the House of Lords*, London, 1739) were saved from the fire (1835), and are now at Hampton Court. They closely correspond with a set commemorating engagements between the Dutch and Spanish fleets (1572 and 1576) which are in the great Assembly Hall of the Provincial States of Zeeland. These latter were woven chiefly at the tapestry works at Middelburg, 1595–1629; the former were woven at Francis Spiring's works (or Spierincx) at Delft. Both, it appears, were designed by H. Cornelius Vroom of Harlem. For interesting details of the Middelburg works see van der Graft's *De Tapijt-Fabrieken* (Middelburg, 1869), and supplementary documents by De Waard (Oud-Holland, xv., 65, 1897).

[4] See lists in W. G. Thomson's *History of Tapestry*.

[5] Rot. Pat. 38 Ed. III., Hardy's *Record Rymer*, vol. 3, part 2, p. 736.

compositions, and the flowers, &c., as in the ground of Fig. 18, and might complete or correct their cartoons with charcoal or chalk, but for every other style of work they were bound to apply to professional painters under pain of fine.[1]

In 1528 the Brussels *tapissiers* and dealers in tapestries were required to mark their weavings, and Charles V. ordered all tapestry makers in the Low Countries to do the same.[2] This practice was followed in other countries into which emigrant Flemish or French weavers had carried the industry, making their tapestries very often from copies they took with them of cartoons designed by noted Italian and Flemish painters. Makers' marks have in so many cases been cut from tapestries that it becomes practically impossible to identify the places where they were made, and the dates of their production can only be conjectured from the styles of designs, supplied for instance by such artists (or their followers) as the Van Eycks, Roger van der Weyden, Mantegna, Leonardo da Vinci, Raphael, Bernard van Orley, Lancelot Blondeel and John van der Straaten or Stradanus; this last-named was for many years employed in connexion with the important "Arrazeria Medici" founded in Florence by Cosmo I., duke of Tuscany (1537), which lasted until the beginning of the 18th century; Stradanus's style of design is similar to that of episodes in the story of Dido and Aeneas shown in fig. 23 from an Oudenarde tapestry of the early 17th century. Reverting to the 16th century, reference must be made to Cardinal Wolsey and Henry VIII., who possessed enormous quantities of the best Flemish tapestries of their time and earlier, and a fair number of them are still preserved at Hampton Court Palace.[3] The king had in his service not only agents especially in Brussels to buy hangings, but also a considerable staff of "Arras-makers." In Ireland, the taste for tapestry was evidenced by a manufactory at Kilkenny of "tapestry, Turkey carpets and diapers," founded early in the 16th century at the instance of Piers, 8th earl of Ormond and his lady, Margaret FitzGerald, and giving employment to workmen introduced by him from Flanders.[4] At a rather later date tapestry works were established by William Sheldon at Weston and Barcheston in Warwickshire, with a view to which he previously sent Richard Hickes to the Low Countries to learn tapestry-weaving. A few Flemings were probably brought over by him and set to work at Barcheston and Weston, where he was appointed "master weaver." In his will (1569) Sheldon calls Hickes, somewhat erroneously perhaps, "the only auter and beginner of tapestry and Arras within this realm." His son, Francis Hickes, was educated at St Mary Hall, Oxford (1579–83), and about 1640 he caused some tapestry maps to be woven.[5] Made before them are a set of hangings of the "Four Seasons," now preserved at Hatfield. These are most probably from designs by Francis Hickes. They were bought by the marquis of Salisbury very shortly before the first visit of Queen Victoria to Hatfield. The borders of these pieces with small medallions and Latin mottoes are attractively amusing and interesting. In the lower border (fig. 24) one may read "VIA. VIRTUTI. ENCYCLOPEDIA"; in the upper border a date, "1611," occurs in one medallion. In the upper border of each hanging is an important coat of arms with several quarterings, chief of which are those of Tracey of Toddington in Gloucestershire impaling those of Shirley of Wiston in Sussex. The designer's inventiveness and fancy in illustrating attributes, &c., of the "Seasons" are almost exuberant, however restricted and quaint his graphic power seems to be.

Tapestry makers' marks.

Artists who designed cartoons for tapestry.

Philip II. is mentioned as having encouraged a manufacture of tapestry by Flemings in Madrid in 1582. In 1539, Francis I. started a royal factory for tapestry at Fontainebleau (see fig. 20), and employed Primaticcio amongst other artists to furnish the necessary designs. Henry II., whilst continuing work at Fontainebleau, caused a second factory to be set going in Paris at the Hôpital de la Trinité. Henry IV. continued this royal patronage in lavish fashion and added yet another factory, that in the Faubourg St. Antoine, which in 1603 was transferred to workrooms in the Louvre. As Paris thus came to the fore, so Brussels gradually declined. Upon the death of Henry IV. in 1610 Paris tapestry-making suffered a check, which may perhaps have contributed somewhat favourably to the start made by James I. to organize the Mortlake works, where several foreign workmen were employed under the direction of Sir Francis Crane.[6] Both James I. and Charles I. supplied considerable sums of money for the Mortlake works, and tapestries were made there, as fine as any comtemporaneously at Paris or Brussels, *e.g.* those from Raphael's cartoons of "the Acts of the Apostles,"[7] Rubens's "Story of Achilles," and portraits by Van Dyck. After the execution of Charles I., Mortlake declined, and new life was infused into the industry at Paris under the influence of Colbert, to whose strong personal interest in the arts is due the organization in 1667 of the Hôtel des Gobelins under the painter Charles le Brun as the *Manufacture Royale des Meubles de la Couronne*, which for large hangings became the premier tapestry-weaving centre in Europe. Three years previously Colbert had initiated a similar manufactory, chiefly with low-warp frames, at Beauvais, which is noted for sofa and chair seats and backs, screens and small panels.

Efforts to establish the industry in Rome were made during the 17th century, but it is only since the pontificate of Clement XI. in 1702 that a papal factory has been successfully conducted and is still carried on in the Vatican. The manufactory of Santa Barbara in Madrid was founded by Philip V. in 1720, and although it was closed in 1808 it re-opened in 1815 and is still at work.

Tapestry-weaving during the 18th century under private enterprise was pursued with success and still continues at Aubusson, Felletin; it was carried on for a short time only at Fulham, Soho, Exeter, and for rather longer periods at Lille, Cambrai, Gisors, Nancy, Naples, Turin, Venice, Seville, Munich, Berlin, Dresden, Heidelberg and St Petersburg, maintaining, however, no very prolonged existence at any of these latter places. In more modern times English tapestries woven after 1878 at the Merton works from designs by William Morris (see fig. 26), as well as by Sir Edward Burne-Jones[8] and Mr Walter Crane, have great distinction in vigorous style reminiscent of virile medieval work. In mere technique of weaving with fine warp and weft they are outdone by the comparatively effeminate and delicate painting-like fabrics now made at the Gobelins and Aubusson.

18th and 19th century tapestry-weaving.

Towards the end of the 17th century as well as early in the 18th century some tapestry-weaving was carried on in Ireland. For about twenty years at Chapelizod, near Dublin, tapestry frames were worked by Christopher and John Lovett, the latter of whom had to leave Dublin, bringing with him into England some thirty-eight pieces of tapestry of "Their Majesties' Manufacture of Ireland." In the Bank of Ireland, in College Green, Dublin, are two large hangings which were executed by Robert Baillie, who is said to have held the appointment of upholsterer to the Irish government in 1716.[9] One of them represents the Battle of the Boyne, the other the "Glorious Defence of Londonderry" (see fig. 25). Lough Foyle and the hill surmounted by the city of Londonderry are represented in the landscape: to the left in the foreground is James II., by whom is the Commander Hamilton with his hat off, and near at hand cavalry: on the right are mortars, cannon and foot soldiers. The border of this tapestry is fantastic in design and rather in the style of an over-elaborated theatre proscenium, upon which hang medallions containing portraits of Captain Baker, the Rev. Dr Walker and the captain of the frigate "Dartmouth," in which the supplies were brought to the besieged which led to the relief of the city and the defeat of the investing army. The designs for these Dublin tapestries are credited to John Vanbeaver, a Flemish weaver, who seems to have been a moderate draughtsman. They are clearly adaptations of designs of historical events, by Le Brun and van der Meulen, from which tapestries were woven at the Gobelins factory to the order of Louis XIV. at the end of the 17th century. These Dublin hangings were woven about 1735, and Baillie was commissioned to make four others representing the landing of the prince of Orange, his army at Carrickfergus, the Battle of Aughrim, and the taking of Cork and Kinsale by Marlborough.[10] These, however, were not completed, and Baillie was paid £200 as compensation.

Tapestry-weaving as a possible cottage or home industry is practised in a few places in Ireland and England. In the Far East, China and Japan, the art, adopted presumably from western Asia, is sometimes resorted to in making silken robes and intricately figured hangings. The Japanese call their tapestry-weaving *tsu-zu-re-ori.*

FIG. 18.—Brussels, early 16th century, hanging, covered with masses of flowers, on which are shields bearing the royal arms. Now at Haddon Hall. The property of the duke of Rutland.

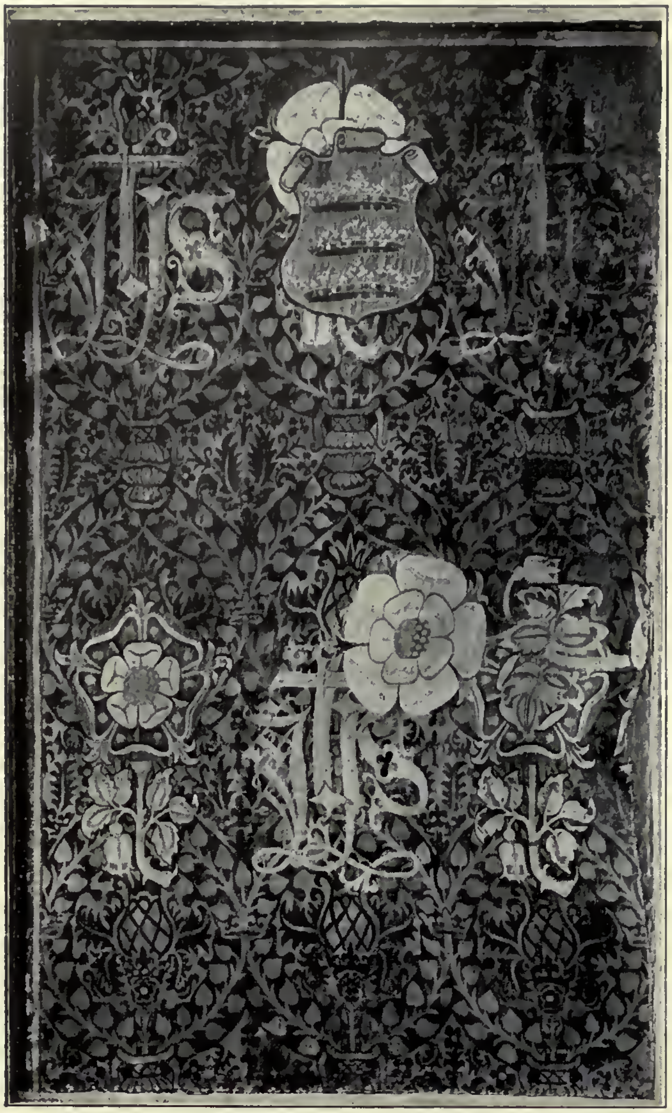

FIG. 19.—Brussels tapestry (about 6 ft. high), late 15th century, with a shield bearing three crowns, red and white roses, and the monogram I.H.S. repeated three times. From Winchester College.

FIG. 20.—Tapestry hanging (about 10 ft. high) possibly of Fontainebleau manufacture about 1540. Fêtes in honour of Henri II. and Catherine de Medicis.

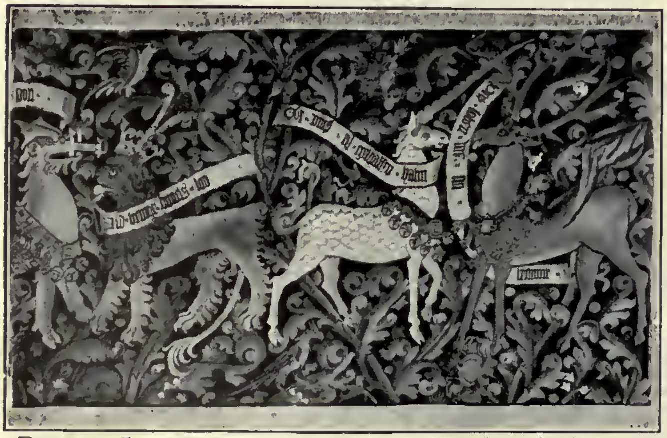

FIG. 21.—German tapestry hanging (about 4 ft. 6 in. long by 3 ft. high) for a sideboard or buffet, middle of the 15th century. In the museum at Basel.

FIG. 22.—Tapestry hanging (about 10 ft. high) made at the Medici factory in Florence, 1639. Domestic scene, *l'Inverno*, winter.

FIG. 23.—Oudenarde tapestry, early 17th century. The design, "Dido and Eneas," rather in the style of J. van Straeten.

FIG. 24.—One of the four tapestry hangings of the "Seasons," of Winter with Aeolus in the centre, probably woven under the direction of Francis Hickes at William Sheldon's manufactory at Barcheston, in Warwickshire, early in the 17th century, and now at Hatfield House.

TAPESTRY

FIG. 25.—Defence of Londonderry. Irish (Dublin) tapestry, early 18th century.

FIG. 25.—Tapestry woven at Merton Abbey, from a design by William Morris (1834–1896). The subject is from his poem "The Orchard." Victoria and Albert Museum.

Fine examples of early and later European tapestries are to be seen in the cathedrals of Reims, Bruges, Tournai, Angers, Beauvais, Aix, Sens, in the Victoria and Albert Museum, London, Windsor Castle, Hampton Court, St Mary's Hall Coventry, the Louvre and Cluny Museums in Paris, at Chantilly, Chartres, Amiens, Dijon, Orleans, Auxerre, Nancy, Bern, Brussels, Basel, Munich, Berlin, Dresden, Vienna and Nuremberg. In Italy the largest collections (mostly of 16th and 17th century work) are those of the Vatican at Rome, and the *Reale Galleria degli Arazzi* at Florence. Many fine pieces are in the royal palace at Turin, the *Palazzo del Tè* at Mantua, the royal palace at Milan, in the cathedral of Como, and the museum at Naples. The collection at the palace of Madrid is one of the largest in Europe, and comprises more than one thousand examples, the older of which, of splendid Flemish design and weaving, belonged to Ferdinand and Isabella, Philippe le Bel and the Emperor Charles V.[1] The principal cathedrals of Spain also possess important tapestries; those preserved at the cathedral of Toledo are more than enough to supply hangings for the outside and inside of that building on the feast of Corpus Christi. Throughout the European continent, in the United States of America, and in Great Britain almost uncountable tapestries are displayed or stored in mansions, castles, *châteaux* and *palazzi*, belonging to noble and wealthy families. A large number of books have been written and published on the subject generally, and many of them, containing good illustrations, are of recent date.

Places where fine tapestries are now preserved.

BIBLIOGRAPHY.—The following works may be mentioned as likely to prove useful for investigating the history and character of Egypto-Roman and Coptic textiles:—J. Karabacek, *Die Theodor Graf'schen Fünde in Aegypten* ("*Die Textilien-Gräberfünde*"), 8vo, Vienna, 1883; Alan S. Cole, *Catalogue of a Collection of Tapestry Woven and Embroidered Egyptian Textiles in the South Kensington Museum*, London, 1887; "Egyptian Tapestry," Society of Arts, Cantor Lectures, London, 1889; A. Riegl, *Die ägyptischen Textilfünde im K. K. Österreich. Museum*, 13 photo-lithographs, 4to, Vienna, 1889; E. Gerspach, *Les tapisseries coptes*, 153 (some coloured) illustrations, 4to, Paris, 1890; R. Forrer, *Mein Besuch in El-Achmim*, 1 phototype and 36 process illustrations, 8vo, Strassburg, 1895; *Römische und Byzantinische Seiden-Textilien aus dem Gräberfelde von Achmim-Panopolis*, 28 pp., 17 (15 coloured) plates, and illustrations in the text, 4to, Strassburg, 1891; Wladimar Bock, *Coptic Art; Coptic Figured Textiles* (in Russian), 32 pp., 6 phototype plates, 4to, Moscow, 1897; W. Lowrie, *Christian Art and Archaeology* (pp. 362–82, "Textile Art"), process illustrations, 8vo, New York and London, 1901; A. Gayet, *L'art copte* (pp. 317–27, "*Les tissus*"), process illustrations, 8vo. Paris, 1902.

In respect of medieval and later tapestries the titles of the following works are quoted:—Jubinal, *Anciennes tapisseries*, Paris, 1838–39; Ronchaud, *La tapisserie dans l'antiquité; Le péplos d'Anthéné*, Paris, 1884; Müntz, *La tapisserie*, Paris, 1882; Boileau, *Les métiers et corporations de la ville de Paris au xiii^e siècle*, Paris, 1879; Barbier de Montault, *Tapisseries du sacre d'Angers*, Paris, 1863; De Farcy on the same subject, 1875; Barraud, *Tap. de la cath. de Beauvais*, Beauvais, 1853; Pinchart, *Roger van der Weyden . . . et les tapisseries de Berne*, Brussels, 1864; Loriquet, *Tap. de la cathédrale de Reims*, Reims, 1882; Guiffrey, Pinchart and Müntz, *Histoire générale de la tapisserie*, 1878; Müntz, *Les fabriques de tapisseries de Nancy*, 1883; Voisin, *Tap. de la cath. de Tournay*, Tournai, 1863; Van Drival, *Tap. d'Arras*, Arras, 1864; Gorse, *Tap. du château de Pau*, Paris, 1881; De la Fons-Melicoq, *Hautlisseurs des xiv^me au xvi^me siècles*, Paris, 1870; *Notice sur les Tap. de Beauvais*, Clermont, 1842; Deville, *Statuts, etc., relatifs à la corp. des tap. de 1258 à 1275*, Paris, 1875; Darcel, *Les manufactures nationales de tapisserie des Gobelins de Paris*, 1885; van de Graft, *De Tapijt-Fabrieken der xvi. en xvii. Eeuw*, Middelburg, 1869; De Montault, *Tap. de haute lisse à Rome*, Arras, 1879; Conti, *L'arte degli arazzi in Firenze*, Florence, 1875; Campori, *L'arazzeria Estense*, Modena, 1876; Braghirolli, *Arazzi in Mantova*, Mantua, 1879; Farabulini, *L'arte degli arazzi*, Rome, 1884; Gentili, *L'art des tapis*, Rome, 1878; Müntz, *Tap. TAPEWORMS. The Cestodes or Tapeworms form a class of purely endoparasitic Platyelmia, characterized by their elongate shape, segmented bodies, and the absence of a digestive system. With few exceptions they are composed (1) of a minute organ of fixation (the scolex), which marks the proximal attached end of the body; (2) of a narrow neck from which (3) a number of segments varying from three to several thousands are budded off distally. These segments, or "proglottides," become detached in groups, and if kept moist retain their powers of movement and vitality for a considerable time. This fact gave rise in ancient times to the false idea that the tapeworm originated from the union of these segments; and in modern times it has led to the view that the tapeworm is not a segmented organism (the monozoic view), but is a colony composed of the scolex which arises from the embryo and of the proglottides, which are asexually produced buds that, upon or before attaining their full size and maturity, become separated, grow, and, in some cases, live freely for a time, just as the segments of a strobilating jelly-fish grow, separate and become sexual individuals (the polyzoic view). Whether this view is soundly based is discussed below; the fact remains, however, that a tapeworm is, with few and rare exceptions, not directly comparable at all points with a liver-fluke or indeed with any other organism. The influence of parasitism has so profoundly influenced its structure that its affinities are obscured by the development of specialized and adaptive features.

In contrast to these segmented or "merozoic" Cestodes, a few primitive forms have preserved a unisegmental character and form the Monozoa or Cestodaria. We may therefore divide Cestodes into the Monozoa and the Merozoa.

Order I.—MONOZOA

This order comprises a few heterogeneous forms which probably constitute at least three families.

Family I. *Amphilinidae.*—Oval or leaf-shaped animals found in the sturgeon and certain other fish.

Amphilina foliacea (fig. 1) is in many ways closely allied to the Trematoda, from which, however, it is distinguished by the want of a digestive system. One end of the body (usually designated anterior) is provided with a glandular pit (fig. 1, A*a*) which is regarded as a sucker or as related to the uterine opening (birth-pore). The excretory system consists of peculiar cells, each of which bears several "flames" or bunches of synchronously vibrating cilia. These cells are imbedded in the peripheral parenchyma, and lead into convoluted excretory tubes that form an anastomosis opening to the exterior by a pore at the "hinder" end of the body. The epidermis consists of pyriform cells, which send richly branched processes to the superficial cuticle. The parenchyma is made up of stellate cells the processes of which form a reticulum. The reproductive organs consist of the parts shown in fig. 1, A, and it will be seen that, in addition to the openings of the male

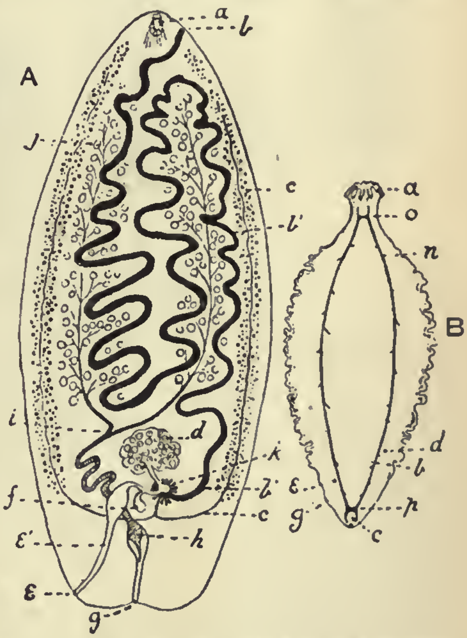

FIG. 1.—A, reproductive system of *Amphilina foliacea*: *a*, glandular pit; *b*, opening of uterus; *b'*, uterus (black); *c*, yolk-gland and its duct; *d*, ovary; *e*, *e'*, opening and duct of vagina; *f*, spermotheca; *g*, male genital opening (gonopore); *h*, penis; *i*, vas deferens; *j*, testes; *k*, shell-gland. B, *Amphiptyches* (*Gyrocotyle*) *urna*. Outline of the ventral surface to show the external apertures and nervous system; *a*, rosette-organ; *b*, uterine pore; *c*, terminal sucker; *e*, vaginal pore; *g*, male gonopore; *n*, *o*, *p*, nervous system. (From Lankester's *Treatise on Zoology*, part iv.)

and of the female (vaginal) ducts, there is a distinct uterine opening at the opposite end of the body (*b*). Moreover, in *Amphilina liguloidea* a fourth duct (the anterior vagina) begins close to the origin of the female duct, and after running forward a short distance ends blindly (see fig. 7, C). The egg gives rise to an oval larva, one half of which is ciliated and bears gland-cells, the opposite end carrying ten hooks. The fate of the larva is unknown.

Family II. *Gyrocotylidae.*—Leaf-shaped animals with crenate margins. One extremity carries a pedunculate rosette-organ. It is traversed by a canal from which a peculiar proboscis-like structure can be exserted. The opposite end is pointed and provided with a terminal sucker. *Amphiptyches* (=*Gyrocotyle*) *urna* (fig. 1, B) is found in the intestine of *Chimaera* and *Callorhynchus*, and has been almost fully described by Spencer (7). The embryo is provided with ten hooks, and appears to select Lamellibranchs (*Mactra*) for its intermediate host.

Family III. *Caryophyllaeidae.*—Elongated cylindrical animals either with a single subterminal sucker at the proximal end, or with the corresponding end of the body converted into a mobile undulatory fold. *Caryophyllaeus mutabilis* occurs in the roach and other fresh-water fish, and passes its earlier stages of development in fresh-water Oligochaets (*Tubifex*). *Archigetes appendiculatus* lives throughout life in the coelom of *Tubifex* and of *Limnodrilus.*

Archigetes and *Caryophyllaeus* are the only Cestodes that become fully differentiated in an invertebrate host. The former indeed

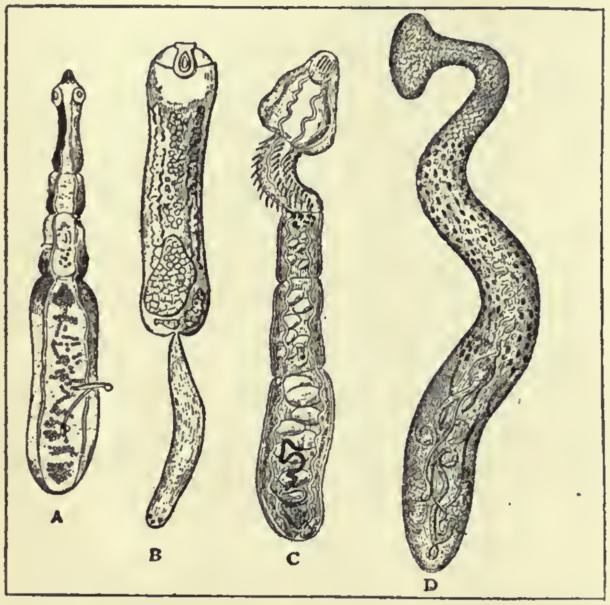

FIG. 2.— Various Forms of Tapeworms. A, *Taenia echinococcus*; × 12 (from Leuckart). B, *Archigetes sieboldi;* × 60 (from Leuckart). C, *Echinobothrium typus;* × 10 (from Van Beneden). D, *Caryophyllaeus mutabilis;* × about 5 (from Carus).

is said to produce fully developed gonads, and if kept in aquaria with *Tubifex*, the number of infected worms steadily increases, a fact pointing to the whole cycle being passed through, without the intermediation of a vertebrate host. Conclusive evidence, however, has not yet been adduced to prove this point. The two genera agree closely in form and structure and may possibly belong to the cycle of the same or of allied species. *Archigetes* (3 mm. long) consists of a subcylindrical body and a caudal appendage. The former bears two terminal suckers on the flattened dorsal and ventral surfaces, the latter six hooks near the tip of the tail. The finer structure of the animal has been investigated by Mrazek (10), whose account, however, is published in the Hungarian language. It shows a close agreement with that of *Caryophyllaeus.* A well-developed cellular parenchyma forms a matrix in which the muscular, excretory and generative organs are imbedded. The nervous system consists of a ring below the suckers and of a large number of radially arranged tracts running forwards and backwards. *Caryophyllaeus* is an elongated, flattened worm provided with one extremely mobile extremity, the other being drawn out during the animal's sojourn in *Tubifex* into a short hexacanth tail. It becomes fully developed in its invertebrate host, but apparently cannot produce eggs until transferred into the intestine of a fish.

Order II.—MEROZOA

The Merozoa, to which the ordinary tapeworms of man and domestic animals belong, includes the great majority of the Cestodes. They occur in vertebrate animals throughout the globe, though varying in abundance in different districts and at different times. With few exceptions tapeworms select the small intestine for their station, and in this situation execute active movements of extension and contraction. The body, or "strobila," consists of a usually minute organ of attachment (scolex or its representative) which is imbedded in the intestinal membrane, and of a series of segments that arise from the base of the scolex and increase in size distally. In one family (*Ligulidae*) the segmentation is only expressed in the metameric distribution of the generative organs and the worm is externally unisegmental. In the remainder the segmentation involves primarily the genitalia and includes the integument, muscles and part of the excretory system. The nervous system is, however, not segmented, and the excretory system is continuous throughout the worm.

Scolex.—The scolex is biradially constructed, the proglottides flattened, quadrangular and bilaterally symmetrical. In them a ventral surface containing the usually median male and female genital apertures is generally distinguishable from the smooth

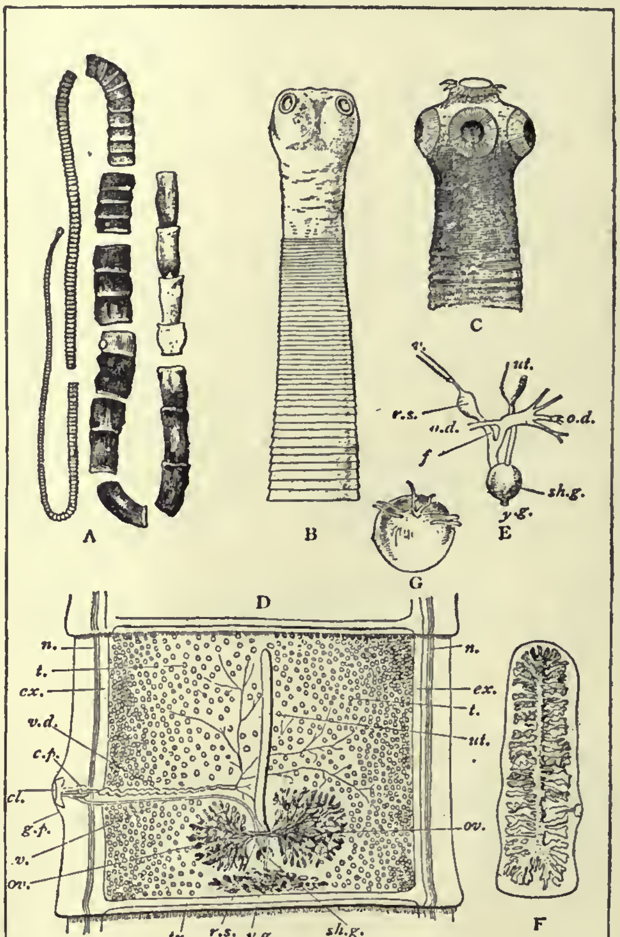

FIG. 3.—Anatomy of *Taenia* (from Leuckart). A, portions of *Taenia saginata*; × ½. B, head of the same; × 8. C. head of *T. solium*, showing the crown of hooks; × 22. D, a segment of *T. saginata*, showing the generative organs: *n.*, nervous system; *ex.*, longitudinal excretory tubes; *tr.*, transverse vessel; *g.p.*, genital papilla; *cl.*, cloaca; *c.p.*, cirrus pouch; *v.d.*, vas deferens; *t.t.*, testes; *v.*, vagina; *ov. ov.*, ovaries; *sh.g.*, shell gland; *y.g.*, yolk gland; *r.s.*, receptaculum seminis; *ut.*, uterus; × 7. E., the connexions of the generative organs, lettering as above: *o.d.*, *o.d.*, oviducts; *f.*, fertilizing canal; × 30. F, detached segment of *T. saginata*, showing ripe uterus; × 2. G, six-hooked embryo, highly magnified.

dorsal surface, but in those Cestodes which possess marginal gonopores this distinction of surface is obscured. In such cases the male organs are regarded as indicating the dorsal surface, the female organs as belonging to the ventral surface.

The scolex is usually a conical muscular structure. It bears adhesive organs that are either suckers or hooks, and may develop into the most varied outgrowths in order to give increased firmness of attachment to its host. Thus, starting from the two shallow pits, one dorsal and the other central, in the simplest forms, we find them becoming two elongated suckers (bothria) in the large family *Bothriocephalidae* (fig. 8); and by fusion of the lips they are transferred into two tubes (*Solenophoridae*); and by the closure of the lower aperture reconstituted into two suckers, the margins of which are produced and folded so as to resemble the leaf-like outgrowths of the next group. In this division (Tetraphyllidea) four suckers or bothria are developed on the scolex, but their cavities are extremely shallow and their lips extremely mobile and variable in shape. Hence they are called phyllidia (fig. 4). These organs may be raised on a short stalk, their cavity subdivided into loculi, and provided in some cases with hooks. A peculiar modification of this type of scolex occurs in the *Echinobothridae*, in which the axial part of the organ (the rostellum) is elongated and provided with several rows of hooks, whilst the phyllidia have partially fused. This elaborate type of scolex appears to be an adaptation to grasp the spiral intestinal valve of sharks and rays. But perhaps the most elaborate scolex is that of the Tetrarhyncha (fig. 5), which are also parasitic in Selachians. The four suckers are here united to form two pairs or fused into a single pair. Internal to the suckers are the four complex hooked proboscides. Each consists of an eversible hollow tentacle provided with hooklets and capable of introversion within a membranous sheath filled with fluid. The sheath terminates in an elongated muscular bulb. The muscles are arranged in ten or more layers, and are transversely striated. These complex organs have apparently arisen by the increase in depth and differentiation of an accessory sucker such as is borne on the phyllidia of the former group. Lastly, the scolex of the more familiar *Taeniidae* (Tetracotylea) carries a rostellum encircled with hooks and four cup-shaped suckers the margins of which do not project beyond the surface of the body. It seems probable that these suckers are not the true "bothria" but are developed from accessory suckers, the bases of which have disappeared almost completely. In one genus (*Polypocephalus*) the place of a rostellum is taken by a crown of retractile tentacles. This order is almost exclusively parasitic in warm-blooded animals.

FIG. 4.—Scolex of *Calyptobothrium riggii* from the Torpedo, magnified to show the four "phyllidia," each of which has a sucker. (From Braun, in Bronn's *Klassen u. Ordnungen d. Thierreichs*, by permission of C.S. Winter'sche Verlagshandlung).

The extraordinary variety of form and complication of structure exhibited by the appendages of the scolex are adaptations to fix the worm and to resist the peristaltic action of the intestine in which it lives, and are not connected directly with the absorption of food.

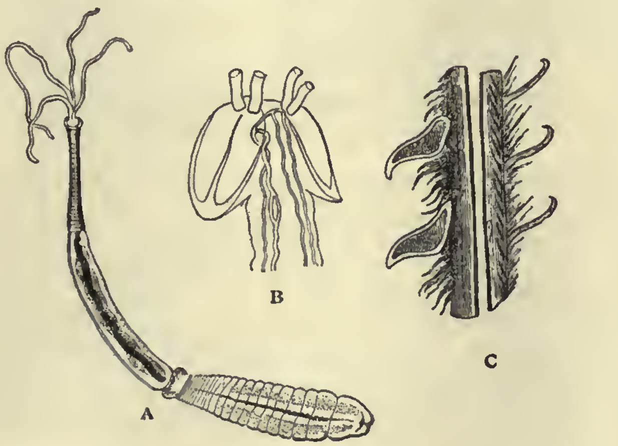

FIG. 5.—*Tetrarhynchus*. A, general view of the worm; × 4. B, head showing the suckers, proboscides and excretory canals; × 25. C, portion of a proboscis showing the two forms of hooks; highly magnified. (All from Pintner.)

Proglottides.—The segments into which the body is divided vary considerably in number, size and form. *Taenia echinococcus* has only three, *Echinobothrium* four, *Bothriocephalus* three thousand. In every species the segments develop from the scolex distally and increase in size with the maturation of the contained female genital organs. When this is reached, growth of the proglottides ceases. As a general rule the ripe proglottides are detached in chains and replaced by others which in their turn become detached, the process being repeated for a year or so until the worm weakens and is cast out. In special cases, however, a proglottis may be detached before attaining full growth, and with its generative organs in an imperfectly developed condition. The minute *Taenia* (*Davainea*) *proglottina* (·5 to 1 mm. in length) from the common fowl detaches its four or five segments into the intestine, where they attain a length of 2 mm., and a breadth of 1·25; that is, more than twice the size of the parent. The Cestodes of Elasmobranch fish offer more convincing examples of independent growth of the proglottides, for these are often set free with only the male organs developed, and each attains twice the size of the parental strobila.

The form of the proglottides is most generally a rhombic or trapezoidal figure. The hinder border is often drawn out into mobile processes and hollowed out around the insertion of the next segment. At this neck-like zone the muscles are absent, and across it falls the line of fracture when the proglottis separates from its fellows.

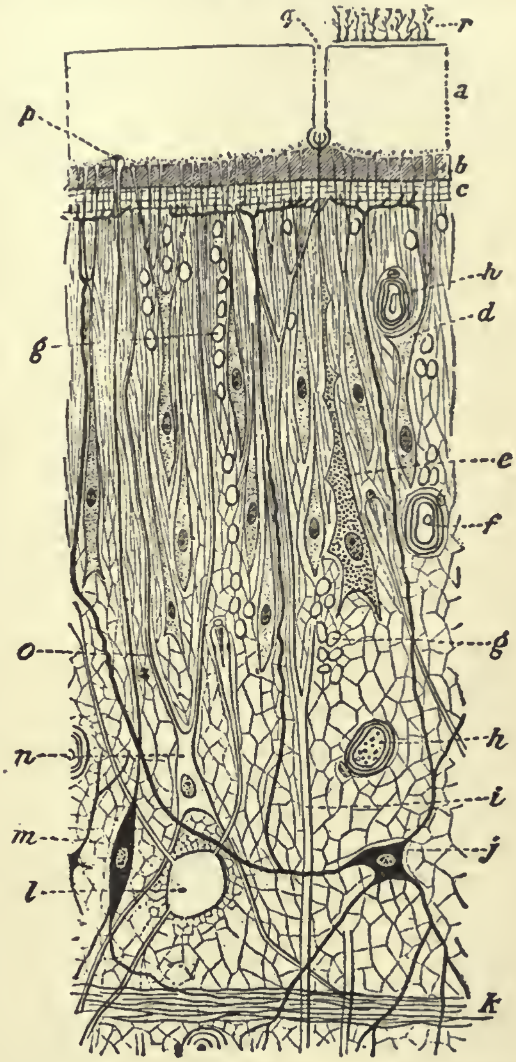

FIG. 6.—Diagram of a transverse section through the body-wall of a young *Ligula*, illustrating the microscopic structure of tapeworms. *a*. cuticle; *b*, basal membrane; *c*, outer circular muscles; *d*, epidermal cells depressed below the surface usually occupied by them in other animals; *e*, gland cell; *f*, "flame-cell" (the reference line stops a little short); *g*, outer longitudinal muscles; *h*, a calcareous corpuscle; *i*, dorso-ventral muscles; *j*, a "parenchyma" cell (probably nervous); *k*, nerve-plexus; *l*, excretory vessel giving off capillaries ending in flame-cells; *m*, a sense-cell; *n*, a muscle-cell; *o*, ending of the same; *p*, ending of sense-cell; *q*, opening of gland-cell; *r*, superficial cuticle. (From Lankester's *Treatise on Zoology*, part iv.)

Structure.—The anatomy of the Cestoda differs in only two or three important features from that of Trematodes. In both classes the body is encased by a thick non-cellular cuticle, the deepest layer of which—the subcuticle or basal membrane (fig. 6 *b*)—is perforated by the branched free ends of the isolated epidermal cells, which have sunk into the body, and by the endings of gland-cells and nerve-cells (fig. 6). The mass of the body consists of richly branched stellate cells—the mesenchyma—and imbedded in this plasmic tissue are the nervous, excretory, muscular and generative organs.

The excretory organs consist of flame-cells, richly convoluted canaliculi, and a pair of longitudinal canals leading to the exterior by one or more pores. The muscles are composed of outer circular and inner longitudinal layers, and of branched dorso-ventral fibres. The generative organs are of the complex hermaphroditic type described in Trematoda (*q.v.*). In these broad anatomical features both classes agree. But whilst in Trematoda a digestive sac is invariably present except in the sporocyst larval stage, the Cestodes possess no trace of this organ at any stage of their development. They obtain food entirely by osmosis through the striated cuticle, and this food consists not of blood, as in flukes, but of chyle, by which they are bathed in their favourite site, the small intestine.

The second point of difference between tapeworms and Trematodes lies in the absence of a definitely demonstrable "brain." The concentration of nervous matter and ganglionic substance at the oral end of Trematodes is equivalent to the "brain" of the Planarians, but the similar thickening in the scolex of Cestodes is by no means so certainly to be called by that name. It appears to be primarily related to the organs of attachment and to have attained greater elaboration than the rest of the nervous system because the proximal end is the most specialized and most stimulated portion of the worm. Those Cestodes which possess no very distinct organ of attachment (such, for example, as *Gyrocotyle*) have no distinct ganglionic thickening more pronounced at one end of the body than at the other; and as these are forms which have retained more primitive features than the rest, and show closer affinity to the Trematodes, it seems highly probable that the complicated nervous thickening found in the scolex, and often compared with the "brain" of other Platyelmia, is a structure *sui generis* developed within the limits of the sub-class. In the opinion of several zoologists it marks the tail-end and not the head-end of the worm.

The third important contrast in structural features has also been acquired by the Cestoda Merozoa, namely, the repetition of certain organs in a metameric fashion. The Monozoa are unsegmented; the *Ligulidæ* have segmented gonads and gonopores without any trace of somatic metamerization except secondary excretory pores in addition to the usual terminal one; the remaining Cestodes are unisegmental only in their larval stage, and all of them show in their later stages repetition of the reproductive organs and of the musculature. In addition, some show duplication of the gonads and of their ducts, so that we find both transverse and longitudinal repetition of these organs, without corresponding multiplication of the nervous ganglia mesenchyma, or excretory opening.

The last structural peculiarity of the group is the absence of the functions of regulation and reparation which are so highly developed in the more primitive Planarians. This statement is quite consistent with the continuous production of new segments at the neck of the scolex, for such a process is analogous to the development of the segments in a Chaetopod, which is a perfectly distinct phenomenon from the regeneration of new segments to supply the place of a head or tail-end or some other portion that has been lesioned. The replacement of detached mature proglottides at the distal end of the Cestode-body by others is not regeneration, for the replacing set has already developed, and in certain cases they can complete their development quite independently after being detached from the parent. More convincing evidence of the absence of true regeneration, however, is the argument from malformation and the phenomenon known as "pseudo-scolex." It has long been known that proglottides of the same species often exhibit sporadic malformation from the normal shape, and the evidence goes to show that the variation was due to arrested growth or some unusual stress or pressure which, acting upon the young strobila, produced a deformation, and that the proglottides so affected could not regain their normal form. The power of reparation, so conspicuous a feature of Turbellarians, is slight or absent in Cestodes. Moreover, injury to the scolex, or amputation of that organ, reveals the concomitant absence of a regulative mechanism such as that which generally controls the form and fitness of regenerated organs. In such an event, a Cestode cannot replace the injured or severed portion. The first two or three proglottides merely become deformed and produce an appearance known as the pseudo-scolex. The absence of these functions of regeneration and of regulation affords, therefore, corroborative evidence of the highly specialized nature of the Cestode organization.

Reproduction.—The reproductive organs are usually repeated in each proglottis, and in some families two complete sets of such organs occur in each segment; in a few cases, parts only of the system are duplicated. The structure of these organs is seen in figs. 3, 6 and 7, and, as we have said, agrees closely with that of Trematodes. The chief difference between the reproductive organs of the two classes is the presence in Cestodes of a separate vagina and uterus, each of which opens in some families to the exterior by an independent pore. The vagina of Cestodes is undoubtedly comparable with the so-called "uterus" of Trematodes, but the nature of the Cestode uterus is not so clear. It has been compared with the canal of Laurer of Trematodes (the vitello-intestinal duct of the ectoparasitic flukes), but if we take the more primitive Cestodes, and especially *Amphilina*, into consideration we find that they possess, in addition to the uterus, an anterior vagina (usually present in Cestodes) and a posterior one. This last tube is probably the homologue of Laurer's canal (Goto, 8). The single anterior vagina is then comparable with the similarly named duct of ectoparasitic Trematodes, in which group it is either single or double. The accompanying figure will assist this description.

Life-histories.—The life-history of Cestodes consists of larval and adult stages, which are usually passed through in different hosts. The egg gives rise in the uterus to a six-hooked embryo, which reaches the first host in a variety of ways. It may hatch out as a ciliated organism (fig. 8, D) capable of living freely in water for at least a week (*Bothriocephalus*), which then, if eaten by a stickleback, throws off its ciliated envelope, and creeps by the aid of the hooks through the intestinal wall into the body-cavity of the fish. Here it develops into a larval, or rather an adolescent form. In other cases the infection of the first host is brought about by the ingestion

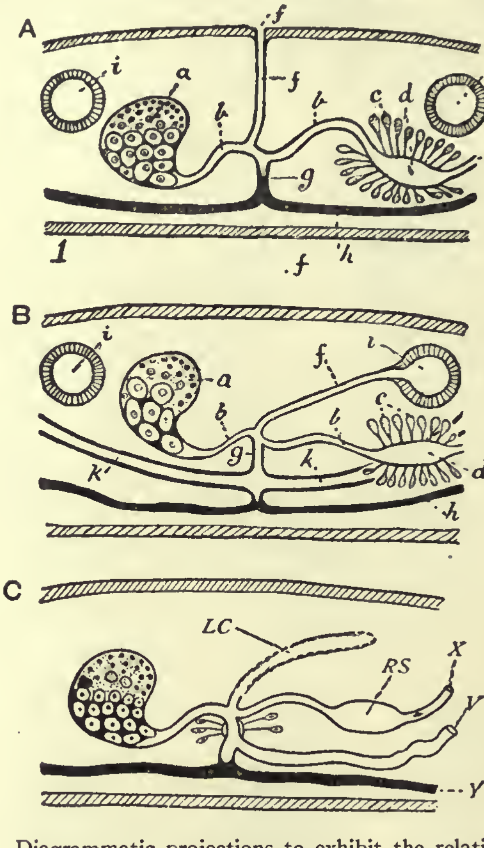

FIG. 7.—Diagrammatic projections to exhibit the relations of the female genital ducts in Trematodes with those in Cestodes. A, in endoparasitic Trematodes (Malacotylea). B, in ectoparasitic Trematodes (Heterocotylea). C, in Cestoda. (The ovary (*a*) leads into (*bb*) the oviduct, which is joined at (*g*) by the duct of the yolk-glands (*h*, *h*, *Y*). In B it is also joined by a paired vagina *k*, *k*, and by the "vitello-intestinal duct" (Laurer's canal, *f*). In the Cestodes the vagina is present (*V*); the canal of Laurer (*LC*) is now vestigial (present in *Caryophyllaeus* as the posterior vagina). The uterus (*X* in figure C) begins in all cases at the shell gland (*c*, *d*) and may exhibit a swelling (*R S*) for the retention of the spermatozoa. *ii* are sections of the intestine. (A and B from Lankester's *Treatise on Zoology*, part iv., C original.)

of proglottides or of eggs which are disseminated along with the faeces of the final host and subsequently eaten by herbivorous or omnivorous mammals, insects, worms, molluscs or fish. Man himself, as well as other mammals, is the intermediate host of the dangerous parasite, *Taenia echinococcus*, in countries where cleanliness is neglected; the pig is the host of *Taenia solium*, and other cases may be seen from the table at the end of this article. The transition of the larva from the intermediate to the final host is accomplished by the habits of carnivorous animals. The Elasmobranchs swallow infected molluscs or fish; pike and trout devour smaller fry; birds pick up sticklebacks, insects and worms which contain Cestode larvae; and man lays himself open to infection by eating the uncooked or partially prepared flesh of many animals.

The peculiar feature of the larval history of Cestodes is the development in most cases of a cyst or hydatid on the inner wall of which the scolex is formed by invagination. The cyst is filled with a toxic fluid and may bud off new or daughter scolices. In this way bladders as large as an orange and containing secondary bladders, each with a scolex, may arise from a single embryo. We have, in fact, a form of larval multiplication that recalls the development of digenetic Trematodes.

The eggs of Cestodes consist of oval or spherical shells ($\frac{1}{500}$ in.

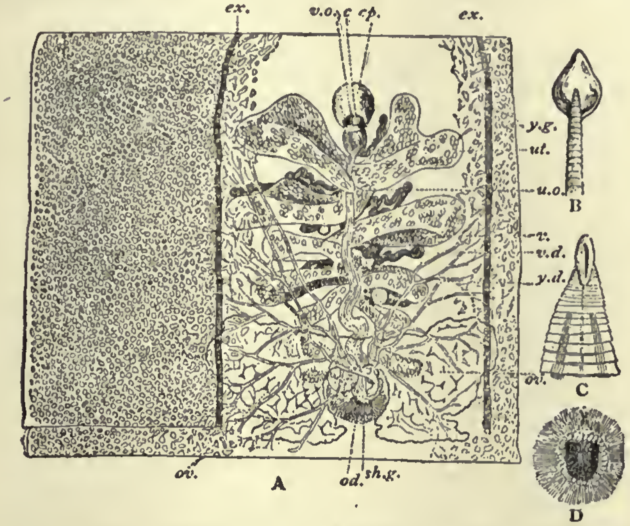

FIG. 8.—*Bothriocephalidae.* A, a segment of *Bothriocephalus latus*, showing the generative organs from the ventral surface; *ex.*, excretory vessels; *c.*, cirrus; *c.p.*, cirrus pouch; *v.d.*, vas deferens; *v.o.*, vaginal opening; *v.*, vagina; *sh.g.*, shell-gland; *od.*, oviduct; *ov.*, ovary; *y.g.*, yolk-gland; *y.d.*, its duct; *ut.*, uterus; *u.o.*, uterine opening; the testes are not visible from this side; × 23 (from Sommer and Landois). sphere" takes place in the uterus. The ovum first divides into (*a*) a granular cell, and (*b*) a cell full of refringent spherules. The former divides into (*c*) small cells or micromeres, and (*d*) large cells or megameres. (*c*) forms the body of the embryo, (*b*) and (*d*) enclose it and form a covering. The embryo undergoes differentiation into an outer layer of cells that produce a chitinoid coat, a middle layer of cells, and a central spherical hexacanth body closely enveloped by the middle coat. In a few genera the place of the chitinoid coat is taken by a ciliary investment and in most families the structure of the layers is characteristic.

Arrived in the intestine of the intermediate host, the hooked embryo is set free and works its way to some distant site. Here it undergoes a change into a cystic or "metacestode" state. A cavity appears in its centre and it acquires a pyriform shape. The thicker portion develops a terminal muscular rostellum and two or four suckers, the thinner end ("tail") is vesicular, more or less elongated, and contains the six embryonic hooks. By a process of infolding, the thicker end is partially invaginated, the middle portion or "hind-body" and the organism may now present a superficial likeness to a cercaria. An excretory system develops, opening at

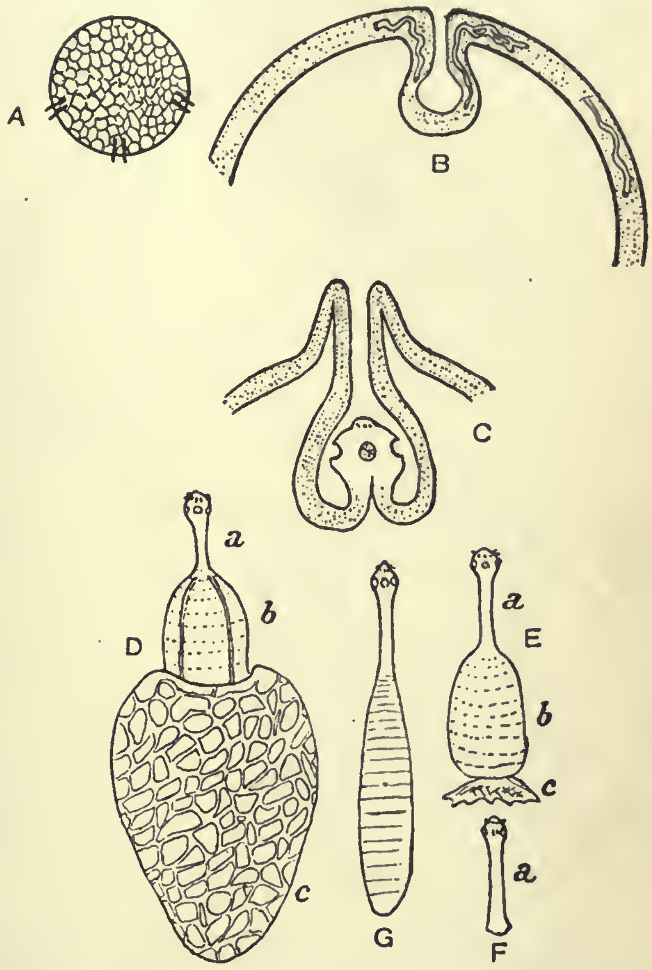

FIG. 10.—The development of a Cestode from a cysticercus (bladder-worm or hydatid). A, the six-hooked embryo. B, portion of the bladder (hind-body and tail), showing the invaginated portion (scolex) and traces of the excretory system. C, further stage in the development of the scolex. D, the entire bladder-worm with scolex everted (drawn from *Cysticercus pisiformis*, common in the rabbit): *a*, scolex; *b*, fore-body; *c*, hind-body and tail. E, F, result of digestion of cysticercus in the stomach of the dog. G shows formation of proglottides. (From Lankester's *Treatise on Zoology*, part iv.)

the base of the tail; nervous and muscular systems arise; and finally the rostellum and suckers become completely enclosed in the sac formed by the lateral extension of the "hind-body." When swallowed by the final host such a "*cysticercoid*" larva evaginates its scolex, throws off its hooked vesicular tail, and begins to bud off proglottides at its free end (fig. 10).

Such is the general history of Cestodes whose intermediate host is an Invertebrate. In most other cases the tail is not distinguishable, and the body of the larva is separable only into a scolex invaginated with a bladder (=hind-body and tail). This form of larva is known as a *cysticercus*. In some genera a "urocyst" is formed, the tail of which gives rise to a new cyst and a fresh scolex.

The most remarkable feature of this cystic development is the formation in many genera of several internal buds within a common cyst, each of which forms an independent inverted scolex (*Coenurus*, *Polycercus*); or these internal vesicles may bud off a large number of scolices on their external surface (*Staphylocystis*).

Morphology of the Cestodes.—With regard to the vexed questions of the morphological nature and of the affinities of the Cestodes, divergent views are still held. One view, the monozoic, regards the whole development as a prolonged metamorphosis; another, the polyzoic view, considers that not only is the Cestode a colony, the proglottides being produced asexually, but that the scolex which buds off these individuals is itself a bud produced by the spherical embryo or onchosphere. On this view, therefore, at least two asexual generations (embryo and scolex) alternate with a sexual one (proglottides); and in the case of *Staphylocystis* the cyst contains two asexually produced generations, so that in such forms three stages (embryo, primary scolex-buds, secondary scolices) intervene between the proglottis of a Cestode and that of its offspring. The polyzoic view is ably championed by Braun (2) and (3).

The more valuable point of view is undoubtedly the monozoic one. In accordance with this we can regard the development as an adaptive one and the scolex as invaginated for protective purposes inside the cyst, which is itself an organ comparable to an amnion. On this view, multiple scolices are, therefore, not buds, but an example of the unlocalized organization of the embryo such as occurs in other groups of animals, and is demonstrated by experiment. The evolution of the cysticercoid, cysticercus and other forms of larvae is a varied adaptive phenomenon. With regard to the adult worm we have to remember that its two extremities, scolex and terminal proglottis, are different from the intervening region. The terminal or first-formed proglottis is sterile, and contains the primitive and (except in a few genera) the only excretory pore. The excretory tubes, the nervous system, and the parenchyma and integument are continuous from one end of the worm to the other. The repetition of the genitalia is the real mark of the Cestodes, and we can trace the independence of the somatic from the gonidial metamerism in such forms as *Triaenophorus* and others. In fact, the whole history of the Platyelmia is marked by a great specialization of the reproductive evolutionary history, accompanied by a simple somatic line of evolution. We therefore regard the body of a Cestode as a single organism within which the gonads have become segmented, and the segmentation of the body as a secondary phenomenon associated with diffuse osmotic feeding in the narrow intestinal canal. The origin of the repetition of the gonads has yet to be investigated.

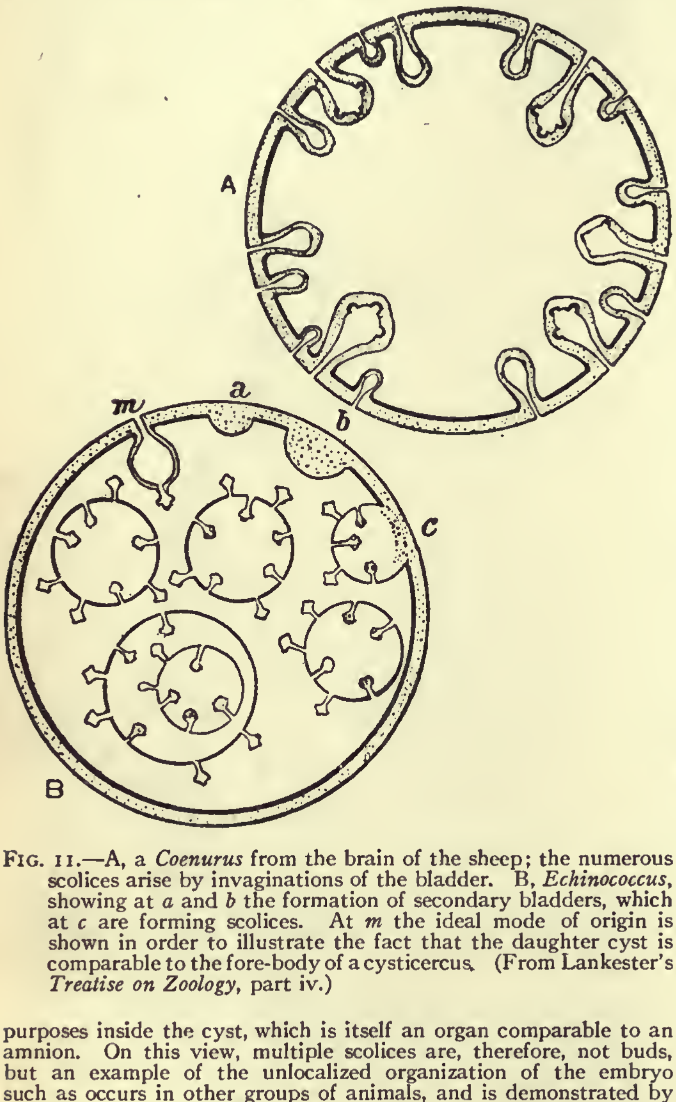

FIG. 11.—A, a *Coenurus* from the brain of the sheep; the numerous scolices arise by invaginations of the bladder. B, *Echinococcus*, showing at *a* and *b* the formation of secondary bladders, which at *c* are forming scolices. At *m* the ideal mode of origin is shown in order to illustrate the fact that the daughter cyst is comparable to the fore-body of a cysticercus. (From Lankester's *Treatise on Zoology*, part iv.)

The Effects of Cestodes on their Hosts (Shipley and Fearnsides [4].)—1. *By their presence.* This depends largely on the station adopted by the parasite. *Cysticercus cellulosae* may be comparatively innocuous in a muscle or subcutaneous tissue, but most hurtful in the eye or brain. Of all parasites the one which by its mere presence is the most dangerous is the larva of *Taenia echinococcus.* Its bulk alone (equal to that of an orange) causes serious disturbances, and its choice of the liver, kidneys, lungs, cranial cavity and other deep-seated recesses, gives rise to profound alterations.

2. *By their migrations.* The migration of the Cestode-larvae through the walls of the intestine into the blood of their host is the cause of grave disturbances, due largely to the perforation of the tissues, inflammation of the vessels and peritoneum, and other effects of these immigrants.

3. *By feeding in their host.* The loss of nutrient fluid caused by the presence of intestinal Cestodes is probably slight, indeed, the sharper appetite that accompanies their presence may be the means of fully compensating for it. The tapeworm, *Taenia saginata,* throws off eleven proglottides a day during its mature stage, and if this rate of increase were maintained for a year the total weight of its progeny would be about 550 grammes. The broad worm, *Dibothriocephalus latus,* is similarly estimated to discharge 15 to 20 metres of proglottides, weighing 140 grammes. The loss of substance represented by this growth is probably only of serious account when the host is a young growing animal that needs all available nourishment.

4. *By producing Toxins.* It is generally admitted that Cestodes, both adult and larval, contain toxins of great virulence, though in what way and in what organs these substances are produced is uncertain. Injection of the fluid-extract of such worms into the blood or coelom of their host causes grave disturbance. Thus Echinococci contains a leucomaine which sets up an urticaria; *Cysticercus tenuicollis* occasions anaemia and death if injected into rabbits; and the cystic fluid of the common *Coenurus serialis* is said to be used by Kirghizes to poison wolves. But the evidence in favour of the view that tapeworms normally excrete toxin into the body of their host in such amount as to occasion disease is not generally accepted as conclusive. This evidence is, however, strengthened by the results of recent work on changes in the blood of patients suffering from helminthiasis. The occurrence of the broad tapeworm in man is often associated with anaemia of a most severe type. The coloured constituents of the blood are most affected. New elements appear in addition to degenerative changes in the normal red corpuscles. Large nucleated red blood-cells make their appearance. The white blood-cells, or leucocytes, undergo other changes. In hydatid disease there is, as a rule, a marked increase in the number of those white corpuscles which possess a specially staining affinity with the dye eosin, and are therefore known as eosinophile cells. This change, which is called eosinophilia, indicates the production of a noxious substance in the blood. The fact of this increased leucocytic activity during the early stages, or the whole course of infection by Cestodes, is indirect proof that these parasites do normally discharge toxic substances into their hosts.

Classification of the Cestoda Merozoa

ORDER I.—*Dibothridiata.* Scolex with two "bothria," or modification thereof, usually devoid of hooks. Male and female copulatory ducts open by a common pore. Uterine pore present. The majority parasitic in fish. Selected forms: *Dibothriocephalus latus* in man; Russia, Switzerland, southern France, North America. *Ligula*, unsegmented externally, occurs in birds. *Schistocephalus* becomes fully segmented in *Gasterosteus* and mature in aquatic birds (ducks, &c.). *Triaenophorus*, indistinctly segmented, occurs in the pike.

ORDER II.—*Tetraphyllidea* (Tetrabothridiata). Scolex with four outgrowths forming organs of adhesion and probably also of locomotion. Uterine pore absent. Almost exclusively parasitic in the intestine of Elasmobranch fish. The metacestode-larva occurs free in the intestine of fish, Cephalopods and crabs, and is known as *Scolex polymorphus*.

ORDER III.—*Diphyllidea.* Scolex with a long head-stalk armed with several rows of hooklets. A rostellum and four phyllidia united to form a pair. Few proglottides are developed. Selected form: *Echinobothrium affine* in the intestine of Elasmobranchs. It occurs immature in the gastropod *Nassa.*

ORDER IV.—*Tetrarhyncha* (Trypanorhyncha). Scolex with four complex eversible proboscides. The adults occur in Elasmobranch fish, the metacestode encysted in Teleosts.

ORDER V.—*Tetracotylea* (Taeniidae). Scolex with four suckers, rarely hooked, and with a rostellum. Mostly parasitic in homoiothermic (warm-blooded) vertebrates. Selected forms: *Taenia solium*, intestine of man (fig. 3, C). *T. saginata* (fig. 3) without hooklets on the rostellum; intestine of man. *T. murina*, in the rat and mouse, the adult in the lumen of the intestine, the larvae in the villi. This species therefore undergoes no change of host. *Cystotaenia coenurus*, intestine of dog and wolf, larva (a coenurus, fig. 11) in the brain of sheep; allied forms occur mature in the dog and larval in the rabbit. *Echinococcifer echinococcus*, a minute form with only three to five proglottides, in dog, wolf, jackal. Larval stage a multilocular sac (fig. 11 B) with many scolices; found in man, ungulates, carnivores, rodents and monkeys.

Table of Cestodes found in Man

Species.	Larva.	Intermediate Host.
Dibothriocephalus latus (L.)	Plerocercoid	Pike, perch, trout, &c.
Dibothriocephalus cordatus (Leuck.)	Unknown	...
Diplogonoporus grandis (Blanch.)	,,	...
Dipylidium caninum (L.)	Cysticercoid	*Trichodectes canis; Pulex serraticeps; P. irritans*
Hymenolepis diminuata (Rud.)	Cysticercus	*Asopia farinalis*, *Anisolabis annulipes*, *Acisspinosa*, *Seaurus striatus* } Insecta
H. nana (v. Sieb.)	Cysticercus	Insects and myriapods
Drepanidotaenia lanceolata (Bloch)	Cysticercoid	*Cyclops*, *Diaptomus*
Davainea madagascarensis (Dav.)	Unknown	...
Davainea (?) *asiatica*	,,	...
Taenia solium (L.)	*Cysticercus cellulosae*	*Sus scrofa*
T. saginata (Götze)	*Cysticercus bovis*	*Bos taurus*
T. africana (v. Linst.)	Unknown	...
T. confusa (Ward)	,,	...
T. echinococcus (v. Sieb.)	*Echinococcus veterinorum*; *E. multilocularis*	Man and domestic cattle, sheep, pig
T. hominis (v. Linst.)	Unknown	...

Sci.* (Prague, 1897). Full references to further literature will be found in Braun's works. (F. W. GA.)

Medicine.—For practical purposes we have only three varieties of tapeworms to deal with as inhabitants of the human alimentary canal: *Taenia saginata*, the beef tapeworm; *Taenia solium*, the pork tapeworm; and *Dibothriocephalus latus*, the fish tapeworm. The first of these is prevalent in countries where much and imperfectly cooked beef is eaten, and where cattle in their turn are exposed to the infection of the tapeworm ova. Comparatively uncommon in Western Europe, the *Taenia saginata* is common in Eastern Europe, Asia and South America. It is calculated that in the North-West Provinces of India 5 per cent. of the cattle are affected with cysticerci owing to the filthy habits of the people. Measly beef (that infected with the *Cysticercus bovis*) is easily recognized. In Berlin the proportion of cattle said to be found infected on inspection in 1893 was 1 in 672. Cold storage for a period of over three weeks is said to kill the cysticercus.

The tapeworm most frequently found in man in Western Europe is the *Taenia solium*, which is constant wherever pork is consumed, and is more common in parts where raw or imperfectly cooked pork is eaten. In North Germany the mature tapeworm was found on post-mortem examination once in every 200 bodies examined, while its embryo, the *Cysticercus cellulosae*, was found in 1 in every 76 bodies. In France, Great Britain and the United States the prevalence is not so great. The *Dibothriocephalus latus* is not generally found except in districts bordering the Baltic Sea, the districts round the Franco-Swiss lakes and Japan. In St Petersburg 15 per cent. of the inhabitants are said to be affected. The eggs are free in fresh-water lakes and rivers, where they enter the bodies of pike, turbot and other fishes, and are thus eaten by man.

In many instances the existence of a tapeworm may not cause any inconvenience to its host, and its presence may be only made known by the presence of the proglottides or mature segments in the stools. In the *Taenia solium* it takes 3 to 3½ months from the time of ingestion of the embryo to the passage of the matured segments, but in the *Taenia saginata* the time is only about 60 days. The segments of the *Taenia solium* are usually given off in chains, those of the *Taenia saginata* singly. In a number of cases there are colicky pains in the abdomen, with diarrhoea or constipation and more or less anaemia, while the *Dibothriocephalus latus* is capable of producing a profound and severe anaemia closely resembling pernicious anaemia. The knowledge of the presence of the parasite adversely affects nervous people and may lead to mental depression and hypochondria. Nervous phenomena, such as chorea and epileptic seizures, have been attributed to the presence of the tapeworm.

The prophylaxis is important in order to limit the spread of the parasites. All segments passed should be burnt, and they should never be thrown where the embryos may become scattered. Attention should be paid to the careful cooking of meat, so that any parasite present should be killed. Efficient inspection of meat in the abattoirs should eliminate a large proportion of the diseased animals.

In the treatment of a case where the parasite is already present, for two days previous to the employment of a vermifuge a light diet should be given and the bowels moved by a purgative. For twelve hours previously to its administration no food should be given, in order that the intestinal tract should be empty so as to expose the tapeworm to the full action of the drug. The vermifuge is given in the early morning, and should consist of the liquid extract of felix mas, male fern, one drachm in emulsion or in capsules to be followed in half an hour by a calomel purgative. Castor-oil should not be used as a purgative. Pomegranate root, or, better, the sulphate of pelletierine in dose of 5 grains with an equal quantity of tannic acid, may be used to replace the male fern. In from 50 to 80 per cent. of cases the entire tapeworm is expelled. The head must be carefully searched for by the physician, as should it fail to be brought away the parasite continues to grow, and within a few months the segments again begin to appear.

TAPIOCA (a native Brazilian word), a farinaceous food substance prepared from cassava starch, the product of the large tuberous roots of the cassava or manioc plant (see CASSAVA). Cassava starch, separated from the fibrous and nitrogenous constituents of the roots, is spread, while in a moist condition, upon iron plates, and with constant stirring exposed to such heat as causes a partial rupture of the starch granules, which agglomerate into irregular pellets, becoming hard and translucent when cooled. In this condition the starch forms the tapioca of commerce, a light, pleasant and digestible food, much used in puddings and as a thickener for soups.

TAPIR, any existing representative of the perissodactyle section of ungulate mammals with five front and three hind toes, and no horn. Tapirs are an ancient group with many of the original characters of the primitive Ungulates of the Oligocene period, and have undergone but little change since the Miocene. On the fore-feet the four toes correspond to the second, third, fourth and fifth fingers of the human hand. The toes are enclosed in hoofs, and the under surface of the foot rests on a large pad. Tapirs are massively built, with short stout limbs, elongated head, and the nose and upper lip produced to form a short flexible trunk.

The five existing species may be grouped into two sections, the distinctive characters of which are only recognizable in the skull. (A) With a great anterior prolongation of the ossification of the nasal partition, extending in the adult far beyond the nasal bones, and supported and embraced at the base by ascending plates from the upper jaw, forming the genus or sub-genus *Tapirella*. To this division belong two species, both from Central America, *Tapirus bairdi* and *T. dowi*. The former is found in Mexico, Honduras, Nicaragua, Costa Rica and Panama; the latter in Guatemala, Nicaragua and Costa Rica. (B) With the bony partition not extending farther forward than the nasal bones (*Tapirus* proper). This includes three species, *T. indicus*, the largest of the genus, from the Malay Peninsula (as far north as Tavoy and Mergui), Sumatra and Borneo, distinguished by its peculiar coloration, the head, neck, fore and hind limbs being glossy black, and the intermediate part of the body white, the height at the shoulder from 3 ft. to 3 ft. 6 ins., and 4 ins. higher at the rump; *T. terrestris*, the common tapir of the forests and lowlands of Brazil and Paraguay; and *T. roulini*, the Pinchaque tapir of the high regions of the Andes. All the American species are of a nearly uniform dark brown or blackish colour when adult; but it is a curious circumstance that when young (and in this the Malay species conforms with the others) they are conspicuously marked with spots and longitudinal stripes of white or fawn colour on a darker ground.

In habits all tapirs appear to be very similar. They are solitary, nocturnal, shy and inoffensive, chiefly frequenting the depths of shady forests and the neighbourhood of water, to which they frequently resort for the purpose of bathing, and in which they often take refuge when pursued. They feed on various vegetable substances, as shoots of trees and bushes,

American Tapir (*Tapirus*).

buds and leaves, and are hunted by the natives of the lands in which they live for the sake of their hides and flesh.

The singular fact of the existence of animals so closely allied as the Malayan and the American tapirs in such distant regions of the earth and in no intervening places is accounted for by the geological history of the race, for the tapirs once had a very wide distribution. There is no proof of their having lived in the Oligocene epoch, but in deposits of Miocene and Pliocene date remains undistinguishable generically and perhaps specifically from the modern tapirs (though named *T. priscus*, *T. arvernensis*, &c.) have been found in France, Germany and in the Red Crag of Suffolk. Tapirs appear, however, to have become extinct in Europe before the Pleistocene period, as none of their bones or teeth have been found in any of the caves or alluvial deposits in which those of elephants, rhinoceroses and hippopotamuses occur in abundance; but in other regions their distribution at this age was far wider than at present, as they are known to have extended eastward to China (*T. sinensis*) and westwards over the greater part of the southern United States of America, from South Carolina to California. Thus there is no difficulty in tracing the common origin in the Miocene tapirs of Europe of the now widely separated American and Asiatic species. It is, moreover, interesting to observe how slight an amount of variation has taken place in forms isolated during such an enormous time. See PERISSODACTYLA. (W. H. F.; R. L.*)

TAPTI, a river of western India. It rises in Betul district of the Central Provinces, flows between two spurs of the Satpura Hills, across the plateau of Khandesh, and thence through the plain of Surat to the sea. It has a total length of 450 m. and drains an area of 30,000 sq. m. For the last 32 m. of its course it is a tidal river, but is only navigable by vessels of small tonnage; and the port of Swally at its mouth, famous in Anglo-Portuguese history, is now deserted, owing to silting at the outflow of the river. The waters of the Tapti are nowhere used for irrigation.

TAR, a product of the destructive distillation of organic substances. It is a highly complex material, varying in its composition according to the nature of the body from which it is distilled,—different products, moreover, being obtained according to the temperature at which the process of distillation is carried on. As commercial products there are two principal classes of tar in use—(1) wood tar, the product of the special distillation of several varieties of wood, and (2) coal tar (*q.v.*), which is primarily a by-product of the distillation of coal during the manufacture of gas for illuminating purposes. These tars are intimately related to bitumen, asphalt, mineral pitch and petroleum.

Wood Tar.—Wood tar, known also as Stockholm and as Archangel tar, is principally prepared in the great pine forests of central and northern Russia, Finland and Sweden. The material chiefly employed is the resinous stools and roots of the Scotch fir (*Pinus sylvestris*) and the Siberian larch (*Larix sibirica*), with other less common fir-tree roots. A large amount of tar is also prepared from the roots of the swamp pine (*P. australis*) in North and South Carolina, Georgia and Alabama, in the United States. In the distillation of wood a series of products, including gas, tar, pyroligneous acid, acetone, wood spirit (see METHYL ALCOHOL) and charcoal may be obtained, and any of these may be the primary object of the operation.

The carbonization of wood can be effected in two ways: (1) by stacking and firing as in the manufacture of charcoal: this method is very wasteful as it is impossible to recover the valuable by-products; and (2) by distilling from retorts, ovens or kilns (after the manner of coke production from coal): this method is more economical as it leads to the isolation of all the by-products. The retorts may be horizontal or vertical and the heating effected by any available fuel, or by the inflammable gases and less valuable grades of tar obtained in previous operations. The condensing plant is also of variable design; a common pattern consists of a connected series of slightly inclined copper pipes contained in a rectangular tank of water (see COAL TAR). After settling the distillate separates into three layers: the lowest consists chiefly of tar and creosote oils with a little acetic acid; the middle layer consists of water, containing pyroligneous acid, wood spirit, acetone with a little tarry matter; whilst the upper consists of light hydrocarbons. The tarry layer is run off by means of a cock near the base of the tank, and is then distilled from retorts resembling coal tar stills. At first, between 110° and 120° C., water and acetic acid comes over; then, between 120°—230° C., the heavy or creosote oils; the residue in the still is wood pitch, which finds application in making briquettes, artificial asphalts, certain varnishes, &c. The crude tar and pitch are also largely used as protective coatings for woodwork exposed to atmospheric conditions. The heavy oils on further fractional distillation yield more acetic acid, and then mixtures of carbolic acid, creosols, &c.

Wood tar is a semi-fluid substance, of a dark brown or black colour, with a strong pungent odour and a sharp taste. Owing to the presence of acetic acid, it has an acid reaction; it is soluble in that acid, as well as in alcohol and the fixed and essential oils, &c. Some varieties of tar have a granular appearance, from the presence of minute crystals of pyrocatechin, which dissolve and disappear on heating the substance.

See P Dumesny and J. Noyer, *Wood Products, Distillates and Extracts* (Engl. trans. 1908).

Medicine.—Wood tar is used in medicine under the name of *Pix liquida*. Its preparation *unguentum picis liquidae* is composed of wood tar and yellow beeswax. Externally tar is a valuable stimulating dressing in scaly skin diseases, such as psoriasis and chronic eczema. Internally wood tar is a popular remedy as an expectorant in subacute and chronic bronchitis. It is usually given as tar water, 1 part of wood tar being stirred into 4 parts of water and filtered. Given internally tar is likely to upset the digestion; taken in large quantities it causes pain and vomiting and dark urine, symptoms similar to carbolic acid poisoning.

Coal tar is used in medicine as *Pix liquida preparata*. From it is made *Liquor picis carbonis*, prepared with tincture of quillaia. Coal tar is rarely prescribed for internal use. Its external use is similar to that of wood tar: the *Liquor carbonis detergens*, a proprietary preparation, owes its properties chiefly to the contained phenol. It is used in water as a lotion for skin diseases, and also in an inhaler in the treatment of whooping-cough, croup and bronchitis.

TARA, VISCOUNTS AND BARONS. The 1st Viscount Tara was Thomas Preston (1585–1655), a descendant of Sir Robert de Preston, who in 1363 purchased the lands of Gormanston, Co. Meath, and who was keeper of the Great Seal in Ireland some years later. Sir Robert's great-grandson, Robert Preston, was created Viscount Gormanston in 1478; and the latter's great-grandson was Christopher, 4th Viscount Gormanston (d. 1599), whose second son was Thomas Preston, Viscount Tara. The latter was in the same Irish regiment in the Spanish service as Owen Roe O'Neill, and distinguished himself in the defence of Louvain against the French and Dutch in 1635. Between him and Owen Roe O'Neill there was from the first intense jealousy. Preston, who was appointed general of Leinster, took a prominent and not unsuccessful part in the war of factions that raged intermittently in Ireland from 1642 to 1652. In 1650 Charles II. while in exile created him Viscount Tara; and after his departure from Ireland in 1652 he offered his services to Charles in Paris, where he died in October 1655. His wife was a Flemish lady of rank, by whom he had several children, one of his daughters being the second wife of Sir Phelim O'Neill. His son Anthony succeeded him as 2nd Viscount Tara, a title that became extinct on the death of Thomas, 3rd Viscount, in 1674.

In 1691 Meinhart de Schomberg, 3rd duke of Schomberg, second son of William III.'s famous general, was created Baron Tara, earl of Bangor, and duke of Leinster, in the peerage of Ireland, all of which titles became extinct at his death without sons in 1719. The title of Baron Tara was again revived in 1800 in favour of John Preston of Bellinter, Co. Meath, as a reward for his vote in favour of the Union in the Irish House of Commons, in which he sat as member for Navan. At his death without issue in 1821, the peerage became extinct.

TARA, a village of Co. Meath, Ireland. It is celebrated for the Hill of Tara, well known through Thomas Moore's ballad, and for many centuries a royal residence and the scene of great meetings of the people. The hill, upon which five highroads converged from different parts of Ireland, is about 510 ft. in height, and stands isolated. On its summit or flanks are six raths or circular earthworks, the largest of which, called the king's rath (*rath-na-riogh*) encloses other works, among which is the *forradh* or meeting-place, a flat-topped mound. On this (but not in its original position) stands a pillar stone, which has been held to be the stone of destiny on which the Irish kings were crowned. An oblong enclosure, 759 ft. in length by 46 ft. in breadth, formed of earthworks, with entrances at intervals on each side, represents the banqueting hall. In the middle of the 3rd century A.D. King Cormac Mac Art, about whom there are many records in connexion with Tara, is said to have founded here schools of military science, law and literature. In the time of St Patrick Tara is indicated as the chief seat of druidism and idolatry, and in or about 560 it was abandoned as a royal residence, having fallen under the curse of St Ruadan. In 980 the Danish power of Meath was overthrown in battle here; in 1798 a severe defeat of the insurgents took place here (26th of May); and in 1843 the hill of Tara, as a site sacred to Irish traditions, was the scene of one of Daniel O'Connell's mass meetings in support of the repeal of the legislative union (15th of August).

TARAFA ['Amr ibn ul-'Abd ul-Bakrī] (6th cent.), Arabian poet, who, after a wild and dissipated youth spent in Bahrein, left his native land after peace had been established between the tribes of Bakr and Taghlib and went with his uncle Mutalammis (also a poet) to the court of the king of Hira, 'Amr ibn Hind (died 568–9), and there became companion to the king's brother. Having ridiculed the king in some verses he was sent with a letter to the ruler of Bahrein, and, in accordance with the instructions contained in the letter, was buried alive. One of his poems is contained in the *Moallakat* (*q.v.*).

His diwan has been published in W. Ahlwardt's *The Diwans of the Six Ancient Arabic Poets* (London, 1870). Some of his poems have been translated into Latin with notes by B. Vandenhoff (*Berlin*, 1895). (G. W. T.)

TARAI, or TERAI (*i.e.* "moist land"), the name of the submontane strip of marshy jungle stretching beneath the lower ranges of the Himalaya in northern India. This strip may be said to extend roughly from the Jumna river on the west to the Brahmaputra on the east, though the term is now officially confined to a subdivision of Naini Tal district in the United Provinces; area, 776 sq. m.; population (1901) 118,422. At its northern edge, where the waterless forest tract of the Bhabar ends, a series of springs burst from the surface, and these, increasing and uniting in their progress, form the numerous streams that intersect the Tarai. The Deoha is the great river of the Tarai proper, and is navigable at Pilibhit. Elephants, tigers, bears, leopards and other wild animals are found. Everywhere it is most unhealthy, and inhabited only by tribes who seem proof against malaria. A large portion lies within Nepal.

TARANTO (anc. *Tarentum*, *q.v.*), a seaport of Apulia, Italy, in the province of Lecce, 50 m. from that town W. by N. by road, and 68 m. by rail (44 m. W. by S. from Brindisi). Pop. (1901) 50,592 (town); 60,331 (commune). The city proper is situated on a rocky island 56 ft. above sea-level, which in ancient times was a peninsula, the isthmus on the west having been cut through by Ferdinand I. of Aragon. This island separates the Gulf of Taranto from the deep inlet of the Mare Piccolo, and is sheltered by two other flat islands, San Pietro and San Paolo; the latter is occupied by a lighthouse. This rock is the site of the citadel of the ancient town; its population is confined within small houses and narrow streets. The Strada Garibaldi along the Mare Piccolo is inhabited by fishermen whose language retains traces of Greek. The cathedral, dedicated to San Cataldo, an Irish bishop, dating from the 11th century, has externally some remains of Saracenic Gothic; internally it has been completely modernized, and the shrine of the patron saint has been termed "an orgy of rococo." Below it is an early Christian basilica excavated in 1901. There is a fine museum in the former convent of San Pasquale containing antiquities unearthed in the neighbourhood. Adjacent is the Palazzo degli Uffizi, completed in 1896, containing various public offices. To the south, outside the Porta di Lecce, is the Citta Nuova, on the site of the main part of the ancient town. The chief industry is the cultivation of oysters in four large beds in the Mare Piccolo; besides oysters, Taranto carries on a large trade in *cozze*, a species of large black mussel, which is packed in barrels with a special sauce. The other trades are olive-oil refining, barrel-making and soap-boiling; corn, honey and fruit are largely exported. Excellent fish abound in the Mare Piccolo, ninety-three different species being found. The ebb and flow of the tide is distinctly visible here, Taranto being one of the few places in the Mediterranean where it is perceptible. In 1861 the strategic importance of Taranto was recognized by the Italian government, and in 1864 a Naval Commission designated it as third maritime arsenal after Spezia and Venice. Work was begun on the arsenal in 1883 and continued as the finances of the state permitted; it is capable of turning out new warships and of executing repairs of all kinds for the Mediterranean squadron. The arsenal extends for a mile and a half along the southern coast of the Mare Piccolo, which constitutes its chief basin. The receiving-dock and the anchorage for torpedo boats, with its wide landing-stage, form dependencies. The dock, 655 ft. long, 130 ft. wide and 37 ft. deep, is divided into two compartments, each capable of containing a full-sized battleship, and can be pumped dry in eight hours by two 600 h.p. steam pumps. The Mare Grande is connected with the Mare Piccolo by a channel 875 yds. long, large enough to permit the passage of the largest battleship; the channel was bridged in 1887 by an iron swivel bridge, which when open leaves a passage way 196 ft. broad. In its present form the Mare Piccolo provides a well-sheltered anchorage, 36 ft. deep and 6325 acres in extent. The commercial harbour lies S. of the railway station outside the Mare Piccolo. In 1905 nearly 180,000 tons of shipping cleared the port.

In 927 Taranto was entirely destroyed by the Saracens, but rebuilt in 967 by Nicephorus Phocas, to whom is due the construction of the bridge over the channel to the N.W. of the town, and of the aqueduct which passes over it. The town was taken by Robert Guiscard in 1063. His son Bohemond became prince of the Terra d'Otranto, with his capital here. After his death Roger II. of Sicily gave it to his son William the Bad. The emperor Frederick II. erected a castle (Rocca Imperiale) at the highest point of the city. In 1301 Philip, the son of Charles II. of Anjou, became prince of Taranto. The castle dates from the Aragonese period. The tarantula (see below), inhabits the neighbourhood of Taranto. The wild dance, called *tarantella*, was supposed, by causing perspiration, to drive out the poison of the bite. (T. As.)

TARANTULA, strictly speaking, a large spider (*Lycosa tarantula*), which takes its name from the town of Taranto (Tarentum) in Apulia, near which it occurs and where it was formerly believed to be the cause of the malady known as "tarantism." This spider belongs to the family Lycosidae, and has numerous allies, equalling or surpassing it in size, in various parts of the world, the genus *Lycosa* being almost cosmopolitan in distribution. The tarantula, like all its allies, spins no web as a snare but catches its prey by activity and speed of foot. It lives on dry, well-drained ground, and digs a deep burrow lined with silk to prevent the infall of loose particles of soil. In the winter it covers the orifice of this burrow with a layer of silk, and lies dormant underground until the return of spring. It also uses the burrow as a safe retreat during moulting and guards its cocoon and young in its depths. It lives for several years. The male is approximately the same size as the female, but in neither sex does the length of the body surpass three-quarters of an inch. Like all spiders, the tarantula possesses poison glands in its jaws, but there is not a particle of trustworthy evidence that the secretion of these glands is more virulent than that of other spiders of the same size, and the medieval belief that the bite of the spider gave rise to tarantism has long been abandoned. According to traditional accounts the first symptom of this disorder was usually a state of depression and lethargy. From this the sufferer could only be roused by music, which excited an overpowering desire to dance until the performer fell to the ground bathed in profuse perspiration, when the cure, at all events for the time, was supposed to be effected. This mania attacked both men and women, young and old alike, women being more susceptible than men. It was also considered to be highly infectious and to spread rapidly from person to person until whole areas were affected. The name tarantella, in use at the present time, applies both to a dance still in vogue in Southern Italy and also to musical pieces resembling in their stimulating measures those that were necessary to rouse to activity the sufferer from tarantism in the middle ages. In recent times the term tarantula has been applied indiscriminately to many different kinds of large spiders in no way related to *Lycosa tarantula*; and to at least one Arachnid belonging to a distinct order. In most parts of America, for example, where English is spoken, species of Aviculariidae, or "Bird-eating" spiders of various genera, are invariably called tarantulas. These spiders are very much larger and more venomous than the largest of the Lycosidae, and in the Southern states of North America the species of wasps that destroy them have been called tarantula hawks. In Queensland one of the largest local spiders, known as *Holconia immanis*, a member of the family Clubionidae, bears the name tarantula; and in Egypt it was a common practice of the British soldiers to put together scorpions and tarantulas, the latter in this instance being specimens of the large and formidable desert-haunting Arachnid, *Galeodes lucasii*, a member of the order Solifugae. Similarly in South Africa species of the genus *Solpuga*, another member of the Solifugae, were employed for the same purpose under the name tarantula. Finally the name *Tarantula*, in a scientific and systematic sense, was first given by Fabricius to a Ceylonese species of amblypygous Pedipalpi, still sometimes quoted as *Phrynus lunatus*. (R. I. P.)

Galeodes lucasii, an Arachnid of the order Solifugae, commonly but wrongly called tarantula in Egypt.

TARAPACÁ, a northern province of Chile, bounded N. by Tacna, E. by Bolivia, S. by Antofagasta, and W. by the Pacific. Area 18,131 sq. m. Pop. (1895) 89,751; (1902, estimated) 101,105. It is part of the rainless desert region of the Pacific coast of South America, and is absolutely without water except at the base of the Andes where streams flow down into the sands and are lost. In some of these places there is vegetation and water enough to support small settlements. The wealth of Tarapacá is in its immense deposits of nitrate of soda (found on the Pampa de Tamarugal, a broad desert plateau between the coast range and the Andes, which has an elevation of about 3000 ft.). The mining and preparation of nitrate of soda for export maintain a large population and engage an immense amount of capital. Silver is mined in the vicinity of Iquique, the capital. The ports of the province are Pisagua, Iquique and Patillos, from which "nitrate railways" run inland to the deposits. Tarapacá was ceded to Chile by Peru after the war of 1879–1883, and was organized as a province in 1884.

TARARE, a town of east-central France, in the department of Rhone, on the Turdine, 28 m. W.N.W. of Lyons by rail. Pop. (1906) 11,643. It is the centre of a region engaged in the production of muslins, tarletans, embroidery and silk-plush, and in printing, bleaching and other subsidiary processes. Till 1756, when the manufacture of muslins was introduced from Switzerland, the town lay unknown among the Beaujolais mountains. The manufacture of Swiss cotton yarns and crochet embroideries was introduced at the end of the 18th century; at the beginning of the 19th figured stuffs, open-works and zephyrs were first produced. The manufacture of silk-plush for hats and machine-made velvets was set up towards the end of the 19th century. A busy trade is carried on in corn, cattle, linen, hemp, thread and leather.

TARASCON, a town of south-eastern France, in the department of Bouches-du-Rhone, 62 m. N.W. of Marseilles by rail. Pop. (1906) town, 5447; commune, 8972. Tarascon is situated on the left bank of the Rhone opposite Beaucaire, with which it is connected by a railway bridge and a suspension bridge. The church of St Martha, built in 1187–97 on the ruins of a Roman temple and rebuilt in 1379–1449, has a Gothic spire, and many interesting pictures in the interior. Of the original building there remain a porch, and a side portal flanked by marble columns with capitals like those of St Trophimus at Arles. The former leads to the crypt, where are the tombs of St Martha (1658), Jean de Gossa, governor of Provence under King René, and Louis II., king of Provence. The castle, picturesquely situated on a rock, was begun by Count Louis II. in the 14th century and finished by King René in the 15th. It contains a turret stair and a chapel entrance, which are charming examples of 15th-century architecture, and fine wooden ceilings. The building is now used as a prison. The hôtel-de-ville dates from the 17th century. The civil court of the arrondissement of Arles is situated at Tarascon, which also possesses a commercial court, and fine cavalry barracks. The so-called Arles sausages are made here, and there is trade in fruit and early vegetables. In *Tartarin de Tarascon* Alphonse Daudet has satirized the provincial life of Tarascon. Its uneventfulness is varied by the fair of Beaucaire, and it used to be the scene of the two fêtes of La Tarasque, the latter in celebration of St Martha's deliverance of the town from a legendary monster of that name. King René presided in 1469, and grand exhibitions of costume and strange ceremonies take place during the two days of the festival. Tarascon was originally a settlement of the Massaliots, built on an island of the Rhone. The medieval castle, where Pope Urban II. lived in 1096, was built on the ruins of a Roman camp. The inhabitants of Tarascon preserved the municipal institutions granted them by the Romans, and of the absolute power claimed by the counts of Provence they only recognized the rights of sovereignty. Tarascon played a bloody part in the White Terror of 1815.

TARAXACUM, the name usually applied in medical practice to the common dandelion (*q.v.*).

TARBELL, EDMUND C. (1862–), American artist, was born at West Groton, Mass., on the 26th of April 1862. He was a pupil of the schools of the Boston Museum of Fine Arts and of Boulanger and Lefebvre, Paris, and became a distinguished painter of the landscape, of the figure, and of portraits, winning various important prizes and medals at exhibitions. In 1906 he was elected a National Academician, besides being a member of the Ten American Painters, and he became instructor of painting in the Boston Museum of Fine Arts.

TARBERT, a fishing village at the head of East Loch Tarbert, an arm of the sea on the west shore of the mouth of Loch Fyne, Argyllshire, Scotland. Pop. (1901) 1697. The harbour, though it has a narrow entrance, is absolutely safe and can shelter the whole of the Loch Fyne fishing fleet. The pier for the passenger steamers that call here is about ¾ m. from the village. The coast of the bay is rocky and the cliffs are fringed with young firs, the village itself being quite a pretty place. The herring fishery—including a large trade in curing—forms the only industry. The parish church occupies a fine situation. Overlooking the harbour are the ruins of a castle built by Robert Bruce in 1326. The isthmus connecting the districts of Knapdale and Kintyre is little more than one mile wide, and boats used once to be dragged across to the head of West Loch Tarbert, a narrow sea loch nearly ten miles long. A proposal to cut a canal across to shorten the sail to Islay and Jura has never progressed further.

TARBES, a town of south-western France, capital of the department of Hautes-Pyrénées, 98 m. W.S.W. of Toulouse on the Southern railway. Pop. (1906) town, 20,866; commune, 25,869. Tarbes is situated in a beautiful and fertile plain, in full view of the Pyrenees, on the left bank of the Adour, streams from which are conducted through all parts of the town. The lines of the Southern railway from Morcenx to Bagnères-de-Bigorre and Lourdes and from Toulouse to Bayonne cross here. Chief among the many open spaces is the Jardin Massey (35 acres), given to his native town by a director of the gardens of Versailles and containing a museum of sculptures, paintings and antiquities. Near a small lake stands a cloister (15th century) transferred from the abbey of St Sever-de-Rustan, 14 m. N.E. of Tarbes, and a bust of Théophile Gautier, a native of Tarbes. The architecture of the cathedral, Notre Dame de la Sède, is heavy and unpleasing, but the cupola of the transept (14th century), the modern glass in the 12th-century apse, and a rose window of the 13th century, in the north transept, are worthy of notice. There is also a modernized Carmelite church originally built in the 13th century. Tarbes is a well-known centre for the breeding of Anglo-Arabian horses, much used by light cavalry; and its stud is the most important in the south of France. The industrial establishments include tanneries, tile-works, saw-mills and turners' shops. There are important fairs and markets. Well-known race-meetings are held on the Laloubère course.

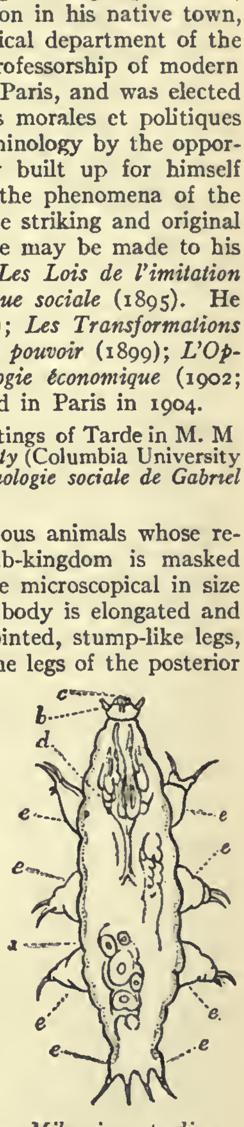
Under the Roman dominion *Turba*, which was about 11 m. S.E. of the present town of Tarbes, was the capital of the Bigerriones, one of the states of Novempopulania. The bishopric of Tarbes dates from the 5th century, and in feudal times its bishops held the chief temporal authority, that of the counts of Bigorre, of which Tarbes was capital, being limited to the quarter of the town where their castle was built. The English held the town from 1360 to 1406. In 1569 Tarbes was burnt by Gabriel, count of Montgomery, and the inhabitants were driven out. This happened a second time, but in August 1570 the peace of St Germain allowed them to return. Subsequently Tarbes was several times taken and re-taken, and a number of the inhabitants of Bigorre were forced to take refuge in Spain, but in 1594 the members of the League were finally expelled. The English, under Wellington, gained a victory over the French near Tarbes in 1814.

TARBUSH (Arab *tarbūsh*), the close-fitting, flat-topped and brimless cap, in shape like a truncated cone, made of felt or cloth, worn by Mahommedan men throughout the East either as a separate headgear or forming the inner part of the turban. It is worn as the badge of a Turkish subject in Turkey and Egypt, where it is red in colour with a black or blue silk tassel. It is the same as the "fez" (see the plate illustrations to INDIA: § *Indian Costume*).

TARDE, GABRIEL (1843–1904), French sociologist, was born at Sarlat (Dordogne) in 1843. Entering the legal profession, he was for some time a juge d'instruction in his native town, becoming afterwards head of the statistical department of the ministry of justice. He also held the professorship of modern philosophy at the Collège de France in Paris, and was elected a member of the Académie des sciences morales et politiques in 1900. Attracted to the study of criminology by the opportunities of his profession, he gradually built up for himself a reputation as an acute observer of the phenomena of the subject, while at the same time he made striking and original deductions of his own. Special reference may be made to his theory of "imitation" as outlined in *Les Lois de l'imitation* (1890), and further elaborated in *Logique sociale* (1895). He also wrote *L'Opinion et la foule* (1901); *Les Transformations du droit* (1894); *Les Transformations du pouvoir* (1899); *L'Opposition universelle* (1897) and *Psychologie économique* (1902; Eng. trans., *Social Laws*, 1899). He died in Paris in 1904.

See bibliography of the sociological writings of Tarde in M. M Davis, *Psychological Interpretations of Society* (Columbia University Press, 1909); also A. Matagrin, *La Psychologie sociale de Gabriel Tarde* (Paris, 1910).

TARDIGRADA, apparently Arthropodous animals whose relationship to the great classes of this sub-kingdom is masked by degenerative modification. They are microscopical in size and live in damp moss or water. The body is elongated and furnished with four pairs of short, unjointed, stump-like legs, each terminated by a pair of claws. The legs of the posterior pair project from the hinder extremity of the body and the anus opens between them. The mouth, situated at the opposite end and armed with a pair of stylets, leads into an oesophagus, into which the ducts of a pair of so-called salivary glands open. Behind this point there is a muscular pharynx or gizzard, which communicates with the wide intestinal tract. No organs of circulation or respiration are known; but the nervous system is well developed, and consists of a pair of ganglia corresponding with the limbs and connected by longitudinal commissural chords. Anteriorly these chords embrace the oesophagus and unite with the cerebral mass which innervates the pair of eyes when present. The sexes are not distinct, the sexual organs being represented by a pair of testes and a single ovary, which open together into the posterior end of the alimentary canal. The Tardigrada have been regarded as degenerate Acari largely on account of their possessing four pairs of ambulatory limbs, which is considered



Milnesium tardigradum, Schrank. *a*, ovary; *b*, oval stylite (?); *c*, mouth; *d.*, alimentary canal; *e...e*, legs.

to be an Arachnidan characteristic. But they cannot be affiliated with this order on account of the total suppression of the abdomen, of their hermaphroditism and of the communication that exists between the generative organs and the alimentary tract. These last characteristics also separate them essentially from the Pycnogonida, some members of which resemble them to a certain extent in having only four pairs of limbs, no gnathites, no respiratory organs, a ganglionated ventral nervous system, and the abdomen reduced to a mere rudiment projecting between the last pair of legs.

Several genera and species of Tardigrada have been described, perhaps the best known being *Macrobiotus schultzii* and *Milnesium tardigradum*. (R. I. P.)

TARE AND TRET, in commerce, allowances or deductions. Tare is an allowance made from the gross weight of goods for the box, bag or other wrapping in which the goods are packed. It may be *real*, *i.e.* representing the actual weight of the wrapping; *customary*, when a uniform or established rate is allowed; *average*, when one or two packages among several are weighed, and the mean or average of the whole taken; or *super-tare*, an additional allowance when the package exceeds a certain weight. Tret is an allowance of 4 lb. in every 104 lb. of weight, made as compensation for loss by waste. "Tare" comes through the Fr. *tare*, cf. Sp. *tara*, from Arab. *ṭarha*, *ṭarh*, throwing, casting—the word meant originally loss, that which is thrown away; "tret" is an adaptation of Fr. *traite*, Lat. *trahere*, to draw, and meant a draught, transportation, also a payment on exports, an allowance on exportation.

TARENTUM (Gr. *τάρας*), a Greek city of southern Italy (mod. Taranto, *q.v.*), situated on the N. coast of the gulf of the same name, on a rocky islet at the entrance to the only secure harbour in it. It was a Spartan colony founded about the close of the 8th century B.C. (Jerome gives the date 708) to relieve the parent state of a part of its population which did not possess, but claimed to enjoy, full civic rights. Legend represents these *Partheniae* (so they are called) as Spartans with a stain on their birth, but the accounts are neither clear nor consistent, and the facts that underlie them have not been cleared up. The Greeks were not the first settlers on the peninsula: excavations have brought to light signs of a pre-Hellenic settlement. To the Greeks Taras was a mythical hero, son of Neptune, and he is sometimes confounded with the oecist (official founder) of the colony, Phalanthus. Situated in a fertile district, especially famous for olives and sheep, with an admirable harbour, great fisheries and prosperous manufactures of wool, purple[1] and pottery, Tarentum grew in power and wealth and extended its domain inland. Even a great defeat by the natives in 473 B.C., when more Greeks fell than in any battle known to Herodotus, did not break its prosperity, though it led to a change of government from aristocracy to democracy. A feud with the Thurians for the district of the Siris was settled in 432 by the joint foundation of Heraclea, which, however, was regarded as a Tarentine colony. In the 4th century Tarentum was the first city of Magna Graecia, and its wealth and artistic culture at this time are amply attested by its rich and splendid coins; the gold pieces in particular (mainly later than 360) are perhaps the most beautiful ever struck by Greeks (see NUMISMATICS). In the second half of the century Tarentum was in constant war with the Lucanians, and did not hold its ground without the aid of Spartan and Epirote *condottieri*. Then followed war with Rome (281) in consequence of the injudicious attack of the mob on the Roman fleet in the harbour of Tarentum and on the Roman garrison at Thurii, the expedition of Pyrrhus, whom Tarentum summoned to its aid, and at length, in 272, the surrender of the city by its Epirote garrison. Tarentum retained nominal liberty as an ally of Rome. In the Second Punic War it went over to Hannibal in 212, and suffered severely when it was retaken and plundered by Fabius (209), who sold thirty thousand citizens as slaves. After this it fell into decay, but revived again after receiving a colony in 123 B.C., which received the name of Neptunia. In the time of Augustus it was essentially Greek and a favourite place of resort (Horace, *Od.*, iii. 5, 53), but it declined afterwards. Belisarius ordered it to be re-fortified, but it was soon taken by Totila, who made it his treasure store. After his defeat by Narses, it was sold to the Byzantine Empire by its Gothic governor.

One of the most interesting discoveries of recent years has been that of a *terramara* on the so-called Scoglio del Tonno on the N.W. of the town, which in its type and in the character of the objects found there, is exactly identical with the *terremare* of the Po valley. It seems, however, to be an isolated colony, and not to prove a parallel development in north and south Italy (T. E. Peet in *Papers of the British School at Rome*, iv., 1907, 285). Almost the only relic of any building of the Greek city is a part of a Doric temple on the island—which the modern town occupies—two fluted columns, with a lower diameter of 6⅔ ft., and a height of 28 ft., and some fragments of the entablature, belonging probably to the beginning of the 6th century B.C., so that this is one of the earliest extant Doric temples. The condition of the site was, however, different in ancient times; the rock occupied by the modern town was, it is true, the citadel, but was connected with the land to the west by an isthmus, which was only cut through by Ferdinand I. of Aragon; and it was also a good deal less extensive. The line of the walls which defended the city on the east (land) side has been traced, and a few remains of well-cut blocks, with Greek masons' marks, still exist. In the centre of the Agora was the huge bronze Zeus by Lysippus, and facing on to it the Ποικιλή, or painted portico, with pictorial representations of the life of Phalanthus, and the foundation of the city, and the museum. There was also a fine gymnasium and other buildings mentioned by classical writers. Strabo's description of the site (vi. 3, 1) is a good one. Of all these structures no traces remain. The Roman amphitheatre, on the other hand, and remains of Roman baths by the seashore, have been found; the former perhaps occupies the site of the ancient theatre, in which the Roman ambassador was received in 281 B.C.

Three fine mosaics of the Roman period were found in the remains of a house in 1899, and transported to the museum (A. Avena, *Monumenti dell' Italia Meridionale*, Naples, 1903, 239). A fine silver jug and drinking-horn, found in Tarentum in 1889 (now in Triest) are illustrated by A. Puschi and F. Winter in *Jahreshefte des Österr. Arch. Instituts*, v. (1902) 112. Other silver vessels found in 1896 are in the important local museum (G. Patroni in *Notizie degli scavi*, 1896, 376), and at Bari (M. Mayer, *ibid.*, 1896, 547). All seem to belong to the 4th century B.C. To the N.W. of the town along the Massafia road, neolithic tombs and a fine Greek hypogaeum in masonry were discovered in 1900. (T. As.)

TARENTUM, a borough of Allegheny county, Pennsylvania, U.S.A., on the Allegheny river, about 20 m. N.E. of Pittsburg. Pop. (1890) 4627; (1900) 5472 (1173 being foreign-born); (1910) 7414. Tarentum is served by the Pennsylvania railway and by an electric line connecting with Pittsburg. Among manufactures are plate glass and bottles, table ware, paper, bricks, iron and steel articles, and steel sheets and billets. Coal mining is an important industry, and the borough is supplied with natural gas. Tarentum was first settled in 1796, was laid out in 1829 at the direction of Henry Marie Brackenridge (1786–1871),[2] who by marriage had come into possession of the site, and it was incorporated as a borough in 1842. The first glass manufactory was established in 1872.

TARGET, GUI JEAN BAPTISTE (1733–1807), French lawyer and politician, was born in Paris on the 17th of December 1733.

[1] Large heaps of the shells of the *murex*, or purple-yielding mussel, were visible on the shore before the extension of the arsenal.

[2] Brackenridge was a prominent lawyer, a native of Pittsburg, who practised in Maryland, Missouri and Louisiana, was a district judge in Louisiana in 1812–1814, secretary of the U.S. commission sent to South America in 1817, U.S. judge for the western district of Florida from 1821 to 1832, when he returned to Pennsylvania, and the author of a *Voyage to South America in 1817–1818* (1820), a *History of the Late War between the United States and Great Britain* (1817), *Recollections of Persons and Places in the West* (1834), and a *History of the Western Insurrection* (1859).

He acquired a great reputation as a lawyer, less by practice in the courts than in a consultative capacity. He strenuously opposed the "parlement Maupeou," devised by the Chancellor Maupeou to replace the old judiciary bodies, and refused to plead before it. He was counsel for the cardinal de Rohan in the affair of the Diamond Necklace (*q.v.*). In 1785 he was elected to the French Academy. In 1789 he was returned as one of the deputies of the Third Estate in Paris to the states-general, where he supported all such revolutionary measures as the union of the orders, the suspensive veto, the civil constitution of the clergy, &c. His excessive obesity, which in the Constituent Assembly made him the butt of the Royalists, had prevented him from practising at the bar for some years before 1789, and when Louis XVI. invited him to undertake his defence he excused himself on this ground. At the same time he published in 1792 some *Observations* in extenuation of the action of the king, from the constitutional point of view, which in the circumstances of the time argued much courage. For the rest, he took no part in public affairs during the Terror. Under the Directory he was made a member of the Institute (1796) and of the Court of Cassation (1798). He lived to collaborate in the earlier stages of the new criminal code. Among his writings may be mentioned a paper on the grain trade (1776) and a *Mémoire sur l'état des Protestants en France* (1787), in which he pleaded for the restoration of civil rights to the Protestants.

See Victor du Bled, "Les avocats et l'Académie Française," in the *Grand Revue* (vol. ii. 1899); H. Moulin, *Le Palais à l'Académie: Target et son fauteuil* (Paris, 1884); P. Boulloche, *Un avocat au 18ème siècle* (Paris, 1893).

TARGET, a mark to shoot at, so called from its resemblance in shape to the "targe" or small round shield, particularly the round wood and leather buckler, with metal bosses, and long spike protruding from the central boss, which was carried by the Highland clans; at the back was a leathern sleeve in which the left arm was inserted. In the 17th century, as body armour ceased to be used, the infantry soldier often carried a light shield of various forms which was known as a "target," which is a diminutive of targe; such soldiers were known as "targeteers." "Targe" is a word that has been the subject of much etymological discussion. On the one hand is found the O.E. *targe*, with hard *g*, a shield, cf. Icel. *targa*, shield, target, and O.H. Ger. *zarga*, frame, side, border; on the other is Fr. *targe*, Sp. and Port. *tarja*, Ital. *targa*, buckler, shield. The soft and hard *g*'s point to two distinct words. In Sp. and Port., is found *adarga*, a square target or buckler, which is an Arabic word, *al darkat* or *darakat*, a leather shield. The O.E. and Icel. words can hardly have come from an Arab. source, and the relation between the two words is an etymological puzzle (see Skeat, *Etym. Dict.*, 1910). The target as a mark to shoot at is, for archery, a circular canvas-covered frame stuffed with straw and marked with concentric rings surrounding the centre or bull's-eye. For shooting with the rifle the target is usually square.

In the days of the smooth-bore musket, and for many years after the introduction of small arms of precision, the targets used in musketry training were of a "match" and not a "service" character. The target was white with a black bull's-eye (counting 5 points) and two rings, invisible to the firer, called the "inner" and the "magpie," and scoring 4 and 3; the rest of the target was called the "outer" and counted 2 points. This system was the basis of all match shooting, whether with match or service rifles, and (with the trifling difference that the bull counted 4, the inner 3 and the magpie and outer alike 2) it was followed in military range practice. For collective fire regular rows of black silhouettes on white screens were employed. These were a compromise between bull's-eye and service targets which possessed the virtues of neither. But after the S. African war bull's-eye practices were eliminated from the musketry course of the British army, and in the musketry regulations of 1909 they were restricted to the earliest stages of recruits' training and trained soldiers' "refresher" courses. The use of the bull's-eye to-day is to teach the soldier to shoot uniformly, that is, to "group" his shots closely. The position of his shot group with reference to the bull's-eye does not matter; if his group is comprised within a 6 or 12-inch ring (at 100 yards range) he is passed on to more advanced practices at service targets. The latter are no longer coloured black-and-white, but are of the dull colours which are met with in the field, either brown head-and-shoulders painted on a green-grey canvas background or brown silhouettes held up against the face of the stop-butt. The National Rifle Association in 1910 followed the lead of the War Office to some extent as regards the targets used at the Bisley meeting in "service-rifle" competitions. For collective practices at the more important military stations large areas of ground are prepared with silhouettes in entrenchments, dummy guns, &c. Mechanical "running-man" and "disappearing" targets are also used for training in snap-shooting and rapid fire. The target used in naval gunnery is a large floating frame of timber either fixed by buoys or anchors or towed at a distance by a vessel (see ORDNANCE: § *Naval Gunnery*).

TARGUM. The Targums are the Aramaic translations—or rather paraphrases—of the books of the Old Testament, and, in their earliest form, date from the time when Aramaic superseded Hebrew as the *spoken* language of the Jews (see HEBREW LANGUAGE). In their origin they were designed to meet the needs of the unlearned among the people who had ceased to understand the Hebrew of the Old Testament. In the absence of any precise evidence on the point it is impossible to give more than a rough estimate as to the period at which Hebrew, as a spoken language, was finally displaced by Aramaic. It is, however, certain that the latter language was firmly established in Palestine in the 1st century A.D. By that time, as we know from many sources, Aramaic was not only the language in common use, but had also received official recognition,[1] despite the fact that Hebrew still remained the learned and sacred tongue. Hence we may reasonably infer that the mass of the people had adopted Aramaic at a considerably earlier period, probably, as early as the 2nd century B.C., and that the need of Aramaic translations of the sacred text made itself felt but little later. By the Jews[2] the introduction of Targums is ascribed to Ezra; but this tradition, which probably owes its origin to the Talmudic explanation of Neh. viii. 8,[3] is inconsistent with the linguistic evidence furnished by the post-exilic literature of the Old Testament, and must be rejected as unhistorical, if only because the process by which Aramaic took the place of Hebrew was admittedly a very gradual one. The Talmudic tradition, however, is, doubtless, correct in connecting the origin of Targums with the custom of reading sections from the Law at the weekly services in the synagogues, since the need for a translation into the vernacular must first have arisen on such occasions. As we know from the New Testament, the custom of reading in the synagogues both from the Law[4] and from the Prophets[5] was well established in the 1st century A.D.: its introduction, therefore, will date from a much earlier period. The practice of accompanying these readings with a translation into Aramaic is, further, so generally recognized by the 2nd century A.D. that the Mishna[6] takes it for granted, and merely inculcates certain regulations to be observed by the *Meturgemān* (translator), who had by this time acquired a definite status. From it we learn that the *Meturgemān*, who was distinct from the reader, translated each verse of the Law into Aramaic as soon as it had been read in Hebrew: in the readings from "the Prophets" three verses might be read at a time. Later regulations are also laid down in the Talmuds in order to prevent any appearance of authority attaching to the translation, and also to ensure reverential

treatment on the part of the translator.[1] Elsewhere,[2] we only find references to certain passages of Scripture, viz., the stories of Reuben and Tamar (Gen. xxxv. 22 and xxxviii.), the two accounts of the golden calf (Exod. xxxii.), the blessing of the priests (Num. vi. 22 f.), the stories of David and Amnon (2 Sam. xi., xii. and xiii.), which might be either read and translated, or only read and not translated, or (according to a different tradition) neither read nor translated. It is noticeable that none of the passages cited conveys any rules or information as to the character of the translation to be employed. Judging by the contents of our existing Targums, and the Targumic renderings given in Jewish literature, it is improbable that any definite system of interpretation was ever formally adopted, the rendering into the vernacular being left to the discretion of the individual *Meturgemān*. At first, no doubt, the translator endeavoured to reproduce the original as closely as possible, but, inasmuch as his object was to give an intelligible rendering, a merely literal rendering would soon be found to be insufficient, and he would be forced, especially in the more difficult passages, to take a more elastic view of his obligations. To prevent misconception he must expand and explain what was obscure, adjust the incidents of the past to the ideas of later times, emphasize the moral lessons to be learned from the national history, and, finally, adapt the rules and regulations of the Old Covenant to the conditions and requirements of his own age. As time went on the practice of introducing additional matter of an edifying character grew in popular favour, and was gradually extended. Thus, by degrees, the reproduction of the original text became of secondary importance, and merely served as a pretext for the discussion of topics that had little or no bearing on the context. The method, by which the text was thus utilized as a vehicle for conveying homiletic discourses, traditional sayings, legends and allegories, is abundantly illustrated by the Palestinian and later Targums, as opposed to the more sober translations of Onkelos and the Targum to the Prophets.

It would, however, be incorrect to suppose that the translation of the text was left entirely to the individual taste of the translator. The latter is rather to be regarded as the representative of the age in which he lived, and his interpretation is to be taken as reflecting the exegesis of that period. That there were certain limits beyond which the translator might not venture, without incurring the censure of the authorities, may be inferred from the few instances of translation which are mentioned with disapproval in the Mishna and elsewhere. Thus the rendering of Lev. xviii. 21 [a] by "Thou shalt not give any of thy seed to an Aramean woman to make her conceive" is censured, presumably because the prohibition of Molech worship is thereby ignored.[3] In the same Mishnic passage it is forbidden to render Lev. xviii. 7 as if the text had "*his* father" and "*his* mother."[4] Yet another translation (that of Lev. xxii. 28) is mentioned with disapproval in the Jerusalem Talmud,[5] though it has been preserved in the Targum Pseudo-Jonathan *ad loc.*[6] A definite rule for guidance in translating is apparently preserved in the *Tosefta*,[7] where it is stated that "he who translates quite literally is a liar, while he who adds anything is a blasphemer," Exod. xxiv. 10, "and they saw the God of Israel" is cited as an example. It is argued that the literal rendering of this passage is inadmissible, because no man has ever seen God; on the other hand, the insertion of the word "angel" before God would be blasphemous. The correct rendering is stated to be "and they saw the glory of God." But it is doubtful if the rule here given was ever intended to apply to more than the particular type of passage exemplified: if it had been applied generally, it would have clashed with the whole trend of Midrashic and Targumic paraphrase.

There can be little doubt that the Targums existed for a long time in oral form. They belonged to the class of traditional literature which it was forbidden to write down, and, so long at least as the Targum tradition remained active, there would be little temptation to commit it to writing. But it is highly probable that this prohibition, in the case of the Targums, was mainly enforced with respect to those parts of the Old Testament which were read in the synagogal services, *e.g.* the Law and the Prophets, and that it was less rigidly observed in regard to the other portions of Scripture: a written translation of the latter would be of special value for the purpose of private study. Hence there is no need to reject the tradition as to the existence of a written Targum on Job in the time of Gamaliel I.[8] (1st century A.D.), especially as references to Targum MSS. occur in the Mishna and elsewhere.[9] But, as Dalman has pointed out,[10] it was not these manuscripts, but the living tradition of the learned which was recognized as authoritative throughout the period which closes with the compilation of the Talmud. . . . The official recognition of a written Targum, and therefore the final fixing of its text belongs to the post-Talmudic period, and is not to be placed earlier than the 5th century.

I. Targums on the Pentateuch

(1) The so-called Targum of Onkelos admittedly owes its name to a mistaken reference in the Babylonian Talmud.[11] In its original context, that of the Jerusalem Talmud,[12] the passage refers to the Greek translation of Aquila. With the exception of this one reference, the Targum is always introduced in the Babylonian Talmud by the phrase "as we translate" (כדמתרגמינן), or "our Targum" (תרגום דידן): it is probable, therefore, that the name of the author, or authors, was unknown to the Babylonian Jews. It is first quoted under the title of the Targum of Onkelos by Gaon Sar Shalom (d. A.D. 859). According to Dalman,[13] its language differs in many material particulars from the Aramaic dialects of the Palestinian and Babylonian Talmuds, and is more closely allied to the biblical Aramaic. On the linguistic side, therefore, we may regard Onkelos "as a faithful representative of a Targum which had its rise in Judaea, the old seat of Palestinian literary activity." It is not, however, to be regarded as a reproduction in written form of a Palestinian translation, but rather as an official translation of the Law, in the Judaean dialect, which was carried out in Babylon, probably about the 4th century A.D.: in its final form, according to Dalman (*l.c.*) it cannot be earlier than the 5th century. The translation, as a whole, is good, and adheres very closely to the Hebrew text, which has not been without its influence on the Aramaic idiom; at times, especially in the poetical passages, a freer and more paraphrastic method is employed, and the version shows evident traces of Halakhic and Haggadic expansion. The Hebrew text used by the translators appears to have been practically identical with the Massoretic. The version was held in high esteem in Babylon, and, later, in Palestine, and a special Massora was made for it. The latest edition is Berliner's reprint (1884) of the *Editio Sabbioneta* (1557).

Of all the extant Targums that of Onkelos affords perhaps the most characteristic and consistent example of the exegetical methods employed in these works. Two principles may be said to have guided the translators. On the one hand, they had, as their primary object, to produce a faithful rendering of the original which at the same time would be intelligible to the people: for this purpose a purely literal translation would be insufficient. On the other hand, they regarded it as necessary to present the sacred text in such a manner as best to convey the particular form of interpretation then current. But later Jewish exegesis was especially concerned to eliminate everything in the sacred writings that might give rise to misconception with respect to God on the part of the unlearned. Hence we find various expedients adopted in the Targums for avoiding any reference to the Deity, which might be misunderstood by the people, or which involved apparent irreverence. Examples of this peculiarly Targumic method are: (1) the insertion of "word" (מימרא), "glory" (יקרא), "presence" (שכינא) before the divine name, when God is referred to in his

dealings with men; (2) the insertion of the preposition "before" (קדם) when God is the object of any action; (3) the use of the passive for the active voice, *e.g.* גלי קדם for ידע or ראה; שמיע ק״ for שמע; אתגלי for עבר, יצא, ירד, בוא; דכיר for זכר; (4) the use of periphrasis for the more pronounced anthropomorphisms, such as "to smell," "to taste," or when the use of the *status constructus* might seem to bring God into too close connexion with men or things; (5) the use of different expressions, or the insertion of a preposition before the divine name, when God is compared to man, or the same action is predicated of God and man; (6) the use of ״ for יהוה and אלהים, and the rendering דחלא or טעוא when אלהים denotes heathen gods. Instances of this endeavour to maintain, as it were, a respectful distance in speaking of God occur on every page of the Targums, but cases also occur, by no means infrequently, where human actions and passions are ascribed to God. The explanation of this phenomenon is to be found in the fact that anthropomorphisms, as such, were not necessarily avoided, but only in those cases where they might be misunderstood by the people.

(2) In addition to the Targum of Onkelos two other Targums to the Pentateuch are cited by Jewish authorities, under the titles of the *Targum Jerushalmi* and the Targum of Jonathan ben Uzziel. Of these the former contains only portions of the Pentateuch,[1] and is therefore usually designated the Fragmentary (Jerusalem) Targum. In a large number of cases this Targum gives merely a variant rendering of single words: where longer passages are given it presents a very paraphrastic translation, and bears all the marks of a late Haggadic composition. Its fragmentary character arises from the fact that it is simply a collection of *variae lectiones* and additions to the version of Onkelos, intended possibly for use at public services.[2] That this Targum was really intended to supplement that of Onkelos is shown by comparing the two texts. For the former is frequently unintelligible without the latter, since it offers no translation of those words, or clauses, for which it gave the same rendering as Onkelos. On the other hand, the version of Onkelos affords just the supplementary material that is required to restore sense to the shorter text. Moreover, in not a few cases the Fragmentary Targum itself attaches to its variant rendering the succeeding word from Onkelos, thus indicating that from this point onwards the latter version is to be followed. More conclusive still is the fact that in a number of old *Maḥzor* MSS. we find Targums to the Song of Moses and to the Decalogue, in which this process has been fully carried out, the text of Onkelos being given as well as the variants of the Fragmentary Targum.

The second Jerusalem Targum, or the so-called pseudo-Jonathan, admittedly owes its ascription to Jonathan ben Uzziel to the incorrect solution of the abbreviated form by which it was frequently cited, viz. ת״י, or *Targum Jerushalmi* (תרגום ירושלמי). This Targum represents a later and more successful attempt to correct and supplement the Targum of Onkelos by the aid of variants derived from another source. It is not, however, a revision of the Fragmentary Targum—for it is clearly independent of that version—but is rather a parallel, if somewhat later, production, in which the text of Onkelos is already combined with a number of variants and additions. It is noticeable that this Targum has been considerably influenced by the Targum of Onkelos, and in this respect, as in others, is far less trustworthy than the Fragmentary Targum, as a witness to the linguistic and other peculiarities of the source from which they were both derived. It exhibits, to a marked degree, that tendency to expand the text by additions of every kind, which has been already noted as characteristic of the later stages of Targumic composition. Homilies, legends, traditional sayings and explanations, in fact every form of Haggadic expansion are utilized by the Targumist, so that at times his works convey the impression more of a late *Midrash* than of a translation. This impression is fully confirmed by (*a*) a comparison of the Talmud and later Midrashic works with which it has obvious points of contact, and (*b*) the historical allusions, such as the mention of Constantinople (Num. xxiv. 19), of a wife and daughter of Mahomet (Gen. xxi. 21), and the references to Esau and Ishmael as representative world-powers (Gen. xlix. 26; Deut. xxxiii. 2; cf. Fragm. Tg. to Gen. xlix. 2; Deut. xxxiii. 2).[3] In its translation of the Hebrew pseudo-Jonathan is careful to avoid anthropomorphisms and to give the sense of all but the most simple metaphors, though his method is not so thorough as that of Onkelos. Every endeavour is made to gloss over, or modify, expressions which seemed derogatory to the ancestors of Israel, and to amplify everything which redounded to their credit. On the other hand, pseudo-Jonathan shows a tendency to condense those additions which it has in common with the Fragmentary Targum: in particular he omits all quotations from Scripture.

In regard to the source of the two Palestinian Targums to the Pentateuch, we must accept the conclusion of Bassfreund[4] that they both derived their variants from a complete *Targum Jerushalmi.* This conclusion is based on the following grounds: (1) Various Jewish works dating from the 11th to the 14th century contain a large number of quotations under the heading ת״י, *i.e. Targum Jerushalmi.* Of these rather less than a quarter are found in the Fragmentary Targum, the remainder being mostly taken from passages for which no translation of that Targum exists. This completer work, however, cannot be identified with the pseudo-Jonathan, for more than half of these quotations are missing from the latter; and further, in passages for which we possess both the Targums, the text of the Fragmentary Targum agrees much more closely with the quotations: the linguistic evidence also shows that the Fragmentary Targum is a more faithful representative of the original source; (2) the pseudo-Jonathan displays a curious inconsistency in its rendering of particular words and phrases, at one time following Onkelos, at another a different source. That this latter source is the *Targum Jerushalmi* is proved, in the majority of cases, by a comparison with the Fragmentary Targum; (3) quotations from Scripture preserved in the Fragmentary Targum point to a completer version than our present Fragmentary Targum. But though the existence of an older *Targum Jerushalmi* cannot be denied, it is clear that the form in which it was utilized by the two Palestinian Targums cannot be of an early date, for many of the latest elements in the Fragmentary and pseudo-Jonathan Targums were undoubtedly derived from their common source. Moreover, the existence of a written Palestinian Targum at an early date is expressly excluded by the evidence at our disposal. In the middle of the 2nd century A.D. R. Simon ben Gamaliel forbade the translation of the Pentateuch in any language but Greek;[5] and this command was upheld by R. Johanan in the 3rd century. Even in the time of the later Amoraim there is no mention of a written Palestinian Targum, though the official Babylonian Targum is repeatedly referred to in the Babylonian Talmud, in the Midrashim, and at times also by Palestinian Amoraim. These considerations are sufficient to disprove the theory of Geiger,[6] which has for so long been accepted in one form or another, that the Targum of Onkelos was merely a reproduction of the old *Targum Jerushalmi* revised in accordance with the "new Halakha" introduced by R. Aqiba. Yet it is impossible to hold that the Targum of Onkelos was the only representative of Targum tradition that existed among the Jews down to the 7th century A.D., the period to which the internal evidence compels us to assign the *Targum Jerushalmi* as used by the Fragmentary Targum and the pseudo-Jonathan. We must rather assume that a tolerably fixed Targum tradition existed in Palestine from quite early times. The language employed in the Targum of Onkelos is, admittedly, Palestinian or Judaean, and since language and thought are ever closely allied, we may conjecture that the current Judaean exegesis, which, in part at least, must go back to the 2nd century A.D., was not without its influence on the Babylonian translation. This old Targum tradition, however, never received official recognition in Palestine, and was unable, therefore, to hold its own when the new Babylonian version was introduced. We may infer that, as time went on, a reaction in favour of the older renderings made itself felt, with the result that these were collected in the form of variants and appended to Onkelos. But the authority enjoyed by the latter rendered it secure against any encroachments; hence any later expansions, especially those of a popular Haggadic character, naturally found their way into the less stereotyped *Targum Jerushalmi.* Unfortunately, we possess but little material for controlling the texts either of the Fragmentary Targum or of the pseudo-Jonathan. Of the latter only one manuscript (Brit. Museum Add. 27031) is known to exist, and this has been utilized by Ginsburger in his *Pseudo-Jonathan* (Berlin, 1903). The same scholar has also edited the Paris manuscript (110) of the Fragmentary Targum (*Das Fragmententhargum*, Berlin, 1899), to which he has added the variants from Cod. Vat. 440 and the manuscripts at Nuremberg and Leipzig. In the same edition are collected the various fragments of the *Targum Jerushalmi*, which are to be found in the early editions of the Pentateuch and in part also in various manuscripts.

II. Targums on the Prophets

The official Targum on the Prophets is stated by the Babylonian Talmud[7] to have been "said" by Jonathan ben Uzziel, the disciple of Hillel, and is usually known, therefore, as the *Targum Jonathan.* Elsewhere in the Talmud, however, the quotations from this Targum are given under the name of Joseph bar Chijah, head of

[1] According to Zunz, *Gottesdienstliche Vorträge*, 2nd ed., p. 80, its contents bear the following proportions:—$\frac{1}{3}$ to Genesis, $\frac{3}{20}$ to Exodus, about $\frac{1}{14}$ to Leviticus, $\frac{1}{5}$ to Numbers, and $\frac{1}{4}$ to Deuteronomy.

[2] Seligsohn, *De duabus Hier. Pent. paraphrasibus* (1858): for a fuller discussion see Bassfreund, "Das Fragmenten Targum" in *M.G.W.J.* xl.

[3] The view that Deut. xxxiii. 11 could only have been written by a contemporary of John Hyrcanus cannot be maintained; cf. Dalman, *Gramm.* p. 30 f., and, more fully, Bassfreund, *M.G.W.J.* xliv. (1900), pp. 481 f.

[7] *Meg.* 3*a*.

the school at Pumbadita in the 4th century A.D. Both in language—though naturally there is some variation of vocabulary—and style it closely resembles the Targum of Onkelos, and appears to have been modelled on that translation: in certain passages, indeed, it appears to have made use of it.[1] Probably, like Onkelos, it did not assume its final form in Babylon before the 5th century A.D. It naturally follows from the character of the original that the rendering of this Targum is less literal than that of Onkelos, especially in the prophetic books, but, when due allowance is made for the difficulty of the Hebrew, it may be described on the whole as a faithful reproduction of the original text. Its peculiarities of rendering are due to the same principles which were noted as underlying the translation of the Pentateuch. Anthropomorphisms, as a rule, are avoided by means of the same expedients as those employed by Onkelos, expressions derogatory to the dignity of God, or of the heroes of the nation, are softened down, while figurative language is either boldly transposed, or its character clearly shown by the introduction of the particle "as" or "like." There is, further, a tendency to narrow down the scope of the prophetic utterances, and to limit their application to Israel and its immediate enemies. Lastly, in the obscurer passages the Haggadic method of interpretation is employed to its fullest extent, while the translation throughout shows a marked tendency to explanatory additions.

Of a *Targum Jerushalmi* to the Prophets but little is known, though it is hardly doubtful that such a Targum existed, if only in oral form. Traces of this version have been discovered by Bacher[2] in the variants attached to the margin of the *Codex Reuchlinianus*, and printed by Lagarde in his edition of *Prophetae Chaldaice* (1872). These fragments, which have been preserved under the headings ירוש, יו״ר, תרג״ יר״, exhibit certain features in common with the Jerusalem Targums to the Pentateuch, and are demonstrably of post-Talmudic date. According to Kohut's list of Targum quotations in *'Arūk*, a Jerusalem Targum existed also for the Psalms, Proverbs, Job, Canticles, Lamentations, Ecclesiastes and Esther, but this list is scarcely reliable, and, as Dalman has pointed out,[3] the quotations in *'Arūk* to Kings, Ezekiel, Proverbs and Lamentations are the only ones that point with certainty to the existence of a *Targum Jerushalmi*.

III. Targums to the Hagiographa

These Targums possess but little interest for the student of Jewish literature as they are almost entirely the work of individuals, made in imitation of the older Targums. Despite the reference to a Targum of Job in the 1st century (see above), all the extant Targums to the Hagiographa are later in date than the Targums to the Law and the Prophets.

(1) *Targums to the Psalms and Job.*—These Targums present certain features in common and may therefore be treated under the same heading. Like all the later Targums they exhibit a large amount of explanatory addition, chiefly Haggadic in character. At the same time the translation of the original is not neglected; and, when separated from the later accretions, this is found to follow the Hebrew tolerably closely. Peculiar to these Targums are the double translations, which they give to many verses, one of which is usually Haggadic in character, while the other is more literal. Bacher[4] would assign these Targums to the 4th or 5th century, but, as Dalman has pointed out,[5] they exhibit linguistic features in common with the Jerusalem Targums to the Pentateuch. They cannot be earlier than the 7th century A.D., and possibly are of a considerably later date.

(2) *The Targum to the Proverbs* stands apart owing to the peculiarity of the language in which it is written. The influence of the Peshitta version is so clearly marked,[6] that Dalmân (*l.c.*) describes it as a Jewish revision of that version. But setting aside the Syriasms due to the use of the Peshitta, the Targum shows affinity to the Targums to the Psalms and Job. The translation is literal and almost entirely free from Haggadic additions.[7]

(3) *The Targums to the Megilloth.*—The chief characteristic of these Targums is their exaggerated use of paraphrase. They mark the final stage in the development of Haggadic interpretation, in which the translation of the text has practically disappeared in a mass of fantastic and irrelevant matter. The Targum of Esther is known to us in three recensions (1) that of the Antwerp Polyglot, almost a literal translation; (2) that of the London Polyglot, which gives practically the same text with many additions of a Haggadic character; (3) the so-called second (*shēni*) Targum, a much larger work, containing a collection of later *Midrashim* to this book. According to Zunz[8] this "second" Targum is quoted by Rashi (to Deut. iii. 4) as a Jerusalem Targum, and also (1 Kings x. 19) as the "Haggada" of the Megilloth Esther. The Targum to Canticles is of a similar character to that of the "second" Esther. Dalman assigns these Targums to a date half-way between the Babylonian Targums (Onkelos and that to the Prophets) and the Jerusalem Targums to the Pentateuch and those to the greater Hagiographa. The British Museum possesses three important Yemen manuscripts for the five Megilloth and the "second" Esther Targum in MSS. Or. 1302, 1476, and 2375.

(4) *The Targum to the Chronicles* was first edited from an Erfurt manuscript by M. F. Beck, 1680–1683. A more complete and accurate edition from a Cambridge manuscript was edited by D. Wilkins in 1715. In the translation, which at times is fairly literal, use appears to have been made of the Jerusalem Targums to the Pentateuch, and of the Targums to the books of Samuel and Kings. The text represented by the Erfurt manuscript is assigned to the 8th, that of the Cambridge manuscript to the 9th century A.D.[9]

No Targums have so far been discovered to Daniel and 'Ezra and Nehemiah. (J. F. St.)

TARIFA, a seaport of Spain, in the province of Cadiz, at the extreme south point of the Peninsula, 21 m. by rail W.S.W. of Gibraltar. Pop. (1900) 11,723. The town is nearly quadrangular, with narrow, crooked streets, and is still surrounded by its old Moorish walls. On its east side, just within these, stands the citadel. The rocky island in front of the town, connected with the mainland by a causeway, is strongly fortified; on the south side there is a modern lighthouse. Anchovy and tunny fishing is carried on, and there is some coasting trade, chiefly in live stock, salt fish and fruit. The manufactures (leather and earthenware) are unimportant. The oranges of Tarifa are famed for their sweetness.

Tarifa is the *Julia Joza* of Strabo, between Gades and Belon. According to that writer, it was colonized by Romans and the removed inhabitants of Zelis in Mauretania Tingitana. The *Julia Transducta* or *Traducta* of coins and of Ptolemy appears to be the same place. Its present name, dating from early in the 8th century, is derived from Tarif, whom Ṭāriq sent to Spain in command of the advance-guard of the Moorish invaders (see Caliphate and Spain: *History*). In 1292 Tarifa was taken by Sancho IV. of Castile from the Moors, who made several subsequent attempts to recapture it. In the defence of Tarifa Alphonso XI. gained the battle of Salado, a short distance to the westward, in 1340. In 1812 a French force of 10,000 men under Generals Victor and Laval vainly endeavoured to capture Tarifa, which was garrisoned by 2500 troops (mostly British) under General Gough.

TARIFF (adapted in English from the French; the word comes through the Spanish *tarifa*, a list or schedule of prices, from the Arabic, *ta'rifa*, information, an inventory, *'arf*, knowledge), a table or list of articles on which import or export duties are levied, with the amount of the duty specified, hence often used as a collective term for the duties imposed, or for the law or code of regulations imposing such duties or varying the scale of charges. The word is also used quite widely of any schedule of prices or charges, and, particularly in America, of the freight or other charges of a railway or steamship line.

Resort is made to tariffs, or duties on imports, partly to secure revenue, partly to affect the course of industry within a country. Strictly speaking, these two objects are inconsistent with each other; since a customs duty, in so far as it causes a domestic industry rather than a foreign to supply the market, ceases to be a source of revenue. But in a great number of cases the imposition of a duty causes only a partial displacement of the foreign supply, and hence brings some revenue from that which remains. This circumstance strengthens the hold of the protective system, especially in countries where customs duties are an important source of revenue, the combination of fiscal convenience and of protection to home industry being a highly attractive one. Where tariff duties are imposed solely for revenue, an equivalent excise tax is imposed within the country, so as to put the domestic producer precisely on the footing of his foreign competitor; and tariffs so maintained are in complete conformity with the principle of free trade.

Great Britain.—Between the close of the Napoleonic wars of 1815 and the year 1860, the tariff system of Great Britain was changed from elaborate protection to practically complete free trade. An attempt had indeed been made in 1786 to modify the rigidly protective legislation of the 18th century. In that year Pitt concluded a commercial treaty with France, providing for large reductions of duties in both countries. But the treaty was swept away with the outbreak of the wars with France, and accordingly the old system was still in force in 1815. The first important step, and in some respects the decisive step, towards modifying it was taken in 1824, under the policy of Huskisson. In that year, and again in 1825, great reductions were made in the duties on raw materials, especially on wool, raw silk, flax and iron, while considerable reductions were also made in the duties on manufactured goods. The most sharply contested of the changes was in regard to silks, which had been completely prohibited, and were now admitted at a duty of 30 per cent. A considerable breach was thus made in the protective system; and some further changes in the same direction were made in the next decade, especially under Lord Althorp in 1833. But in the decade from 1830 to 1840 the Corn Laws were the chief subject of contention. The great increase in population since the middle of the 18th century had made England a corn-importing country, especially with the rapid growth of manufactures in the early years of the 19th century. The first systematic Corn Laws imposing duties on grain had been passed in 1773. From 1861 onwards a series of measures were passed, all designed to maintain the high price of grain. The Act of 1816 prohibited the importation of wheat when the price was less than 80s. a quarter (=$2.50 a bushel). In 1822 the prohibitive point was lowered to 70s. In 1828 the sliding scale was introduced, under which the duty went up and down as the price of grain went down and up; and it was against this form of the Corn Law that the great agitation led by Cobden and Bright was directed after 1830. For a long time the anti-Corn Law agitation seemed to have no effect, although conducted with extraordinary skill and enthusiasm. In 1842, however, Sir Robert Peel made the first important concession, by modifying the sliding scale, his opponent, Lord John Russell, having proposed in the previous year a fixed duty of 8s. a quarter. In view of the bad harvest of 1845–46, and the famine in Ireland in 1846, Peel surrendered, and proposed in 1846 the admission of grain with only a fixed duty of 1s. a quarter as a registration fee. This change was carried, but Peel, being able to carry only a fraction of his party with him, was compelled shortly afterwards to resign. The Corn Laws had great political strength, serving as they did the interests of the landowners, whose hold on parliament was still very strong; but the general economic situation in Great Britain, from the rapid growth of the manufacturing population and the imperative need of more food, made the abolition inevitable. After having been maintained till the middle of the century, apparently with irresistible support, they suddenly collapsed under the strain of a season of exceptionally short crops. Both their continued maintenance and their final sudden abolition are in some respects divergent from the general course of British tariff history.

Corn Laws repealed, 1846.

The remodelling of the tariff system in the direction of free trade went on, little retarded by the maintenance of the Corn Laws and not much accelerated by their abolition. In 1842 great reductions of duty were made on a large number of articles; in 1846 still further reductions of duty were made; another series of changes came in 1853; and finally, in 1860, the last remnant of protective duties disappeared. The four acts of 1842, 1846, 1853, 1860—the first two under Peel's leadership, the second two under Gladstone's guidance—thus carried out gradually the policy of free trade in regard to other articles than grain. The first of them, in 1842, was signalized by the introduction of the Income Tax as a means of raising revenue to replace that lost by the diminished import duties. The last of them, in 1860, was largely influenced by the great commercial treaty with France. In that treaty the concessions made to France were the reduction by Great Britain of duties on wines and spirits, and the admission, free of duty, of some important French products, notably silk manufactures, gloves, and other products in which the French had superiority. Great Britain, instead of limiting the concessions to France, in 1860 made them applicable to all the world. The silk manufacture, as to which the first great changes had been made in 1824, and on whose products the duties had been kept higher in previous acts than on other manufactures, was thus compelled, notwithstanding violent opposition, to face unfettered foreign competition.

General changes in 1842–60.

Two general features should be noted in regard to the tariff history of Great Britain. In the first place, most of the reductions of duty on manufactured articles were of little practical significance. The great mass of manufactured commodities were produced in the United Kingdom more cheaply than in foreign countries, and would not have been imported, with duty or without, except in sporadic amounts for some special qualities. The changes hence involved little real readjustment of industry. There is thus some ground for the assertion that the policy of free trade was not adopted by the United Kingdom until its industries had reached the stage of being independent of protection. But this does not hold good of some manufactures; especially not of the silk industry, and some parts of the woollen and linen trades. Still less does it hold good of raw materials, many of which had been really affected by the duties, and were largely imported after their abolition. Such was the case not only with some metals, such as lead, zinc, copper, but still more strikingly with textile materials such as wool, flax, and the like, and most of all with agricultural products such as grain, meat and meat products, timber. In regard to all these, the abolition of protection meant a real sacrifice to domestic industries. The second feature to be noted is the simplification which resulted in the administrative features of the English tariff. A great number of articles had been enumerated in the earlier tariff acts, each of which was imported in very small quantity and yielded an insignificant revenue. The nature of the changes made between 1842 and 1860 is indicated by the following tabular statement:—

	Duties reduced.	Duties abolished.
1842–46	503	390
1846	112	54
1853	...	123
1860	...	371

After 1860 only forty-eight articles remained subject to duty, a number which has been still further reduced, the most notable change having been free admission of sugar in 1872. Since that date the English customs tariff has been simplicity itself. A very few articles (spirits, beer, wine, tobacco, tea, coffee, cocoa) yield practically all of the customs revenue, and, so far as these articles are produced within the country, they are subject to an excise duty, an internal tax precisely equal to the import duty. In 1901, to aid in meeting the expenses of the South African war, a moderate revenue duty was again imposed on sugar; and in 1902 the shilling duty on corn and flour (abolished in 1869) was restored, but again taken off in 1903. In this year began the "Tariff Reform" movement initiated by Mr Joseph Chamberlain (*q.v.*), but Free Trade retained a strong hold on the British electorate, and the return of the overwhelming Radical majority to parliament in 1906 involved its retention under the fiscal policy of that party. In January 1910 the Liberal government was again returned to power; but the Unionist party was now committed to Tariff Reform, which had made great strides in obtaining popular support.

France.—The tariff history of France in the 19th century divides itself into three periods: one of complete prohibition, lasting till 1860; second, of liberal legislation, from 1860 to 1881; third, of reversion to protection after 1881.

(1) During the first period the prohibitive legislation of the 18th century was retained, largely in consequence of the Napoleonic wars. The commercial treaty of 1786 between Great Britain and France has already been referred to as making a breach in the restrictive system of the 18th century; and in the early years of the French Revolution a similar wave of liberal policy is to be seen. But the great wars led to the complete prohibition of the importation of manufactures, reaching its climax in Napoleon's Continental system. The system of prohibition thus instituted, while aimed at Great Britain, was made general in its terms. Hence the importation into France of virtually all manufactured articles from foreign countries was completely interdicted; and such was the legislation in force when peace came in 1815. This system doubtless was not expected to last after the wars had ceased, but, as it happened, it did last until 1860. Successive governments in France made endeavours to break with the prohibitive system, but naturally met with strong opposition from the manufacturing interests, not prepared to meet the competition of Great Britain, whose industries had made, and were continually making, rapid strides. The political position of the governments of the Restoration and of Louis Philippe was such that they were unwilling to forfeit support by pushing measures in which, after all, they were not themselves deeply interested.

Treaty of 1860.

(2) It was not until Napoleon III. believed it to be to his political advantage to strengthen friendly relations with Great Britain by the moderation of the import duties that the change was finally made; while the despotic character of his government enabled him, when once the new policy was entered on, to bring about a radical change. After some secret negotiations, in which the English Corn Law agitator, Cobden, and the French economist, Cherbuliez, took an active part, Napoleon was persuaded to enter on the famous commercial treaty of 1860, and virtually to force its acceptance by the French legislature. In the treaty as finally framed duties on most manufactured commodities were reduced to a range of 10 or 15 per cent., some iron manufactures, however, being left at slightly higher rates. Before the treaty, all woollen and cotton manufactures, all manufactures of leather, of hardware, pottery, all glass ware, had been prohibited, while raw materials and such manufactures as were not prohibited had been subjected to heavy duties. The treaty thus made a radical change, revolutionizing the tariff system of France. It did so with relation not only to the United Kingdom, but, in its after effects, to the world at large. The French government at once set to work to enter into similar arrangements with other countries, and treaties were successively concluded in 1860–66 with Belgium, with the Zollverein (Germany), Italy, Switzerland, Sweden and Norway, Holland, Spain, Austria. All these countries made reductions of duty on French products, while France admitted other products at the rates of the British treaty tariff. Thus a network of treaties was spread over Europe, leading to much great freedom of trade and opening an era of freer international exchange.

Reaction since 1880.

(3) This more liberal policy, however, probably never had deep root in French public opinion. It received a check from the Franco-German War of 1870–71. The treaty of Frankfort in 1871 contained, in place of the previous detailed commercial treaty with Germany, the simple "most favoured nation" proviso. The guarantee which each country thus gave to the other of treatment as favourable as that given elsewhere became irksome to France, sore after her defeat in the war. More important, however, in undermining the liberal system, was the change in agricultural conditions which began to set in in the decade of 1878–88. Then the great improvements in transportation caused competition in agricultural products to be felt, especially from the United States. Agricultural prices declined; agricultural depression set in. The agricultural interest in France, hitherto indifferent about duties, now began to demand protection against competition from beyond the sea. To this factor was added the revival of national feeling and prejudice, with growing political complications and jealousies. Hence, by gradual steps, the customs policy of France has become more and more strongly restrictive. The first important step was taken in 1881, when a new general tariff was established, in which specific duties replaced the *ad valorem* duties chiefly applied in the treaty tariffs of 1860–66. The new rates were supposed to be no more than equivalent to those replaced by them, but in fact were in some cases higher. New treaty tariffs, less liberal than the earlier ones, were concluded with Belgium, Switzerland and Spain; while with other countries (*e.g.* Great Britain) a "most favoured nation" arrangement was substituted for the previous treaty régime. These new treaty arrangements expired in 1892: even before that date, duties had been raised on grain and meats; and finally, in 1892, a new and more highly protective general tariff was established on the recommendation of M. Méline, with high duties on agricultural products and raw materials as well as on manufactures, and with provisions for limited domestic bounties on silk, hemp and flax. Nevertheless, some provision was made for negotiations with foreign countries by establishing a minimum tariff, with rates lower than those of the general or maximum tariff, the rates of this minimum tariff being applicable to countries which might make concessions to France. As a rule the minimum tariff has been applied, after negotiation, and thus is the tariff in practical effect; yet its rates are still high, and, most significant of all, agricultural products are granted no reductions whatever as compared with the maximum tariff, there being heavy and unrelaxed duties upon grain, animals, meats and the like.

Tariff of 1892.

The Zollverein, 1834.

Germany.—The tariff history of Germany, up to the foundation of the German Empire, is the history of the Zollverein or German customs union; and this in turn is closely connected with the tariff history of Prussia. In 1818 Prussia adopted a tariff with much reduced duties, under the influence of the Liberal statesmen then still powerful in the Prussian government. The excitement and opposition in Germany to the Prussian tariff led to customs legislation by the other German states, some smaller states joining Prussia, while the southern states endeavoured to form independent customs unions. Finally, by gradual steps between 1831 and 1834, the complete Zollverein was formed, notwithstanding popular opposition. All the German states formed a customs union, with free trade between them, except so far as differing internal taxes in the several states made some modifications necessary. The customs revenue was divided among the several states in proportion to population. The tariff of the Zollverein was, in essentials, the Prussian tariff of 1818, and was moderate as compared with most of the separate tariffs previously existing. Within the Zollverein, after 1834, there was an almost unceasing struggle between the Protectionist and Free Trade parties, Prussia supporting in the main a Liberal policy, while the South German states supported a Protectionist policy. The trend of the tariff policy of the Zollverein for some time after 1834 was towards protection; partly because the specific duties of 1818 became proportionately heavier as manufactured commodities fell in price, partly because some actual changes in rates were made in response to the demands of the Protectionist states. In 1853 a treaty between the Zollverein and Austria brought about reciprocal reductions of duty between these two parties. After 1860 a change towards a more liberal policy was brought about by the efforts of Prussia, which concluded independently a commercial treaty with France, forcing on the other members of the Zollverein the alternative of either parting company with Prussia or of joining her in her relations with France. The second alternative was accepted, largely because Austria did not vigorously support the South German states, and in 1865 the Zollverein as a whole concluded a commercial treaty with France, bringing about important reductions of duty. The régime of comparatively free

French treaty and low tariff, 1865.

trade thus established lasted for about fifteen years. After the foundation of the German Empire, the duties of the Zollverein became those of Germany, and for a time the liberal régime was maintained and extended, with respect to the tariff as with respect to other matters. But in Germany, as in France, a combination of political and of economic forces led before long to a reaction towards protection. Bismarck broke with the National Liberals, who were the champions of free trade; at the same time the agricultural depression set in, and the agricultural interest demanded protection against American and other foreign competition. The manufacturers, especially of iron, also manoeuvred for protection. The reaction came in 1879, when duties were increased on manufactured articles as well as on agricultural articles. Other advances of duty were made in later years, especially on grain; and thus the policy of Germany has become distinctly Protectionist, though not to the same degree as in France. In 1892, however, the precise year in which France gave up her system of commercial treaties, some moderation was brought about in Germany's protective system by commercial treaties with Austria, Italy, Belgium, Switzerland, and shortly afterwards with Russia. These treaties provided for reductions of duties in all directions, the most important concessions being on certain agricultural products. Thus the duty on wheat, which had been gradually raised as high as 5 marks per hundred kilogrammes (roughly 1s. 3d., or about 30 c. a bushel) was reduced to 3·50 marks by the treaties. The rates of these treaties were extended to a number of other countries having "most favoured nation" relations with Germany. The tariff system of Germany, however, at the beginning of the 20th century, remained definitely Protectionist.

Protection reinstated, 1879.

In other important countries changes in policy have taken place similar to those noted in Germany and in France. The era of moderated tariffs, which began with the great treaty of 1860, lasted for about twenty years, and was followed in Italy, Austria, Belgium, Switzerland and Spain by a reversion to protection, although usually to a less high system of protection than had prevailed before 1860. The United Kingdom and Holland alone held consistently and unfalteringly to the principle of free trade. The factors which have brought about this reaction have been, as was already noted, partly economic, partly political: on the one hand, the pressure of competition from distant countries in agricultural products, a consequence chiefly of improved transportation; on the other hand, the revival of national sentiment and prejudice.

The United States.—The tariff history of the United States, like that of European countries, divides itself into two great periods, before and after the year 1860. But it is no more than an accident that this year constitutes the dividing line in both cases, the change in the United States being due to the Civil War, which so profoundly influenced the fiscal, economic and political history of the country in all directions. The period before 1860 may again be divided into three sub-periods, the first extending from 1789 to 1816, the second from 1816 to about 1846, the third from 1846 to 1860.

(1) The Tariff Act of 1789 was the first legislative measure passed by the United States. The Protectionists have pointed to it as showing the disposition of the first Congress to adopt at once a policy of protection; the Free Traders have pointed to it similarly as showing a predilection for their policy. Each had some ground for the claim. The duties of the act of 1789 were very moderate, and, as compared with those which the United States has had under any subsequent legislation, may be described as free trade duties. On the other hand, the spirit of the act of 1789 was protective. It had been the design of Madison, and of other firm supporters of the new constitution, to adopt in 1789 a very simple measure, designed solely to secure revenue. But the pressure from the representatives of some of the states, notably Pennsylvania and Massachusetts, compelled him to incorporate in the Tariff Act certain specific duties borrowed from the Tariff Acts then in force in these states, which had a distinctly protective aim. Thus the act of 1789, although the duties levied by it were moderate, yet had a protective intent. Such in the main remained the situation until 1816, duties being indeed raised from time to time in order to secure more revenue, but the arrangement and the general rate of the duties not being sensibly modified. There was not at this time any considerable public feeling on the subject of protection, chiefly because during most of the years of this period the Eastern states, and especially New England, where manufactures might be expected to develop first, were profitably engaged in an extensive export and carrying trade.

1789–1816.

(2) After the close of the War of 1812, however, a new spirit and a new policy developed. With the end of the Napoleonic wars, the opportunities for American commerce became less, while at the same time the expanding population necessarily led to diversified interests at home. A demand arose for two closely connected measures: protection to domestic manufactures, and internal improvements. Protection was demanded as a means both of aiding young industries and of fostering a home market for agricultural products. The chief spokesman of the new movement was Henry Clay, who remained throughout his life the constant advocate of this so-called "American system." Some disposition in this direction showed itself as early as 1816, when tariff duties were raised. Still greater changes were made in 1824, 1828, and 1832. In 1824 duties were considerably raised; and thereafter the New England states, which so far had been lukewarm in supporting the movement, joined in it unreservedly. The tariff of 1828 was affected by some political manipulation, which caused it to contain objectionable provisions, and to be dubbed "the tariff of abominations." But the so-called abominations were removed in 1832, when the protective system was deliberately and carefully rearranged. By this time, however, the opposition to it in the South had reached a pitch so intense that concessions had to be made. As a planting and slave-owning region, the South inevitably had no manufactures: it felt that its cotton was sure to find a foreign market, and would gain little from the establishment of a domestic cotton manufacture within the country; and it judged, rightly, that the protective system brought it only burden and no benefit. The extent of the burden was greatly exaggerated by the leaders of the South, especially in the heat of partisan controversy; and the subject was closely connected with the controversy as to the rights of the states, and the endeavour of South Carolina, under the influence of Calhoun, to nullify the Tariff Act of 1832. The nullification movement led in 1833 to the well-known compromise, by which the rates of duty as established by the Act of 1832 were to be gradually reduced, reaching in 1842 a general level of 20 per cent. The compromise served its turn in allaying political bitterness and staving off a direct conflict between the United States and South Carolina. But the reductions of duty made under it were never effectively carried out. In 1842, when the final 20 per cent. rate was to have gone into effect, the Protectionists again had control of Congress, and after a brief period of two months, during which this 20 per cent. rate was in force, passed the Tariff Act of 1842, which once more restored the protective system in a form not much less extreme than that of 1832.

1816–46.

(3) Four years later, however, in 1846, a very considerable change was secured by the South, and a new era was entered on. The Democratic party now was in control of legislation, and in the Tariff Act of 1846 established a system of moderate and purely *ad valorem* duties, in which the protected articles were subjected, as a rule, to a rate of 30 per cent., in some cases to rates of 25 and 20 per cent. The system then established has often been spoken of as a free trade system, but was in reality only a system of moderated protection. In 1857 duties were still further reduced, the rate on most protected commodities going down to 24 per cent., and remaining at this comparatively low level until the outbreak of the Civil War.

1846–60.

The second great period in the tariff history of the United States opens with the Civil War. It is true that the first steps towards a policy of higher protection were taken just before the war began. In the session of 1860–61, immediately preceding the outbreak of the conflict, the Morrill Tariff Act was passed by the Republican party, then in control because the defection of Southern members of Congress had already begun. It substituted specific duties for the *ad valorem* duties of 1846 and 1857, and made some other changes of significance, as in the higher duties upon iron and steel. Nevertheless, the advances then made were of little importance as compared with the far-reaching increases of duty during the Civil War. These formed part of the general resort to every possible fiscal device. The great struggle compelled every resource to be strained to the utmost: the issue of long-time bonds, continual borrowing in very large amounts on short-time inconvertible paper money, an elaborate and all-pervading system of internal taxes, and, finally, heavy import duties. The internal taxes of the war were applied not only in the form of income taxes, stamp taxes, licence and gross receipts taxes, but also as direct excise taxes on many commodities. The import duties were correspondingly raised, partly by way of off-set to the internal taxes, partly as a means of getting additional revenue, and finally in some degree because of a disposition to protect domestic industries. The most important acts were the great revenue acts of 1862 and 1864. Some further changes were made in 1865, and the close of the war thus left the United States with a complicated system of very high taxes both on imported duties and on domestic products.

The War tariff, 1862-64.

The main features of the tariff history of the United States since the Civil War have been that the internal taxes have been almost entirely swept away, the import duties on purely revenue articles similarly abolished, while those import duties that operated to protect domestic industries have been maintained, and indeed in many cases increased. The situation has had some analogy to that of France from 1815 to 1860, when similarly a highly restrictive system established during a period of war was unexpectedly retained long after peace had been established. This result in the United States came about by gradual steps and without premeditation. After the close of the war efforts were first directed to clearing the financial situation by funding the floating debt, and taking steps (never fully consummated) towards contracting the currency. Next the internal taxes were gradually done away with, until nothing was left except the excise on beer, spirits and tobacco. No further resort was made to internal taxes until the revenue act of 1898 was passed, at the outbreak of the Spanish War. Efforts were made also to reduce the tariff duties, but these naturally came last: they met with strong opposition, and in the end they were almost completely frustrated, thus leaving as the basis of the tariff the rates which had been levied in the course of the war. In 1870 some rearrangements were made, the duties on iron and on some other articles being reduced. In 1872 a more general reduction was carried out, strongly resisted by the Protectionists, and finally ending in a uniform cutting off of 10 per cent. from all the import protective duties. In 1875, however, when the revenue had become deficient after the crisis of 1873, the 10 per cent. reduction was repealed, and duties restored to their previous amounts. It deserves to be noted that in 1872 an important step was also taken towards removing entirely the duties on purely revenue articles, tea and coffee being then admitted free of duty. On the other hand, the maintenance of the protective duties, and the gradual consolidation of feeling in favour of a permanent policy of strong protection, led to other revisions and rearrangements in the direction of protection. In 1867 an important act on wool and woollens was passed, largely increasing the duties on both. In 1869 the duty on copper was raised. In 1870, while some duties were lowered, others were raised, as, for instance, those on steel rails and on marble. Thus the ten years immediately following the close of the war brought about the gradual transformation of the high duties levied on all commodities for revenue purposes into a system of high duties almost wholly on protective commodities. This transformation met with much opposition, not less in the Republican party than in the Democratic party. While the feeling in the Republican party had been from the outset in favour of protection, so high a range of duties met with much opposition. This opposition led to an important general revision in 1883, largely influenced by the recommendations of a special Tariff Commission which Congress created in 1882. The act of 1883 was passed in the main as a party measure by the Republicans, and on the whole served rather to put in order the protective system as it stood than to make any change of policy. Certain duties were reduced (though in no case greatly reduced) such as those upon wool, some woollens, cheaper grades of cotton cloths, iron, steel rails, copper. On the other hand, on many articles duties already high, but believed to be insufficient for the effective protection of the domestic producer, were raised; *e.g.*, on finer woollens and cottons, on some iron and steel manufactures.

Gradual consolidation of war duties.

Revision of 1883.

The tariff system as revised and codified in 1883 would probably have remained unchanged for many years had it not been for the turn taken by political and financial history. The decade from 1880 to 1890 was one of great prosperity, consequently of rising imports, consequently of swelling customs revenue. In the second half of the decade a continuous large surplus in the Treasury necessarily directed attention to the state of the revenue, and gave strength to the protests against excessive taxation. In addition, the Democratic party, which had long been committed, though in a half-hearted way, against the policy of high protection, was brought to a vigorous and uncompromising attack on it through the leadership of President Cleveland. In his Presidential Message of December 1887 he attacked the protective system in unqualified terms; and in the session of 1887–88 the Democratic majority in the House of Representatives prepared a bill providing for great reductions. The control of the Senate by the Republicans prevented any legislation. But the Republicans, as is almost inevitable under a party system, championed the policy opposed by the other side, and declared themselves not only in favour of the maintenance of existing duties, but of the consistent and unqualified further application of protection. The protection question thus became the main issue in the Presidential election of 1888, which resulted in the defeat of the Democrats. In the next ensuing session of Congress, in 1889–90, the Republicans passed a new tariff act, known as the McKinley Tariff Act, because Mr McKinley was then chairman of the House Committee in charge of the bill. It advanced duties materially on a considerable number of commodities, both raw materials and manufactured articles. The duties on wool were raised, corresponding changes made on woollen goods, the duties on cottons, linens, some silks, and velvets considerably raised. A further step towards consolidating the protective system was taken by abolishing the duty on sugar, mainly a revenue duty. The necessity for reducing the revenue and cutting down the continued surplus was met in this way rather than by lowering the protective duties. For consistency in maintaining the protective principle a direct bounty was given to the domestic producers of sugar in Louisiana. A turn in the political wheel brought an abrupt change four years later, in 1894. The tariff question was again the issue in 1892: President Cleveland, defeated four years before, was now again elected, and the Democratic party came into power, pledged to change the tariff system. Accordingly in the first ensuing session of the Congress elected in 1892 the tariff act of 1894 was passed, known as the Wilson Tariff, bringing about considerable reductions of duty. The measure, however, was less incisive than its chief sponsors had planned, because of the narrow majority commanded by the Democrats in the Senate. Some of the Democratic senators were lukewarm in their support of the party policy of tariff reduction, and joined with the Republicans in mitigating the changes. Nevertheless some crucial changes were made. The duty on wool, typical among the duties on raw materials, was completely abolished, and with this change came a great reduction in the duties upon woollen goods. Changes, but of less importance, were made on other

McKinley tariff of 1890.

Wilson tariff of 1894.

textile goods. The House had proposed to remove also the duties on coal and on iron ore, but the Senate permitted only a reduction in these. A duty was reimposed on sugar, chiefly as a means of securing needed revenue, but at a less rate than had existed before 1890. At the same time the differential duty on refined sugar, which operated as protection to the sugar trust, was not abolished, as the ardent tariff reformers had proposed, but kept in substance not greatly changed. This circumstance, as well as the failure to make other desired reductions, caused the ardent tariff reformers to be greatly disappointed with the act of 1894 as finally passed, and led President Cleveland to permit it to become law without its endorsement by his signature. The next election in 1896 brought still another turn in the political wheel, the Republicans being once more brought into power under the leadership of President McKinley. The currency issue had been foremost in the campaign, but the Republicans had also proclaimed themselves in favour of a return to the unqualified protective system. At the extra session which President McKinley called in 1897, almost the sole measure considered was the tariff act, known (again from the name of the chairman of the House Committee) as the Dingley Act. This reimposed the duties upon wool, on most qualities at the precise rates of 1890, on some qualities at even higher rates. Necessarily the duties on woollens were correspondingly raised, and here again made even higher than they had been in 1890. On other textiles, particularly on silks and linens, similar advances were made. As a rule, the duties of 1890 were either retained or somewhat advanced. To this policy, however, there was a significant exception in the iron and steel schedule, where the reduced duties of 1894 were left mainly unchanged. The iron industry in the United States had made extraordinary advances, and confessedly was not in need of greater protection than had been given in 1894. Some provisions for reciprocity arrangements with other countries, opening the way for possible reductions of duty by treaty arrangements, were also incorporated in the act of 1897, though with limitations which made it improbable that any considerable changes would ensue from this policy. Some such provisions had also been contained in the act of 1890, but here also without important results. The tariff system of the United States at the beginning of the 20th century thus remained rigidly and unqualifiedly protective, with rates higher than those of even the most restrictive tariffs of the countries of the European continent.

Dingley tariff of 1897.

TARIJA, or TARIXA, a department and town of south-eastern Bolivia. The department lies on the northern frontier of Argentina, and is bounded W. by Potosí, N. by Chuquisaca, and E. by Paraguay. Pop. (1900) 102,887. Area, 33,036 sq. m. The eastern and larger part of the department belongs to the great Chaco region. The Chaco districts are inhabited by small nomadic tribes of Indians, and the grassy Llanos de Manzo by the Chiriguanos, one of the strong Indian nations of South America. They are considered a branch of the Guarany race, and live in permanent villages, breed horses, cattle and sheep, and till the soil. Near the Argentine frontier are the less civilized tribes of the Tobas, and in the mountainous districts are remnants of the Quichuas, once masters of an empire.

The capital, SAN BERNARDO DE TARIJA (pop. 1900, 6980; 1906, estimate, 7817), is the only town of importance in the department. It is situated on the Rio Grande de Tarija, about 100 m. E. of Tupiza. It is about 5800 ft. above sea level and its climate is mild and healthy. The town was founded in 1577 by Luiz de Fuertes, by orders of the Viceroy of Peru, as a military post to hold the Chiriguanos in check. About the same time the Jesuits established themselves here, and the most important building in the town is their convent, afterwards occupied by the Franciscans.

TARIM, the principal river of Chinese or Eastern Turkestan, in the middle of Asia. It rises in two head-streams, (1) the Kashgar-darya, which springs as the Kyzyl-su on the N. versant of the Pamir plateau, not far from another Kyzyl-su or the Vakhsh, which flows down the Alai valley to join eventually the Amu-darya, and (2) the Yarkand-darya, which gushes out under the name of the Raskan-darya, on the N. slope of the Karakorum Mountains, just under the Karakorum pass. The former stream flows almost due E. past the city of Kashgar until it joins the Yarkand or Yarkent-darya. The latter, after skirting, in a deep gorge and in a north-western direction, the S. foot of the Sughet Mountains and then of the Raskem Mountains, both constituent members of the western Kuen-lun, forces its way out into the lowlands of Eastern Turkestan and flows N. past the city of Yarkand, then turns N.E. and traverses in a gigantic arc the N.W., N., and E. margins of the vast desert of Takla-makan. Of these two streams Dr Sven Hedin concedes the honour of being the mother river to the Yarkand-darya, on the ground both of its length and of its volume; indeed for some months in the year the Kashgar-darya, mainly owing to the drain made upon it for irrigation purposes after it debouches upon the lowlands, fails to get through to the Yarkand-darya, whereas the Yarkand-darya, on the other hand, never dries up.

The Kashgar-darya enters the Yarkand-darya by a wide delta of anastomosing arms, beginning in the vicinity of Maral-bashi (39° 49′ N. and 78° 33′ E.). The conjoint river, bearing the name of the Yarkand-darya, flows for some 230 m. N.E. until it encounters the Ak-su-darya from the N. Along this part of its course the river is full of minor sinuosities, with a deep, narrow channel, a sluggish current, and high steep banks, bordered by forests of poplars and thickets of reeds. The Ak-su-darya, which rises at an altitude of 11,000 ft. as the Ak-sai near the S.W. extremity, but on the W. side, of the Kokshal-tau range of the Tian-shan Mountains, soon breaks through that range and proceeds to flow E.N.E. along its southern foot, but under the name of the Taushkan-darya, until it reaches the town of Ak-su in 80° 41′ E. and 40° 28′ N. Thence it flows S. and S.E. and effects a junction with the Yarkand-darya (Tarim) in about 81° E. The Ak-su, which is swift and brings down large quantities of sediment, infuses new vigour into the main river, giving it an impulse which carries it all the way down to the Kara-koshun.

About 20 m. farther down, the Yumalak-darya or Tarim, as the river then begins to be called, is joined on the right or S. by the Khotan-darya, a stream which rises in the N. ranges of the Kuen-lun Mountains, and fights its way across the all-engulfing sands of the desert of Takla-makan, but with such poor results that it is only about forty days in the year that it makes any contribution to the volume of the Tarim. Some 180 to 190 m. below the confluence of the Ak-su-darya, the river begins to come into direct conflict with the sand-dunes of the great desert, which it has thus far successfully skirted. At the same time it begins to waste its strength in filling marginal or lateral lakes, formed in the hollows between the big sand-dunes (they reach elevations of as much as 300 ft.).

In about 86° 30′ E., near the station of Karaul, the river begins to break up in deltaic fashion, and in a long secular process, using Karaul as a sort of pivot, appears to oscillate backwards and forwards like a pendulum from N. to S., and from S. back again to N. between the lake of Kara-koshun (N. M. Przhevalsky's Lop-nor) at the N. foot of the Astin-tagh (see LOP-NOR), and the basin at the S. foot of the Kuruk-tagh (see GOBI), which Baron von Richthofen and Dr Sven Hedin identify with the ancient Lop-nor of the old Chinese geographers. From Karaul down to Ayrilghan or Arghan, a distance of over 200 m., the Tarim skirts the N.E. front of the high sand-dunes of the great desert, spending itself in numerous marginal lakes all the way down, while on the opposite bank (left) it leaves numerous interlacing branches behind it, like the Kunchekish-tarim, Lashin-darya, Yätim-tarim, Ilek, and Tokuz-tarim. None of its marginal lakes is round in shape, but all are elongated, from N. to S. or from N.W. to S.E. This is the general rule, but there is a second series of lakes beside the river which are drawn out from N.E. to S.W. These owe their existence primarily to the action of the wind. Here too, in its delta, the Tarim overflows into more than one chain of a third category of lakes (*e.g.* Avullu-kol, Kara-kol, Tayek-kol, and Arka-kol), strung on one or other of its anastomosing deltaic arms. These generally act as regulators and clarifiers, the river emerging from them with crystal-bright water.

Near the head of its delta the Tarim is joined from the N. by the Koncheh-darya, a stream which issues from the lake of Bagrash-kul, its ultimate source being the Khaidu-gol or Khaidyk-gol, which drains the Yulduz valleys of the eastern Tian-shan Mountains. This river, which measures 290 m. from the Bagrash-kul to the Kara-koshun, serves, with the help of the poplar forest which grows along its left bank, as a dam to check the westward movement of the desert sands. Finally the Tarim enters, by a number of arms, the series of shallow, dwindling lakes of Kara-buran, which serve as a sort of lacustrine ante-room to the real terminal basin of the river, the Kara-koshun, which lies a little farther to the E., in 40° N., 89° 30′ E., at an altitude of 2675 feet above sea-level. In 1900–01 Dr Sven Hedin discovered several fresh desert lakes forming to the N. of Kara-koshun, and branches of the deltaic arms of the Tarim, or overflows of such branches, straining out in the same direction, facts which he interpreted as a tendency of the river to revert to its former more northerly terminal basin of the old (Chinese) Lop-nor.

The river not only dwindles vastly between the confluence of the Ak-su (*e.g.* 16,780 cub. ft. in the second in June) and its embouchure in the Kara-koshun (5650 cub. ft. in the second), but keeps on lifting its bed and its current, like the Po and the Hwang-ho, above the level of the adjacent country. The total fall from the confluence of the Ak-su-darya (3380 ft.) to the Kara-koshun (2675 ft.), a distance of some 665 m., is only 705 ft., giving an average of very little more than a foot per mile. The total length of the river is probably somewhere near 1000 m. On the whole the Tarim is step by step and year by year steadily but slowly working its way towards the S.W., for all along its lower course it is accompanied by a belt, some 50 m. wide, which lies at a lower level or altitude than itself. In its actual delta this tendency is counterbalanced by its incipient oscillation backwards towards the N., towards the desiccated lake basin of the old Lop-nor. Although the river drains the vast area of 354,000 sq. m., it is only from 172,000 sq. m. of this (48·8 per cent.) that it derives any augmentation of volume. The remaining 182,000 sq. m. (51·2 per cent.) of the potential catchment area fails to contribute one drop of water, being nothing but arid, rainless desert. Throughout the catchment-basin of the Tarim the precipitation is governed by the general law, that it increases from N. to S. and from E. to W. Hence, in conformity with this, the largest affluents are in the west. In general shape the basin of the Tarim is elliptical, but the lowest part lies near the extreme E. end of the ellipse. "If the deepest part of the basin lay beyond the long axis of the ellipse the symmetry would be ideal; but, situated as it is at the southern foot of the Tian-shan, it has occasioned a dislocation towards the N. of the main stream of the system. . . . If we compare the northern peripheral zone from the catchment area of the Kashgar-darya to the catchment area of the Kuruk-tagh, both inclusive, with the southern peripheral zone from the catchment area of the Yarkand-darya to the catchment area of the Astin-tagh, both again inclusive, we find that the former has an area of 82,990 sq. m., and the latter an area of 89,550 sq. m., or, in other words, that they are approximately of the same size. In the case of both the breadth decreases on the whole towards the E., until they each terminate in a narrow strip, the domain of the Kuruk-tagh on the one hand and that of the Astin-tagh on the other. But before they contract in this way the zones swell out into the Khaidu-gol and the Cherchen-darya and Kara-muran respectively. . . . A corresponding symmetry can also be seen in the rivers which gather off the encircling mountains into the depression," [1] the Kashgar-darya balancing the Yarkand-darya, the Ak-su-darya balancing the Khotan-darya, the Koncheh-darya balancing the Cherchen-darya, and so on.

The Tarim begins to freeze about the end of November and the freezing advances upwards against the current. When the ice of the river thaws in the beginning of March it sets up a spring flood, which in magnitude and volume falls little short of the flood caused by the melting of the snows on the mountains about the head-streams and feeders of the river, and the course of which can be traced all down the Tarim during the summer and autumn. The river abounds in fish, especially in the lower part of its course. Fish forms the staple food of a large part of the riverine population.

See Sven Hedin, *Scientific Results of a Journey in Central Asia, 1899–1902* (vols. i. and ii., Stockholm, 1905–06), and *Central Asia and Tibet* (2 vols., London, 1903). (J. T. Be.)

[1] Sven Hedin, *Scientific Results*, ii. 524–25.

TARKANI, or Tarkalanri, a Pathan tribe inhabiting the whole of Bajour (*q.v.*), on the border of the North-West Frontier Province of India. Subdivided into Mamunds, Isazai and Ismailzai, the tribe numbers some 100,000 persons.

TARLETON, SIR BANASTRE (1754–1833), English soldier, was the son of John Tarleton (1719–1773), a Liverpool merchant, and was born in Liverpool on the 21st of August 1754. Educated at Oxford he entered the army, and in December 1775 he sailed as a volunteer to America with Earl, afterwards Marquess, Cornwallis, and his services during the American War of Independence in the year 1776 gained for him the position of a brigade major of cavalry. He was present at the battle of Brandywine and at other engagements in 1777 and 1778, and as the commander of the British legion, a mixed force of cavalry and light infantry, he proceeded at the beginning of 1780 to South Carolina, rendering valuable services to Sir Henry Clinton in the operations which culminated in the capture of Charleston. He was responsible for a British victory at Waxhaw in May 1780, and he materially helped Cornwallis to win the battle of Camden in the succeeding August. He was completely victorious in an engagement with Thomas Sumter at Fishing Creek, or Catawba Fords, but was not equally successful when he encountered the same general at Blackstock Hill in November 1780; then in January 1781, in spite of much personal valour, he was defeated with heavy loss at Cowpens. Having been successful in a skirmish at Tarrants House, and having taken part in the battle of Guilford in March 1781, he marched with Cornwallis into Virginia, and after affording much assistance to his commander-in-chief he was instructed to hold Gloucester. This post, however, was surrendered to the Americans with Yorktown in October 1781, and Tarleton returned to England on parole. In 1790 he entered parliament as member for Liverpool, and with the exception of a single year he remained in the House of Commons until 1812. In 1794 he became a major-general; in 1812 a general; and he held a military command in Ireland and another in England. In 1815 he was made a baronet. He died without issue at Leintwardine in Shropshire on the 25th of January 1833.

For some time Tarleton lived with the actress Mary Robinson (Perdita), and his portrait was painted both by Reynolds and by Gainsborough. Sir Banastre wrote a *History of the Campaigns of 1780 and 1781 in the Southern Provinces of North America* (London, 1781), which, although of some value, is marred by the author's vanity and by his attacks on Cornwallis. It was criticized by Colonel Roderick Mackenzie in his *Strictures on Lieutenant-Colonel Tarleton's History* (1781) and in the *Cornwallis Correspondence*.

TARLTON, RICHARD (d. 1588), English actor, was probably at one time an inn-keeper, but in 1583, when he is mentioned as one of the original company of queen's players, was already an experienced actor. He was Elizabeth's favourite clown, and his talent for impromptu doggerel on subjects suggested by his audience has given his name to that form of verse. To obtain the advantage of his popularity a great number of songs and witticisms of the day were attributed to him, and after his death *Tarlton's Jests*, many of them older than he, made several volumes. Other books, and several ballads, coupled his name with their titles. He is said to have been the Yorick of Hamlet's soliloquy.

TARN, a river of southern France, tributary to the Garonne, watering the departments of Lozère, Aveyron, Tarn, Haute-Garonne and Tarn-et-Garonne. Length, 234 m. Area of basin, 5733 sq. m. Rising on the southern slope of Mt. Lozère at a height of 5249 ft., the Tarn flows westward and, having received the Tarnon, enters the gorge, famed for its beauty, which separates the Causse de Sauveterre from the Causse Méjan. Emerging from this cañon after a course of 37 m. it receives the Jonte on the left and, still flowing through gorges, passes between the Causse Noir, the Larzac plateau and the Causse de St Affrique (at the foot of which it receives the Dourdou de Vabre) on the left and the Lévezou range and the Plateau of Ségala on the right. In this part of its course the most important town is Millau, where it receives the Dourbie. At the cascade of Sabo, above Albi, the river enters the plains and, flowing in a deep bed, passes Albi and Gaillac, some distance below which, at the confluence of the Agoût, it exchanges a west-south-westerly for a north-westerly course. At Montauban the Tarn receives the Tescou and 6 m. farther on unites with the Aveyron. It then reaches Moissac, 2½ m. below which it flows into the Garonne.

TARN, a department of south-western France, formed in 1790 of the three dioceses of Albi, Castres and Lavaur, belonging to the province of Languedoc. Pop. (1906) 330,533. Area, 2231 sq. m. Tarn is bounded N. and E. by Aveyron, S.E. by Hérault, S. by Aude, S.W. and W. by Haute-Garonne, N.W. by Tarn-et-Garonne. The slope of the department is from east to west, and its general character is mountainous or hilly; its three principal ranges, the Mountains of Lacaune, the Sidobre, and the Montagne Noire, belonging to the Cevennes, lie on the south-east. The stony and wind-blown slopes of the first-named are used for pasturage. The highest point of the range and of the department is the Pic de Montalet (about 4150 ft.); several other summits are not much short of this. The granite-strewn plateaus of the Sidobre, from 1600 to 2000 ft. high, separate the valley of the Agoût from that of its left-hand affluent the Thoré. The Montagne Noire, on the southern border of the department, derives its name from the forests on its northern slope, and some of its peaks are from 3000 to 3500 ft. high. The limestone and sandstone foot-hills are clothed with vines and fruit trees, and are broken by deep alluvial valleys of extraordinary fertility. With the exception of a small portion of the Montagne Noire, which drains into the Aude, the whole department belongs to the basin of the Garonne. The eastern portion of the department has the climate of Auvergne, the severest in France, but that of the plain is Girondin. At Albi the mean temperature is 55°. The rainfall, 29 or 30 ins. at that place, exceeds 40 ins. on the Lacaune and Montagne Noire.

The most noteworthy places in the department are Albi, the capital, Castres, Gaillac, Lavaur, Mazamet and Cordes, which are separately treated. Other places of interest are Burlats, which has ruins of an old church and château; Lisle d'Albi, a *bastide* with a church of the 14th century; and Penne, which has ruins of a fine medieval château.

TARN (O. Eng. *tarne*, Scand. *tjarn*, *tjärn*, *tjörn*, &c.), a name applied in England (especially in the Lake District) and in Scotland to small lakes or pools in mountainous districts, especially to such as have no visible affluent streams. The term is sometimes used also of a marsh or bog.

TARN-ET-GARONNE, a department of south-western France, formed in 1808 of districts formerly belonging to Guienne and Gascony (Quercy, Lomagne, Armagnac, Rouergue, Agenais), with the addition of a small piece of Languedoc. From 1790 to 1808 its territory was divided between the departments of Lot, Haute-Garonne, Tarn, Aveyron, Gers and Lot-et-Garonne. It is bounded N. by Lot, E. by Aveyron, S. by Tarn and Haute-Garonne, and W. by Gers and Lot-et-Garonne. Area, 1440 sq. m. Pop. (1906) 188,553. The department is watered by three rivers, the Garonne, the Tarn, which joins the Garonne below Moissac, and the Aveyron, which flows into the Tarn between Moissac and Montauban, dividing it into three distinct regions of hills. Those to the south-west of the Garonne are a continuation of the plateau of Lannemezan; ramifications of the Cevennes extend between the Garonne and the Tarn, and between the Tarn and the Aveyron; the region to the north of the continuous valley formed by the courses of the three rivers belongs to the Central Plateau. The *causse* or limestone plateau of Quercy occupies the north-east corner of the department and includes its highest point (1634 ft.). The lowest point (164 ft.) is at the exit of the Garonne. The climate is mild and agreeable; the mean annual temperature being about 56° F. Rain falls seldom, but heavily, especially in spring, the annual rainfall being 28 or 30 ins.

The wide alluvial valleys of the three large rivers are most productive. Cereals, especially wheat, maize and oats, occupy more than two-thirds of the arable land of the department. The vine is everywhere cultivated and large quantities of grapes are exported as table fruit. Potatoes are also grown. Plums and apricots are abundant. The breeding of horses, especially for cavalry purposes, is actively carried on; and the rearing of horned cattle, both for draught and for fattening, is also important. Sheep, pigs, poultry and, in a minor degree, silk-worms, are also sources of profit. The manufacturing industry is represented by flour-mills, metal-foundries, tanneries, various kinds of silk-mills, and manufactories of linen, wool and paper. The principal exports are fruit, wine, flour, truffles from the Rouergue, poultry, phosphates and lithographic stone. Imports include raw materials for textile industries, timber, iron, wood-pulp, coal and agricultural produce. The canal of the Garonne traverses the department for 48 m. and the Garonne and the Tarn furnish 82 m. of navigable waterway. The department is served by the Orleans and the Southern railways. The department forms the diocese of Montauban, and belongs to the jurisdiction of the Toulouse court of appeal, to the *académie* (educational division) of Toulouse, and to the district of the XVII. corps d'armée (Toulouse). It has 3 arrondissements (Montauban, Moissac and Castelsarrasin), 24 cantons and 195 communes.

Montauban, Moissac and Castelsarrasin are the principal places. Other towns of interest are St Antonin, which has tanneries and manufactures of rough fabrics and is archaeologically important for its possession of a massive hôtel de ville of the 12th century, the oldest in France; Bruniquel, which is splendidly situated overlooking the valleys of the Aveyron and the Vère, and is dominated by a medieval castle with a donjon of the 11th century; Beaumont-de-Lomagne, a curious *bastide* of the 13th century with a fortified church of the 14th century; Montpezat-de-Quercy, which has a church of the same period, containing many precious antiquities; Varen, an ancient town of narrow streets and old houses with a remarkable Romanesque church and the ruins of a castle of the 14th and 15th centuries; and Ginals, where remains of the Cistercian abbey of Beaulieu, founded in 1141, are still to be seen.

TARNOPOL, a town in Galicia, Austria, 87 m. E.S.E. of Lemberg by rail. Pop. (1900) 30,368, half of which are Jews. Industry consists chiefly in corn-milling and the preparation of wax and honey. The principal trade is in horses, corn and other agricultural produce, and spirits. Tarnopol was formerly a fortress, and rendered valuable services to Polish kings, who in their turn conferred upon it important privileges.

TARNOW, a town in Galicia, Austria, 164 m. W.N.W. of Lemberg by rail. Pop. (1900) 31,691, about 40 per cent. Jews. It is situated on the river Biala, not far from its junction with the Dunajec, and is the seat of a Roman Catholic bishop. It possesses a cathedral in Gothic style, built in the 15th century, with monuments of the Tarnowski and Ostrogski families, to which the town formerly belonged, and another church built in 1454. On the Martinsberg, an eminence near the town, stands the ruins of the old castle of the Tarnowski family, and a small church over 800 years old. Worth mentioning also is the town hall, an old and interesting building. Agricultural implements, glass and chicory are manufactured.

TARNOWSKI, JAN [called MAGNUS] (1488–1561), Polish general. After a careful education beneath the eye of an excellent mother and subsequently at the palace of Matthew Drzewicki, bishop of Przemysl, he occupied a conspicuous position at court in the reigns of John Albert, Alexander and Sigismund I. As early as 1509 Tarnowski brilliantly distinguished himself in Moldavia, and took a leading part in the great victories of Wisniowiec (1512) and Orsza (1514), where he commanded the flower of the Polish chivalry. To complete his education he then travelled in Palestine, Syria, Arabia, Egypt, and northern and western Europe. While in Portugal he received from King Emanuel the chief command in the war against the Moors, and Charles V. rewarded his services in the Christian cause with the dignity of a count of the Empire. Indeed, the emperor had such a high regard for Tarnowski that he offered him the leadership of all the forces of Europe in a grand expedition against the Turks. On the death of Nicholas Firlej in 1526 Tarnowski became grand hetman of the crown, or Polish commander-in-chief, and in that capacity won his greatest victory at Obertyn (22nd August 1531) over the Moldavians, Turks and Tatars, for which he received a handsome subsidy and an ovation similar to that of an ancient Roman triumphator. Heartily attached to King Sigismund I. and his son Sigismund Augustus, Tarnowski took the royal side during the so-called *Kokosza wojna*, or *Poultry War*, of 1537;

and also in 1548 when the turbulent *szlachta* tried to annul by force the marriage of Sigismund Augustus with Barbara Radziwill. In 1553, however, we find him in opposition to the court and thwarting as much as possible the designs of the young king. Nevertheless Tarnowski was emphatically an aristocrat and an oligarch, proud of his ancient lineage and intensely opposed to the democratic tendencies of the *szlachta*. A firm alliance between the king and the magnates was his ideal of government. On the other hand, though a devout Catholic, he was opposed to the exclusive jurisdiction of the bishops and would even have limited the authority of Rome in Poland. As a soldier Tarnowski invented a new system of tactics which greatly increased the mobility and the security of the armed camps within which the Poles had so often to encounter the Tatars. He also improved discipline by adding to the authority of the commanders. His principles are set forth in his *Consilium Rationis Bellicae* (best edition, Posen, 1879), which was long regarded as authoritative. As an administrator he did much to populate the vast south-eastern steppes of Poland.

See Stanislaw Orzechowski, *Life and Death of Jan Tarnowski* (Pol.) (Cracow, 1855). (R. N. B.)

TAROK, a game of cards very popular in Austria and Germany, and played to a limited extent in some parts of France. Special cards are used, and the rules are complicated. The name *Tarot* was originally given by the Italians to a certain card in the pack as early as the 13th century, but was afterwards applied to the game itself.

TAROM, a district of Persia, situated on the borders of Gilan, north-west of Kazvin. It is divided into upper and lower Tarom; the former, on the right bank of the Kizil Uzain (Sefid Rud) river, is a crown domain; the latter, on the left bank, forms part of the province of Kazvin. It produces much cotton and fruit, and derives a considerable revenue from its alum mines at Zajkanin. Most of the alum is exported to Russia. It also has a few olive groves. The inhabitants are Turks.

TARPAULIN, or Tarpauling (as if *tarpalling*, from *tar*, and *palling*, a covering, Lat. *palla*, a mantle), a heavy, well-made, double warp plain fabric, of various materials, used chiefly in the manufacture of covers for railway and other waggons and for protecting goods on wharves, quays, &c. To make it proof against rain and other atmospheric influences it is generally treated with tar, though various compositions of different kinds are also employed, especially for the finer fabrics such as are used for covering motor-cars. These covers are generally made of flax, hemp and cotton, and are very similar to canvas—indeed, large quantities of canvas are made waterproof, and then called tarpaulin. A very large quantity of tarpaulin is made entirely of jute. The chief seats of manufacture are Dundee, Arbroath and Kirkcaldy. Formerly the word was used as a sort of nickname for a sailor, the modern "tar" in the same sense being an abbreviation of it.

TARPEIA, in Roman legend, daughter of the commander of the Capitol during the war with the Sabines caused by the rape of the Sabine women. According to the common story, she offered to betray the citadel, if the Sabines would give her what they wore on their left arms, meaning their bracelets; instead of this, keeping to the letter of their promise, they threw their shields upon her and crushed her to death. Simylus, a Greek elegiac poet, makes Tarpeia betray the Capitol to a king of the Gauls. The story may be an attempt to account for the Tarpeian rock being chosen as the place of execution of traitors. According to S. Reinach, however, in *Revue archéologique*, xi. (1908), the story had its origin in a rite—the taboo of military spoils, which led to their being heaped up on consecrated ground that they might not be touched. Tarpeia herself is a local divinity, the manner of whose death was suggested by the tumulus or shields on the spot devoted to her cult, a crime being invented to account for the supposed punishment.

TARQUINII (mod. *Corneto Tarquinia, q.v.*), an ancient city of Etruria, Italy, situated on a hill overlooking the S.W. coast of Italy, about 5 m. N.W. of it. The site of the Roman town is now deserted, its last remains having been destroyed by the inhabitants of Corneto in 1307. Scanty remains of walling and of buildings of the Roman period exist above ground; traces of a large rectangular platform were found in 1876, and part of the thermae in 1829; it occupied the summit of a hill defended by ravines, called Piano di Civita. It seems probable, however, that the original settlement occupied the site of the medieval town of Corneto, to the W.S.W., on the further side of a deep valley. Some authorities indeed consider, and very likely with good reason, that this was the site of the Etruscan city, and that the Piano di Civita, which lies further inland and commands but little view of the sea, was only occupied in Roman times. The case would be parallel to others in Etruria, *e.g.* Civita Castellana (anc. *Falerii*) which also occupies the site of the Etruscan city, while the Roman site, some distance away, is now abandoned. The importance of Tarquinii to archaeologists lies mainly in its necropolis, situated to the S.E. of the medieval town, on the hill which, from the tumuli raised above the tombs, bears the name of Monterozzi. The tombs themselves are of various kinds. The oldest are *tombe a pozzo*, or shaft graves, containing the ashes of the dead in an urn, of the Villanova period, the oldest of them probably pre-Etruscan; in some of these tombs hut urns, like those of Latium, are found. Next come the various kinds of inhumation graves, the most important of which are rock-hewn chambers, many of which contain well-preserved paintings of various periods; some show close kinship to archaic Greek art, while others are more recent, and one, the Grotta del Tifone (so called from the typhons, or winged genii of death, represented) in which Latin as well as Etruscan inscriptions appear, belongs perhaps to the middle of the 4th century B.C. Fine sarcophagi from these tombs, some showing traces of painting, are preserved in the municipal museum, and also numerous fine Greek vases, bronzes and other objects.

Tarquinii is said to have been already a flourishing city when Demaratus of Corinth brought in Greek workmen. It was the chief of the twelve cities of Etruria, and appears in the earliest history of Rome as the home of two of its kings, Tarquinius Priscus and Tarquinius Superbus. From it many of the religious rites and ceremonies of Rome are said to have been derived, and even in imperial times a *collegium* of sixty haruspices continued to exist there. The people of Tarquinii and Veii attempted to restore Tarquinius Superbus to the throne after his expulsion. In 358 B.C. the citizens of Tarquinii captured and put to death 307 Roman soldiers; the resulting war ended in 351 with a forty years' truce, renewed for a similar period in 308. When Tarquinii came under Roman domination is uncertain, as is also the date at which it became a municipality; in 181 B.C. its port, Graviscae (mod. Porto Clementino), in an unhealthy position on the low coast, became a Roman colony. It exported wine and carried on coral fisheries. Nor do we hear much of it in Roman times; it lay on the hills above the coast road. The flax and forests of its extensive territory are mentioned by classical authors, and we find Tarquinii offering to furnish Scipio with sailcloth in 195 B.C. A bishop of Tarquinii is mentioned in A.D. 456.
